1. The engine illustrated in Fig. 3 is a combination of two oppositely arranged cylinder castings having an interposed crankcase, the walls of the cylinders having a longitudinal passage each, connecting the combustion chambers with the crankchamber by means of an inlet port. The pistons reciprocating in the cylinders open and close the inlet ports mentioned alternately. On the opposite side of the cylinder wall outlet ports communicating with exhaust passages are provided, which are also alternately opened and closed by the movements of the reciprocating engine pistons.

No. 1,000,128—to George F. Swain, Chicago, Ill.; granted August 8, 1911; filed January 28, 1909.

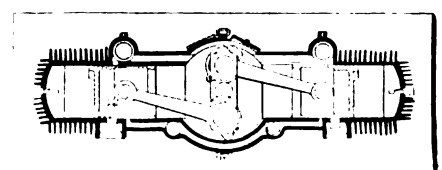

Fig. 3—Swain two-stroke cycle engine with opposed cylinders

Seen in the Show Window

EXHAUST horns utilize the pressure of the hot gases expelled by the motor, permitting the gases to by-pass from their regular path and to flow through a pipe or whistle, where the sound is produced. The Autolarm horn which seen at CA is placed betwen the motor and the muffler, a butterfly serving to close the way of the gases to the silencer and directing them to the pipe. Owing to its position the signal can neither clog nor jar loose. The material of which this signal is made is fully able to withstand the deteriorating influence of the motor exhaust, and especially because of the protected location of the horn the metal will not be attacked during its time of service, even if this should last as long as the life of the car the signal is installed upon. Operation of the signal is by means of a pedal arranged on the footboard in front of the driver, this pedal being connected to the signal proper through suitable wiring. It is made by the Gray-Hawley Manufacturing Company, 607 West Fort street, Detroit, Mich.

AS an example of a compressed-gas tank which will permit the chauffeur to keep the tires full of gas at all times the "Improved Baby" tank is shown at CB. It is filled with carbonic acid gas under a high pressure, the carbon dioxide being filled into the tank when in the liquid state. If the outlet is opened the "carbonic" gasifies and expands into the tire. The tank is made of steel of great strength, thus being capable to hold the gas under the high pressure obtaining in the vessel, which is more than 200 pounds per square inch. To inflate a tire, the hose connection is pressed against the tire valve and the valve at the end of the tank, controlling the outflow of the compressed gas, is opened by turning the nut seen in the illustration. Thereby, the carbonic acid gas is permitted to flow into the tube until the gauge attached to the tank indicates the desired tire pressure. Then a turn of the valve nut in the opposite direction closes the tank tightly. The "Baby" holds 4 pounds of gas all of which may be utilized in pumping up the tires of the automobile on which the carbonic-acid tank is installed, which is the product of the Liquid Carbonic Company, 432 Wells street, Chicago, Ill.

THE type of valve reseater shown at CC is being made by G. F. Crone, of 332 Genesee street, Buffalo, N. Y. It is, in a way, similar to a milling machine

CA—Gray-Hawley autolarm horn utilizes the exhaust gases of the engine
CB—The Improved Baby gas tank contains four pounds of carbonic acid
CC—The Crone valve reseater is built along milling machine lines
CD—Duplex folding pail is handy and waterproof and contains a strainer
CE—Almond flexible steel tubing may be used for many purposes on a car
CF—Ajax sliding door tire trunk for keeping tubes separately and protected

cutter, and cuts out the valve seat in the cylinder besides serving to true up the face of the valve. A brace operates the tools performing this work. The machine here illustrated is of a novel type, and contains an improvement in the shape of a vise holder which is fastened to the cylinder head while the face of the valve is worked upon.

A WATER pail which is collapsible so that it may be transported in the tool box and also provided with a screen to keep foreign substances out of the vessel into which the water is poured, is the description of the useful accessory shown at CD, this being the Duplex Folding Pail. The left-hand view shows the pail in the collapsed state and the right-hand one ready for use; the skeleton of the pail is of elastic metal bands and the material of the pail itself perfectly waterproof. This handy vessel is manufactured and sold by the Planet Company, located at 170 North Elm street, Westfield, Mass.

UNITING great strength with elasticity, steel tubing is fully on a par with flexible brass tubes, and the absolute absence of rigidity is seen at CE, where the Almond Flexible Tube is shown. This connection is of steel, and will render good service to connect carbureter and gasoline tank, gas tank and headlights, or the oil reservoir and the oil pump on an automobile. The T. R. Almond Manufacturing Company, of 1 Maple avenue, Ashburnham, Mass., is the maker of this article.

FOR transporting spare tire tubes on an automobile when touring, the tire trunk illustrated in Fig. CF may be used. It is made of a metal body covered with weather-proof fabric which serves equally well to preserve the tires in spite of the violent heat of the Summer sun and from oil which would otherwise spill over them through the carelessness of a driver. The trunk is strapped to the body of the car and is opened and closed by sliding down and up the door which is able to travel in a guideway. Thus the tubes are kept in a place by themselves, where they cannot be damaged by any tools or like apparatus; nor is there any danger of the tires being stolen from the trunk, because a lock of reliable make insures the owner against the intrusions of any interloper of the road. The trunk here shown is the product of the Ajax Trunk and Sample Case Company, of 91-93 Mercer street, New York City.

VOL. XXV NEW YORK—THURSDAY, AUGUST 31, 1911—CHICAGO No. 9

THE AUTOMOBILE

Records Fall at Elgin Stock Races

National, Mercer and Abbott-Detroit the Winners

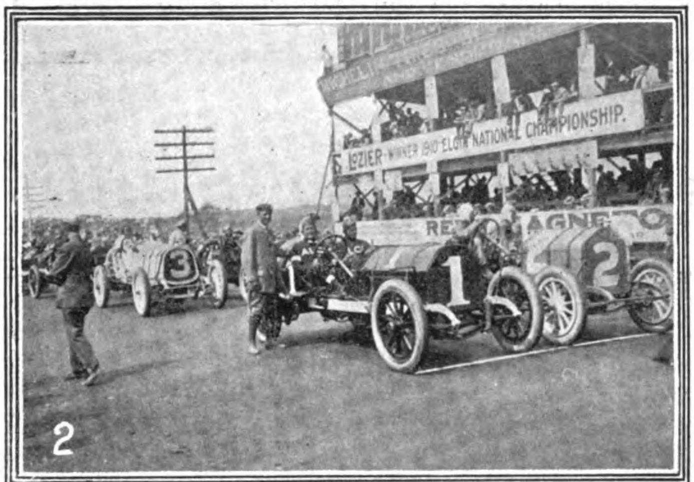
Fast time featured the two days' racing over the Elgin, Ill., 8.5-mile course, where the 1911 National Stock Car championships were decided on Friday and Saturday, August 25 and 26. With the exception of the race for 161 to 230 cubic inch displacement cars the times showed a marked reduction over those of last year.

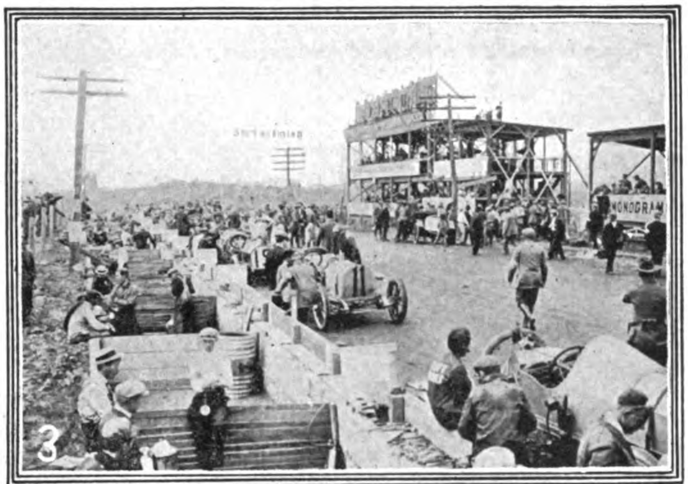
THE NATIONAL No. 2, DRIVEN BY LEN ZENGEL, CROSSING THE TAPE IN THE LEAD IN THE BIG RACE FOR THE ELGIN CUP

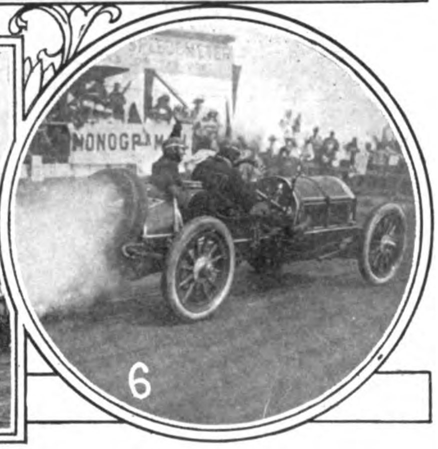
CHICAGO, Aug. 28—Four new champions were evolved from the running of the National Stock Chassis road races at Elgin, when National 2 (Zengel), National 1 (Herr), Mercer 15 (Hughes), and Abbott-Detroit, 33 (Roberts), received the magpie flag first in their classes. New marks were made in three of the four contests and the lap record of the course was sharply lowered by the Lozier entry (Mulford).

Shortly after the start of Saturday's contest, the Elgin National, ten sections of the grandstand collapsed, causing intense confusion and excitement for a short time and necessitating a new start. Fortunately no fatalities attended this mishap, although probably fifty persons were more or less hurt. The cars were sent on their way after fifty minutes of delay and within a few rounds several of the cars that had been prominent in practice were off the course for one reason or another and the race settled into a long grind to the finish. It was an easy victory for the National, with the Alco second, pushed out to the limit to beat the Mercer to the wire.

Over 40,000 witnessed the first day's events, which were run simultaneously, and on Saturday the crowd was estimated at 80,000. The manner in which the course was protected through-







2—Line up of contestants in the Elgin Cup race, which took place on the last day

3—General view of the competing cars at the pits preparatory to Friday's races

4—Lozier, driven by Mulford, on the round in which it broke the lap record

5—The troops were taken to their stations on the course in motor trucks

6—Mercer won the Kane County Cup and finished third in the Elgin

out the races, and the attention to detail reflected great credit upon the Chicago Motor Club, which managed the racing end of the program.

In a nutshell this tells the story of a meet that rivaled in excitement any that ever has been run in this section. As to the racing end of it, there was little competition in the four events, and only in the Illinois was the finish at all close, and in that it was a case of two teammates fighting for the cup and being separated by but 9 seconds. The Kane County event seemed made to the order of Hughie Hughes, who never was threatened, while in the Aurora Kulick in the Ford, which finished second, never was much of a factor. In the big race the early elimination of most of the stars robbed that classic of its chief interest, although not until Zengel flashed across the tape for the last time was it certain the cup was his. Grant and Hughes were so close to him that a stop of any duration in the final stages might have changed the result. In this race the contest feature was the fight for second place between Grant in the Alco and Hughes in the Mercer and at the end a matter of but 11 seconds separated the two.

Ten of the twelve entrants in the Elgin National started and of these only three were caught by the judges, while there still was one running when the race was officially ended. Zengel, the winner, averaged 66.45 miles per hour as against the 62.5 miles per hour of Mulford, last year's winner. In the Illinois, Herr in the National, went the 202 miles at an average rate of speed of 65.6 miles per hour, and of the four that started only the two Nationals caught the eyes of the judges. The Kane County brought out the biggest field of the meet, eleven of the sixteen entries starting and seven of them finishing, with Hughes showing an average of about 63 miles an hour. The Aurora cup brought out all three of its entries and all three finished, with Roberts in the Abbott-Detroit averaging 53.5 miles per hour.

The accidents that tended to mar the meet, came the second day, although the first was not without its mishaps. On Friday, F. E. Radina, mechanician for Raimey, in the Cino, in the Kane County, suffered a broken ankle, while Robillard, driver of one of the Stavers, had a close call when he hit a telegraph pole, cutting it down. But it was the second day that was blackest and that there wasn't a long death roll as the result of the falling of a section of the grandstand, was a marvel. The day started most auspiciously—weather made to order, immense crowds and intense interest among the spectators who filled the stand to its capacity of 6,600. The ten candidates for the national honors had come to the tape, had been lined up and sent away on their 305-mile run when the accident occurred.

Grant was about due to show above the crest of Britten's hill, just west of the stand, and the spectators stood up to watch him come over the brink. Then came the crash. Possibly the swaying caused by so many people standing at once started the trouble. The west section started to fall, or rather drop, the next followed suit and like a house of cards the western quarter of the stand went to the ground. It wasn't a terrifying sight to watch, either, for the fall was so gradual that one hardly appreciated the gravity of the situation. The spectators for the most part were so pinned in that they couldn't jump had they wanted to, and the big majority simply sat in their seats and waited for the inevitable. There wasn't must confusion about it, either, and the people in the east end of the stand hardly knew anything had happened.

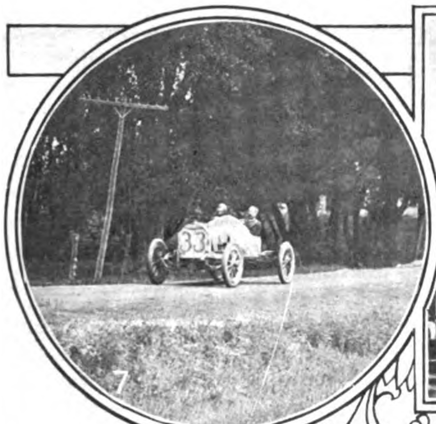
In all, probably 600 people fell with the stand and of these only forty were treated by the physicians who were on duty. The most serious injury was a broken leg sustained by one of the women spectators from Valparaiso, Ind., although three others had fractures that sent them to the hospital, one of the three being the daughter-in-law of Senator Lorimer. Probably fifty others were bruised or shocked, but none of them so badly that the physicians had to be called on.

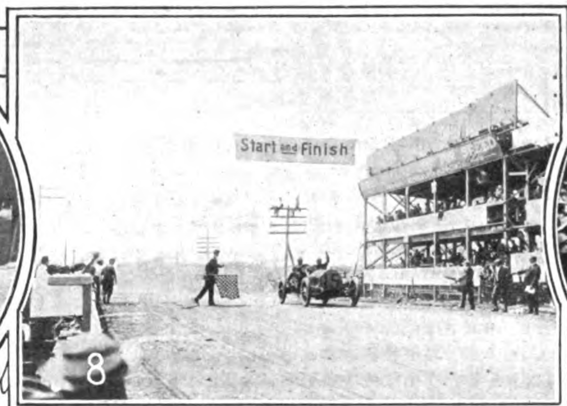
No official statement has as yet been given out as to the cause of the fall of the stand, but it is presumed that it was a case of too much haste in erecting the seats. The stand was a part of the big stadium used for Chicago's recent aviation meet and was used at Elgin last year. The aviation meet extending one day longer than had been scheduled because of the benefit given last Monday, the contractor was delayed in getting it to Elgin. In fact, he still had his men working on it when darkness came Thursday night and it was not until Saturday morning that he had put the awnings over the boxes. The Chicago Motor Club had nothing at all to do with the erection of the stands or with the receipts therefrom, that coming under the jurisdiction of the Elgin Automobile Road Race Association.

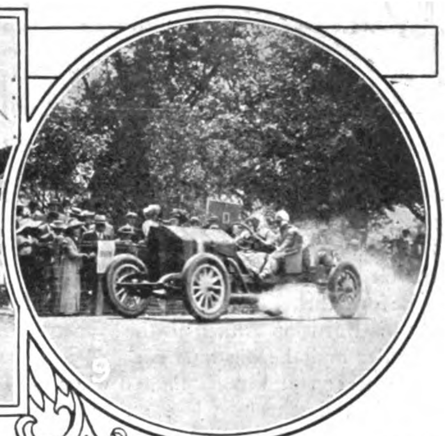
The fact that the race had started added to the general confusion, but the officials at once became masters of the situation. Referee Beecroft and Chairman Butler of the A. A. A. Contest board, at once ordered the race stopped, and one by one the cars were flagged and lined up at the pits. It was ordered that they be held there until the officials could learn more about the accident. That this was a wise act was apparent to all, for if the race had continued there might have been more trouble, especially in trying to get the injured to the hospital. Only one lap had been run so no one's chances had been injured. For the most part the drivers backed up the officials and Mulford and Wishart even went so far as to offer to help take the injured to the hospital. However, this was not necessary, the ambulance service being sufficient for the needs of the occasion.

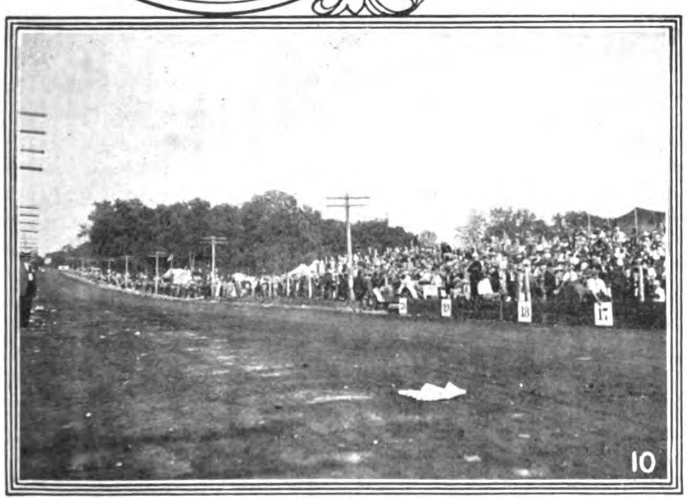
It was nearly an hour later before the second start was made, Grant in No. 1 Alco getting his signal at 11:50. Nine other followed him, the two absentees being the Cinos, one of which was put out in practice on Thursday when a broken connecting rod punched a hole in the crankcase. This caused Raimey to take Burt's place in the other Cino in the Kane County on Friday, but his accident in that race so damaged the car that it was impossible for it to line up with the others in the big event. This left Grant, Lee and Hartman in the Alcos, De Palma and Wishart in Simplexes, Aitken and Zengel in Nationals, Mulford in the Lozier, Buck in the Pope-Hartford and Hughes in the Mercer.

Right from the jump Mulford assumed the aggressive and from the way he burned up the course it looked as if he would repeat his last year's performance. He immediately opened a gap on the others traveling at a rate of 70 miles an hour. This he kept up for eight laps or 68 miles, when a burnt-out bearing put a piston and connecting rod out of commission and stopped the Lozier just at a time when its chances looked brightest. Mulford had one consolation, however, he pulled down the $200 cash prize given by the Stromberg Motor Devices Co. for the fastest lap. This came in the seventh round, which he negotiated in









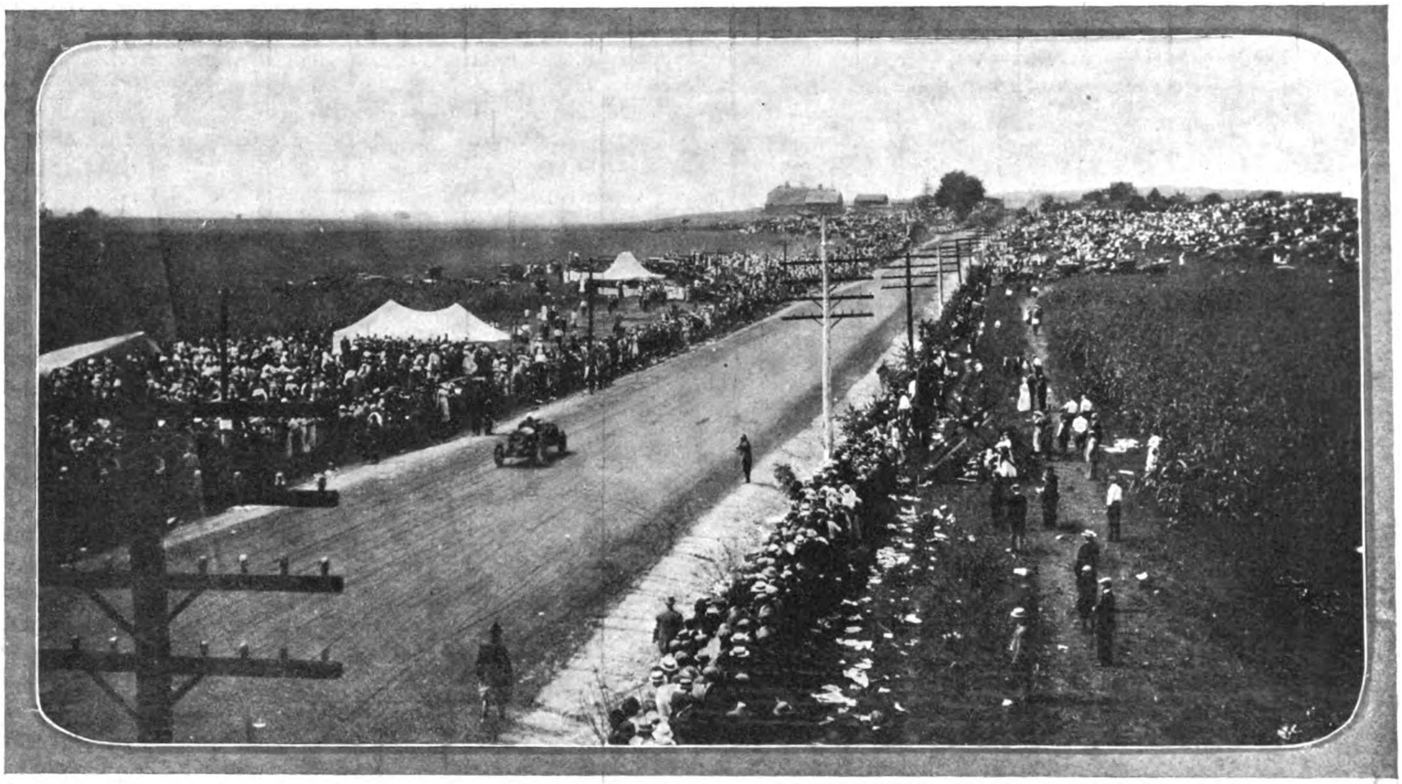
7—Abbott-Detroit, piloted by Roberts, which car won the Aurora Cup race

8—Mercer, No. 15, receiving the flag on the first day, winning the Kane County race

9—A bit of fast work by Herr in the National, which won the Illinois Cup

10—Giving an idea of the home stretch beyond the stand, and what a clear course means

11—Britton's Hill, a natural grandstand, which accommodated thousands on both days



Looking west from the top of the press stand—Britton's Hill on the right; showing Zengel's National at a 70-mile clip

7:13, equal to 70.4 miles per hour. His running was most consistent, his laps being 7:27, 7:14, 7:19, 7:17, 7:18, 7:17, 7:13 and 7:17—an average of 69.78 miles per hour for the distance he traveled.

Before this, however, there were others to fall by the way. On his third lap Aitken in the National went out with a cracked cylinder and the big blue car pulled up at the pit. In the same lap another star was eliminated when De Palma was put out with a broken flywheel. Close on the heels of these two mishaps came trouble for Wishart in the other Simplex, a burnt-out connecting rod bearing putting him out of the running when he was in second place. Then the race ran along to the twentieth lap before Hartman in the Alco was put out by a leaky gasoline line. At that time he was in fifth place.

All this time Buck was having tire troubles, much as did George Robertson a year ago in the Simplex. Even though the big Pope seemed to have plenty of speed the continual stops for tires put it out of the running. It was while Buck was fighting to make up some of this lost ground and perhaps get in for a position at the finish that the accident occurred on the back stretch. It was in his twenty-fifth lap and the big car was running over a fine stretch of road. The right front tire went and the Pope turned over completely and came up on its wheels again. Both Buck and mechanician Jacobs were hurled from the car. The mechanic was killed instantly but it was thought for a time that Buck's most serious injury was a broken thigh. He was taken to the hospital, where it developed that in addition his spine was broken and at 5:50 the end came.

While all this was going on Zengel, Grant and Hughes were battling for the cup. Lee and Hartman in the other Alcos never were important factors, but it did look for a time as if Grant might overtake Zengel. The Fairmount Park winner, however, was not to be denied. He kept everlastingly at it, never gave his rivals the least opening and from the time Mulford was eliminated to the end he always was in command. At the end of the twenty-first lap Zengel made his first stop, pulling up at the pit to take on gasoline. The next time around Grant came in and put on gasoline and water. Then the two again went at it hammer and tongs and at the thirty-second lap both made stops at the pit. Zengel took on a small quantity of gasoline, having heard a rattle in the tank that led him to believe his fuel was running low. This was not so, however, and he picked up the running again immediately. Hughes in the Mercer never stopped at the pits, but he did make one tire change along the course which did not take him long to accomplish.

The last lap was made interesting only by the fight for second place between Grant and Hughes. The Mercer went the last circuit 1 second faster than did the Alco, but that was not enough to land the place. Lee still was running and was in his thirty-third lap when Starter Wagner declared the race at an end.

The first day's racing was marked by the fact that all three winners—Herr, Hughes and Roberts—went through without a stop and also by the freedom from tire troubles, it being reported from the tire camps that only three cars suffered in this respect—two Stavers and Jenkins' Cole. The Stavers pinched tubes through not having racing rims, it is said. Not only did Herr go through without a falter, but Merz, his team mate, duplicated this feat. Merz was beaten 9 seconds for the cup and part of this loss is explained by his overrunning turns three times. Each time this meant a slight loss of which Herr took advantage. Merz often came by the stand at a tremendous clip and he testified to the great speed of the course by stating that several times he had the speedometer needle up to 100 miles an hour coming down the grade from Britton's hill to the stand. In this race the Stromberg $100 cash prize for the fastest lap was won by Herr, whose second lap in 7:23 was the best.

It was in the Kane County that the chief interest was shown, caused by the large field of starters. While Hughes was looked on as the favorite from the start, still it was thought he would have to fight to beat the Colbys, Coles and the others. The Staver people had hard luck in this. In the first place they were robbed by their best driver when Joe Nikrent, the Californian, was unable to start through having broken a belt in his engine base. Then Robillard went out when he hit a telegraph pole. This left only Monckmeier and that plucky youth kept plugging away and was the last one to catch the flag.

Of the eleven that started in this race, seven finished. Robillard went out in the seventh, as explained. Ogren, a new man in one of the Colbys, was eliminated by having his pistons seize in the sixth lap. Armstrong, another Colbyite, was running in his fifteenth lap when the race ended. The fourth car was the Cino, which was put out in the seventh lap when Raimey's tire trouble in the backstretch caused the Cino to pitch them both out. Raimey was somewhat bruised and mechanician Radina broke an ankle. Hughes' sixteenth lap in 7:41 won the Stromberg $100 prize.

Roberts, in the Abbott-Detroit, drove a pretty race for the Aurora cup, although in the early stages it looked as if A. M. Robbins, the Abbott dealer, who was driving his first race, would win. Robbins had gained the lead and was in front at the end of the third lap. In the backstretch a bolt in his magneto coupling broke and he lost 9 minutes fixing it. That lost him the lead. Later on another bolt loosened and more time was lost. These were the only bits of trouble experienced by the three contestants throughout the race. None of them stopped for tires or for supplies. Kulick ran consistently but never got close enough to Roberts to worry him. Roberts' fourth lap in 9:00.19 was the fastest and captured the Stromberg prize.

The time made in all four races was a revelation and the fact that three course records were broken is sufficient reward for the Elginites, who spent $6,000 on the homestretch alone. In the big race Zengel averaged 66.45 miles per hour for the 305 miles, whereas last year Mulford did 62.5 for the same distance. It is more than likely that even this would have been beaten had Mulford stayed in Saturday, for while he was running he was going but a fraction less than 70 miles an hour. Zengel's consistent work was in keeping with the schedule he had laid out and possibly he could have done better had he been pushed. The Mercer's average in the big race was 64.54 miles an hour.

In the Illinois cup race Herr did 65.6 for the 202 miles, a big increase over last year's Illinois, in which Livingstone, in a National, averaged 60.6 miles an hour. In the Kane County Hughes averaged 63 miles an hour for the 169 miles, whereas last year Buck in the Marmon won at 55.1 miles per hour. Hearne in the Benz won the Fox River cup last year at 54.1 miles per hour, which was just a shade better than Roberts did Friday, the Abbott's average being 53.5 miles per hour.

The manner in which the Chicago Motor Club handled the races was beyond any criticism—there wasn't a hitch anywhere. The guarding of the course was in keeping with the record made by the Illinois citizen-soldiery at Elgin last year and at Crown Point the year before. At all times the crowds were under perfect control and even when the grandstand fell there was no confusion or running across the course. The first day, perhaps, more soldiers could have been used but on the second day there were enough miliatiamen from the First Illinois Cavalry to give them complete command of the situation.

The timing and checking were first class. The Warner instrument was used in the timers' stand and not once did it slip a cog. There were eleven bulletin boards around the course on which the time was posted and so perfect did L. R. Campbell have his system working the second day that 70 seconds after a car crossed the tape at the finish of a lap the time was on all the boards around the course. The score boards were something new and those in the grandstand had a fine opportunity to study the scheme evolved by H. N. Fowler of the Chicago Motor Club. This big board was worked from behind. Under each car's number was a swinging board, pivoted in the center. The scorers placed the time on this board when it was turned to the rear by means of clips, the figures being already printed on cardboard. Then by swinging this little door it was turned to the front and the public could study the results easily.

The transportation of the soldiers and flagmen was handled by John H. Kelly, who had at his command several big trucks loaned by Chicago dealers, and there never was a hitch there. J. S. Woodworth again handled the flagmen, all of whom were motorcyclists, and this department worked with exceeding smoothness. As for the press stand that was a commodious structure, two stories high. The Chicago newspapers had the first floor and each paper was allowed three representatives there. Upstairs were located the visiting newspaper men and the trade press. There were three rows of seats on each floor, each raised above the one in front so that everyone could see without having to stand up. This stand was filled with more than 200 newspaper men. The publicity department furnished them with all the times and in addition secured official details of all the happenings along the course.

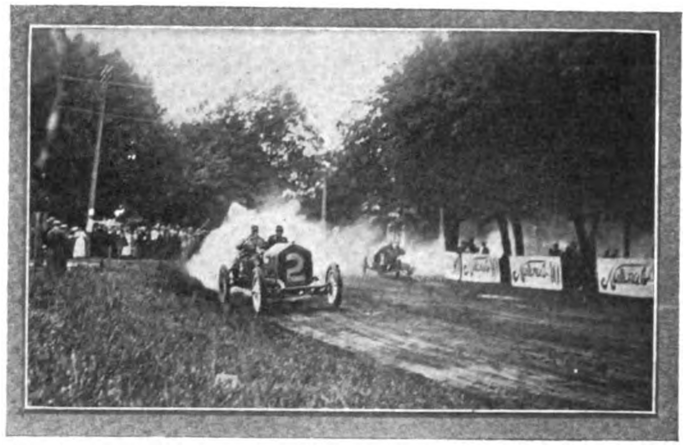
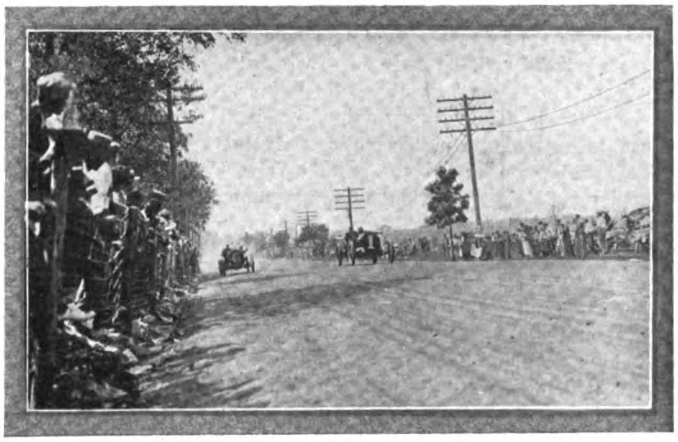
View of the line of pits in front of the main grandstand



National (Zengel) leading Alco (Grant) in making the Hoornbeck's turn



Alco (Grant) and National (Aitken) on the new turn west of grandstand

Another innovation introduced by the Chicago Motor Club was a distinguished guests' stand in which were placed prominent car manufacturers and others whom the club desired to honor. This stand was well filled on both days and the makers appeared to appreciate the compliment, this being the first time those in the industry who are responsible for the racing have been specially cared for at big meets.

A coroner's inquest was held Saturday night in Elgin and the jury returned a verdict holding no one responsible for the death of Dave Buck. "Dave" appears to have been a nickname given the Pope-Hartford driver. His right name was Richard Dudley Buck and he was 36 years old, his birthplace being Buchanan, Mich. Jacobs, the mechanic, was a chauffeur for J. L. Russell, the Chicago agent for the Pope-Hartford, who entered the car in the race.

How the Races Were Won

Illinois Trophy

Two Nationals and a pair of Velies were the only contestants in this event. The first time around the Herr National had gained 9 seconds on its teammate followed by Velie No. 4, with the Jeffkins Velie, well up, in the rear. At the end of the second round the Herr National, with one of the fastest laps of the race, swung into the lead, Merz falling into second place, the Stickney Velie and its mate following in the order named. This order was maintained throughout the third lap, at the conclusion of which Herr was leading his teammate by 22 seconds, with the Velie pair far behind. The conclusion of the fourth round saw Merz leading Herr by the smallest possible margin, with the rest of the field maintaining their respective

positions. This order was maintained throughout the fifth, sixth, seventh and eighth rounds. The end of the last named circuit found the Merz National leading by the meager margin of 7 seconds. This lead was overcome in the following round by Herr, who led at the conclusion of the ninth round with a margin of 12 seconds over the Merz National, with the Velie pair still falling back.

From this point on the race developed into a duel between the National pair for the honors, Herr in the tenth round increasing his lead to 42 seconds, to 53 seconds at the conclusion of the eleventh lap and to 63 seconds at the end of the twelfth round. In the thirteenth and fourteenth circuits Merz reduced his teammate's lead by a few seconds and was slowly but surely closing up the gap that separated him from the leader. The conclusion of round fifteen saw the Herr National leading by but a scant 20 seconds, which was still further reduced at the end of the sixteenth lap to 15 seconds. The Herr National gained slightly on the Merz car in the seventeenth, eighteenth and nineteenth rounds, but lost a trifle on the twentieth, Herr's lead at the conclusion of that lap being an even 25 seconds. Rounds twenty-one and twenty-two found Herr hanging on to his meager advantage with bulldog tenacity, the small margin of 35 seconds being all that separated the blue pair.

At this point Merz began a determined effort to overtake his mate, gaining 8 seconds on the next to the last round. When the times of the contending pair had been taken at this point it was seen that the Herr National had a lead of but 27 seconds and Merz went out to cut that down if possible. Herr was equally insistent on maintaining his advantage, and although Merz steadily but none the less surely gained ground he was unable to overcome the lead of his opponent. At the start of the race the Herr National had been sent away 30 seconds in advance of the National No. 3 and thousands of watches were flashed in the effort to keep tab on the flying pair. When Herr crossed the line in 185:55, thousands of glasses were leveled at the course to watch for the appearance of National No. 3 over the brow of Britton's hill. Slowly the seconds ticked off and just as 30 seconds had elapsed the blue bonnet of No. 3 shot into sight and came down the stretch at express speed, too late, however to win the race, Merz falling short of the goal by a scant 9 seconds.

Although the Velie pair was still running at the conclusion of the race, No. 2 had completed but 20 laps and No. 4 but 16.

Kane County Trophy

Eleven of the sixteen cars originally entered in the race for the Kane County cup faced the starter, the three Falcars having been withdrawn and the Staver-Chicago No. 16 and Cino No. 26 having been prevented from starting by accidents in practice earlier in the week. Mercer No. 15, driven by Hughie Hughes, jumped into the lead at once, gaining a substantial lead in the first lap over Cole No. 24 driven by Jenkins, which led Corbin No. 14 by a scant second, with Cino No. 11 close up and the Barnes Mercer trailing along behind the Cino. At the end of the second lap, however, Hughes' teammate swung into second position, being but 23 seconds behind the leader, the Corbin still maintaining third position, Staver-Chicago No. 27 moving up to fourth, Colby No. 20 into fifth and Cole No. 24 dropping back into the sixth notch. These relative positions of the contestants were maintained until the conclusion of the ninth round, Colby No. 18 having meanwhile dropped out at the sixth lap with a seized piston, Fred Robillard in a Staver-Chicago No. 25, coming to grief on the following lap when his car cut down a telegraph pole on the Hoornbeck turn as a result of a tire coming loose, and Ramey, in a Cino, also being eliminated when his car skidded on the backstretch, breaking his mechanician's leg.

The conclusion of the tenth circuit found the Hughes Mercer leading its teammate by 2 minutes, 2 seconds, Colby No. 20 being over 2 minutes behind the Barnes Mercer and Cole No. 24 about a minute behind Colby No. 20. For round after round the Mercer pair added to their lead over the other contestants, Hughes maintaining an advantage of about 2 minutes over his teammate throughout. From the sixteenth lap on to the finish Hughes gained steadily and the conclusion of the race showed him with an advantage of 2 minutes 34 seconds over Barnes, who in turn was 6 minutes 16 seconds ahead of Colby No. 20, which led Cole 24 by 2 minutes 8 seconds. Corbin No. 14, Cole No. 21 and Staver-Chicago No. 27, all completed the entire 20 laps, the latter being about 20 minutes behind the leader. Colby No. 22 was still running at the conclusion of the race, but was nearly 6 laps behind.

The performance of the leaders was remarkable for the almost entire absence of trouble of any kind, neither of the Mercer pair having been compelled to stop either at the pits or on the course for any reason.

Aurora Trophy

There were but three entries in the race [illegible]r the Aurora cup, Ford No. 32, driven by Kulick, being o[illegible] by a pair of Abbott-Detroits—No. 3, driven by Mortime[illegible]ts and No. 31 by Robbins. At the end of the first round [illegible]oerts. who had started 30 seconds behind his teammate, h[illegible] almost overtaken him, crossing the tape the first time aroun[illegible] but 4 seconds behind and overcoming the 15-second start of the Ford on the backstretch. The second round saw Roberts with a clear lead of 35 seconds over Robbins, with the Ford almost a minute behind. On the third round Roberts was compelled to stop at the pits and Robbins swung into the lead having an advantage of 17 seconds at the close of the lap. Roberts, however, soon regained the lead owing to the combination of a fast lap and magneto trouble experienced by his teammate on the backstretch. A repetition of the same trouble on the fifth lap caused Robbins to lose still more ground, his place as runner-up having been assumed by the Ford at the conclusion of the fourth round, from which point the order was Abbott-Detroit 33, Ford 32 and Abbott-Detroit 31 to the end of the race. With each succeeding lap Roberts added about 1-2 minute to his lead over the Ford and at the close of the race had a lead of 8 minutes over Kulick's car. At the end of the fifth lap the Ford had an advantage of more than 10 minutes over Robbins' car, and although the latter from that point onward gained ground consistently on its little rival it was unable to overcome the handicap caused by mechanical troubles in the early rounds of the race, and finished about 7 3-4 minutes behind the Ford.

Elgin National Trophy

When the cars lined up for the start of the big race it was noticed that the Cino pair, which had suffered severely in the previous day's races, had been scratched. This left ten cars in the field as follows: Alco No. 1, driven by Grant; No. 2 National, Zengel; No. 3 Pope-Hartford, Buck; No. 4 Simplex, Wishart; No. 5 Alco, Lee; No. 6 National, Aitken; No. 7 Alco, Hartman; No. 9 Mercer, Hughes; No. 11 Simplex, DePalma, and No. 12 Lozier, Mulford. The latter, starting out with the evident determination of not alone winning the race but of breaking all records as well, covered the initial circuit in 12 seconds less than his nearest rivals, National No. 2 and Simplex No. 4. DePalma's Simplex negotiated the round 14 seconds slower than did the leader, followed by Grant's Alco, Hartman's Alco, the Mercer, Lee's Alco, the Pope-Hartford and the Aitken National in the order named. The second round saw Mulford add still more to his lead, the end of that circuit showing him to be 26 seconds in advance of Zengel, who had displaced Wishart in the Simplex as runner-up. De Palma still maintained fourth position, with the Grant Alco in fifth place, 2 seconds behind, the remainder of the contestants trailing. The third round witnessed the elimination of two dark horses, Aitken's National going out with a cracked cylinder and De Palma's Simplex retiring to the side lines with a broken flywheel. At the conclusion of this round Mulford's advantage had been increased to 33 seconds over the Zengel National,

(Continued on page 366.)

How to Avoid Jersey on Tour South

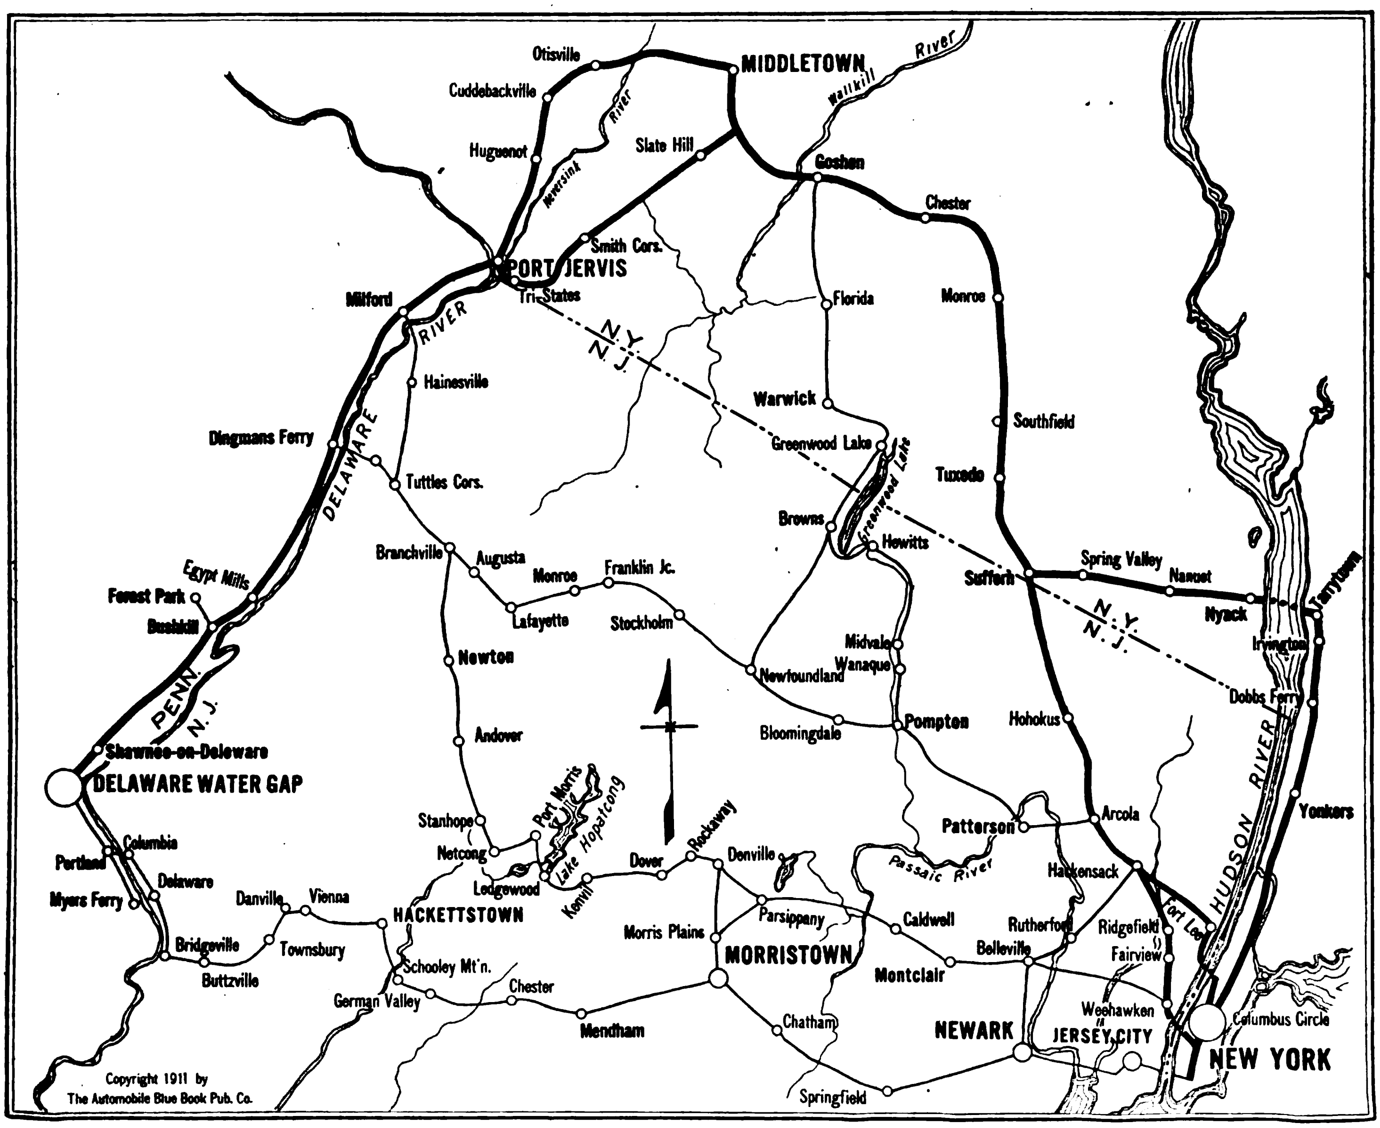
Delightful Trip Promises Much Pleasure

Embarrassments that confront automobilists in New Jersey under the present law may be avoided only by avoiding the State, and the accompanying article and illustrations show a diversity of routes around that State. The general directions are recommended by the Blue Book and the Touring Club of America.

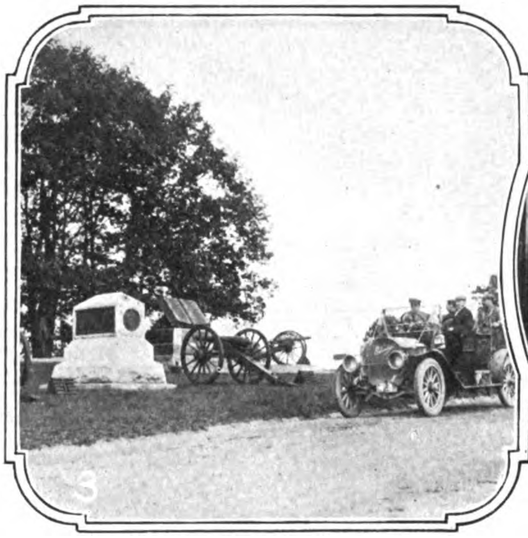
TO go south from New York City without traversing New Jersey [illegible] getting the license required there is a problem very [illegible] solved by taking the road to Tarrytown and crossing the Hudson to Nyack, Suffern and Middletown. In Volume I of the *Blue Book* this is Route 31, the all-New York route to Port Jervis, 96.3 miles. It is fine macadam practically all the way.

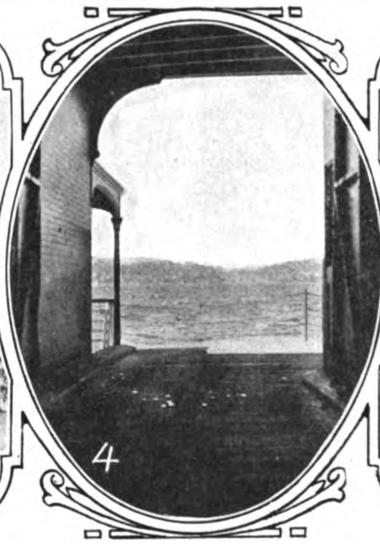
Few people will realize without a glance at the map that this variant is only 20 miles farther than the route via Hackensack and Suffern. In addition it is a more interesting country over which better time can be made. Except for those motorists who must take the most direct route to Philadelphia and vicinity this is a trip to be recommended. For the tourist who has leisure and no enthusiastic desire to "fork over" the requisite for a Jersey license it is the preferable way.

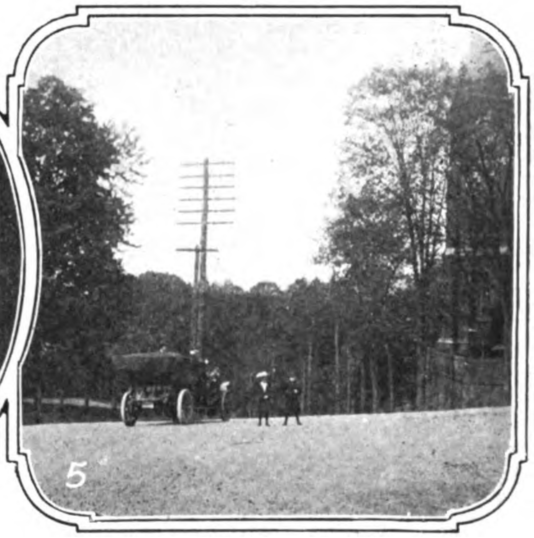
Leaving Manhattan by way of Riverside Drive and Broadway, the latter is followed all the way through Yonkers. En route Spuyten Duyvil Creek is crossed, so titled because a Dutchman swore to cross "en spuyt den Duyvil." There is a modern application of this phrase in taking this particular run "around New Jersey." At Yonkers is the old Manor House, now City Hall, while beyond at Dobb's Ferry a tablet marks Washington's head-



MAP SHOWING HOW THE AUTOMOBILE TOURIST MAY AVOID PUTTING TIRES IN THE SACRED PRECINCT OF JERSEY







1—After leaving the giant steel mills at Bethlehem, Pa.

2—A New York hillside road traversing a scene of peaceful beauty

3—Gettysburg, where Blue and Gray joined battle that shook the foundations of civilization

4—Nyack-on-Hudson, where Aviator Atwood made his last intermediate stop on his flight

5—Tarrytown, N. Y., one of the first and most beautiful of the road scenes to be enjoyed

quarters in 1781. Beginning here the lake-like widening of the Hudson River is called Tappan Zee, along which are situated Irvington, Tarrytown and Piermont, Nyack and Sing Sing. The Zee is ten miles long, and is crossed by ferry at Tarrytown to Nyack, three miles across.

All this region has been made classic by the pen of Washington Irving, one of the few American writers to achieve international reputation. His home, Sunnyside, is at Irvington, and is covered with ivy from a sprig presented by Sir Walter Scott. Paulding Manor and Lynnhurst, the residence of Jay Gould, are near by. In fact, it was said fifteen years ago that in the six miles between Dobb's Ferry and Tarrytown are the country houses of sixty-three millionaires, whose united fortunes exceeded $500,000,000. At Tarrytown is the estate of William Rockefeller, called Rockwood Hall.

Perhaps the most interesting place on the trip is Tarrytown. There is a monument commemorating the capture of Major Andre, and here is Sleepy Hollow, within whose immortal shadows stands the old Dutch Church (1699). In the churchyard Irving lies buried.

Running west from Nyack the car passes through a comfortable district into Suffern, on the New Jersey line, a small village, but a tourist center because of good roads diverging in five directions. On to Tuxedo, the most magnificent of suburbs, the route follows the Ramapo River. Beyond "Arden," the home of the late E. H. Harriman, turn left into Monroe, Chester and Goshen, thence to Middletown, up a beautiful valley into Port Jervis.

Port Jervis is at the junction of the three States, New York, New Jersey and Pennsylvania. The route to Binghamton, yet in its formative stage, will be the most important connection for travel to Syracuse and Rochester. Port Jervis is also in touch with the favorite section of the Delaware through Milford and Bushkill. All the west side of the river is bordered by natural shale, making a clean, smooth road, free from dust and not slippery. Some dangerous curves are encountered along this stretch of 27 miles, but accidents are few in spite of the constant stream of travel clear into late Fall.

An interesting old Indian fort is to be found across the old Barrett Toll Bridge which crosses the Delaware River into Pennsylvania, and there are a number of beautiful drives from Port Jervis along the Neversink Valley, Hawk's Nest Road and to Saw Kill Falls. High Point (1,600 ft.) is a picturesque resort, as is Lake Marcia, four miles to the east on the ridge of the Kittatinny Mountains.

Seven miles from Port Jervis is Milford, notable for the magnificent Pinchot Mansion with its fine driveway. The experiment station of the Yale School of Forestry is also located here. Numerous waterfalls are worthy of remark on this trip to Dingman's Ferry, with its old ferry and ruined bridge beside a modern iron one. Presently the Delaware makes its famous bend at Fiddler's Elbow, beyond which lies Bushkill, at the junction of the Big and Little Bushkill Creeks. The Falls of the latter are beauties.

Five miles beyond, at the fork near Delaware Valley Inn, the left road leads to Delaware Water Gap and the right turn leads to Stroudsburg. Various routes lead from these tourist centers to Wilkes-Barre, and Scranton or Easton and Reading southward.

Suppose that one had in view a trip to Washington or Richmond and Old Point Comfort. From the Gap a desirable route runs via Easton and Reading to Gettysburg. Fair dirt roads, numerous grades and bad water-bars characterize the 23 miles to Easton via Portland and Richmond, but the last ten miles are macadam. Easton is a manufacturing town on whose heights are located the buildings of Lafayette College, chartered in 1826. Good roads radiate to New York, Harrisburg, Philadelphia, Scranton. Leaving Easton on fine macadam which continues for 27 miles on the way to Reading, one passes through Moravian settlements, Nazareth and Bethlehem. From Allentown a fine road is followed through Kutztown, near the famous crystal cave, into Reading, a manufacturing city of German origin.

Southwest to Lancaster fair-to-good roads and pike with some stretches of macadam are covered; thence via York to the scene of the great Gettysburg battlefield of the Civil War, now fitly commemorated.

Whether one goes direct to Washington via Frederick on the fair pike, bad when wet, or takes the somewhat better route through Littletown and Westminster to Baltimore, considerable toll must be paid in Maryland. However, one hears occasionally that tolls are abolished, as, for instance, the two tollgates between Frederick and Knoxville, a road which is being macadamized.

The route from Washington to Richmond has been very recently described in THE AUTOMOBILE, and the most recent information regarding it may be obtained from the Touring Club of America. Starting east, then, on Broad street from Richmond, the notable battlefield of Seven Pines is passed on the 56-mile run to Williamsburg, on the peninsula. This was the ancient capital of the State and the seat of the Colonial Government. Points of interest are the Powder Magazine of 1714, old Christ's Church and the College of William and Mary, chartered 1693.

Forty miles out is Old Point Comfort, reached via Hallstead's Point. Warwick, Newport News and Hampton. St. John's Episcopal Church, built in 1658, of red and gray English brick, is one of the sights of Hampton, having a memorial window commemorating the baptism of Pocahontas. For it was her beloved Captain John Smith who sighted Old Point Comfort in 1678, and so named it in spite of the difficulties he subsequently encountered. Fort Monroe is, of course, one of the show places of the coast. Either the fine old fort or the large garrison attracts many visitors. And it is not without a thrill that the tourist looks out upon Hampton Roads, the scene of the engagement between the Monitor and Merrimac.

The Delaware capes and the resorts along the Chesapeake are particularly attractive late in the Summer and early in the Fall and all of them can be reached by the routes indicated herewith. The trip from New York to Old Point Comfort, via Port Jervis, Harrisburg and the south shore should make a delightful four-day tour. Of course it would be shorter via Jersey and will be as soon as the present law is changed.

The Rating of Gasoline Motors

Method Suggested by C. F. Dendy Marshall, B. A.

The rating of gasoline motors has occupied the minds of several of the leading technicians connected with the automobile art, but up to the present nothing definite has been evolved that will suit the ideas of everyone concerned. Simplicity of some formulæ brings with it drawbacks, while the complication of others renders them unsuitable. The suggestion contained in this article appeared in the "Automobile Engineer."

IT is impossible to devise a horsepower formula which will do more than give an approximation. Consequently anything in the nature of complications should be avoided, unless they are justified by unmistakable superiority. The same consideration applies to factors like d + a constant, where d is the diameter, and also to roots of the stroke, etc., which cannot be defended on any ground except that they profess to be based on the careful observation of different engines. I use the word profess advisedly, because anything more inconclusive than the first three diagrams in the recently issued report of the Horse Power Committee I cannot well imagine. The dots are literally all over the place, yet they are the record of observations from which the highly empirical formula proposed has been deduced.

There is an exceedingly simple formula which, under average conditions, is capable of holding its own with all the more complicated ones that have been put forward. By "average conditions" I mean within a fairly wide limit of engine speeds, for, if the engine is being overdriven it gives too high a result, but it does not seem to be limited to any particular range of dimensions, as far as engines have at present developed. It has been produced by several independent investigators, of whom I was not the first, though it is frequently associated with my name. I refer to $\frac{n\,s\,d^2\,v}{12{,}000}$ or $\frac{n\,s\,d^2\,v}{200{,}000{,}000}$, according to whether the dimensions are expressed in inches or millimeters. Here n is the number of cylinders, s the stroke, d the diameter, and v the number of revolutions per minute. It is derived from the "PLAN" of steam practice, and assumes the η p, or effective mean pressure corresponding to the brake horsepower, to be 84 pounds per square inch. η is a fraction representing the efficiency of the engine, and effects the change from i.h.p. to b.h.p. It may be objected that this assumption of the mean pressure is a large one to make, but the conditions are very different to the enormous range of pressures in steam engines of different kinds, and this is a fair average, and is, I think, fully justified by the results obtained. If the revolutions are unknown, and an idea of the power that would be obtained from a given engine on the road is sought for they may be assumed at 1,000, and the formula becomes $\frac{n\,s\,d}{12}$, or $\frac{n\,s\,d^2}{200{,}000}$. Strictly speaking this assumes that the product of ηp and the number of revolutions is 84,034.

This expression is superior to that of the R. A. C. $\left[\frac{n\,d^2}{2.5}\right]$ because, although the latter is considered on the theoretical grounds by its supporters to take into consideration both stroke and m.e.p. the practical result of it is that two engines with the same diameter and different strokes are rated the same, which is absurd, more especially in these days when the tendency is to increase the length of the stroke.

The committee's formula is put forward as "the maximum practicable b.h.p., as determined by a bench test under onerous but safe conditions." I gather it is based on the figures given by Mr. G. A. Burls in the paper accompanying the report. Now, it so happens that in his tables we can see very nearly what is the maximum power that has been obtained from many of the engines. For shortness, I will call the committee's proposed formula—i.e., .45 (d + s) .(d — 1.18) N—A; Mr. Dugald Clerk's modification of this, in which he multiplies it for the first factor —B; and the n s d² formula I shall in future designate as C.

Take engine No. 1. It developed by test at a piston speed of 1,275 feet per minute, 37 horsepower; at 1,535 and at 1,705, 41.5. We may take it, therefore, that 41.5 is about the most that can be squeezed out of this engine. The power by formula A is 67.2; by B, 40.3. By C it is 39.6 at 1,275, and 47.7 at 1,535, at which point the engine was already being overdriven. In the case of No. 2 we have 21 horsepower at 937 r.p.m., and 22 both at 1,205 and 1,340. Hence 22 is not very far from the maximum.

Formula: A, 63; B, 38; C, 22.4 at 937 and 29.5 at 1,205.

No. 3 is a large six-cylinder racing engine, developing 104 horsepower, at 1,666 feet per minute, which is 2,000 revolutions. It is probable that this is not very much below the maximum.

Formula: A, 163.4; B, 98; C, 121.

No. 4 gave 45 horsepower at 1,082, and only 47 at 1,333, so it is clear little would be gained by driving this engine faster.

Formula: A, 103; B, 62; C (at 1,082), 48.4

No. 5 gave 32 at 1,166, and only 33 at 1,417.

Formula: A, 48.5; B, 29; C (at 1,166), 39.8.

No. 6 produced 54 horsepower, at 2,040, which is 2,300 revolutions, practically maximum.

Formula: A, 80; B, 48; C, 57.

In No. 14 we have an excellent indication of the maximum, as it gave 87 at 1,416 and 1,600, dropping to 86 at 1,665.

Formula: A, 155; B, 93; C (at 1,416), 95.

No. 15 gave 32 at 960 32.7 at 983, and 30 at 1,035. Here again the limit is clearly shown.

Formula: A, 90; B, 54; C (at 983), 35.5.

No. 16 gave 37 at 1,160, and 37.5 at 1,320.

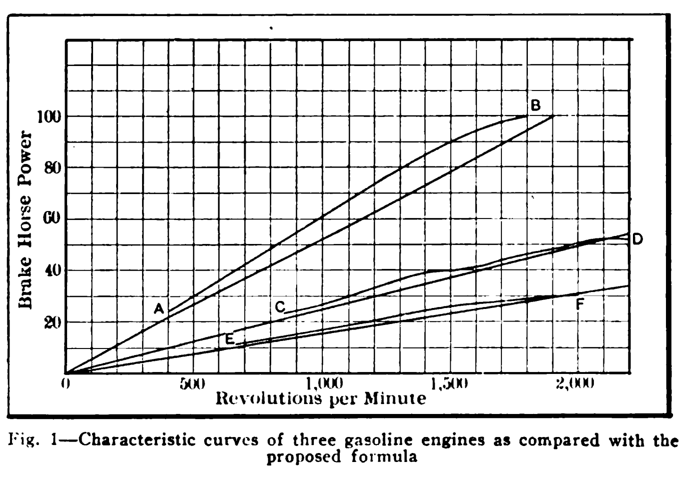

Fig. 1—Characteristic curves of three gasoline engines as compared with the proposed formula

Formula: A, 107; B, 64; C (at 1,160), 47.

No. 19 gave 202 at 933 and 204.5 at 955. Possibly this engine might have been pushed considerably higher, but I have worked it out because it is such an unusual size, namely, 12 inches diameter by 8 stroke.

Formula: A, 474; B, 285; C, 275.

No. 20 developed 108 at 1,120 and 109 at 1,200.

Formula: A, 264; B, 158.5; C (at 1,120), D, 143. The last two engines are both considerably below Formula C at all speeds. The cause is possibly bad cylinder proportions. In steam engines it has been found best for the stroke to exceed the bore, and I think the same holds good for these engines.

Nos. 27 and 28 are similar engines, except that one has four cylinders and the other six. It is a very remarkable thing that at five different speeds the powers should be *exactly* proportional to the number of cylinders. This is a case of practice agreeing almost too closely with theory, and one is inclined to suspect the accuracy of the tests, especially the last one, which is at 2,500 revolutions, when one would expect the six-cylinder to have rather the best of it. At this rate they are being driven to death, as No. 28 gave 47.2 at 2,000 revolutions, and only 41.2 at the higher rate of speed.

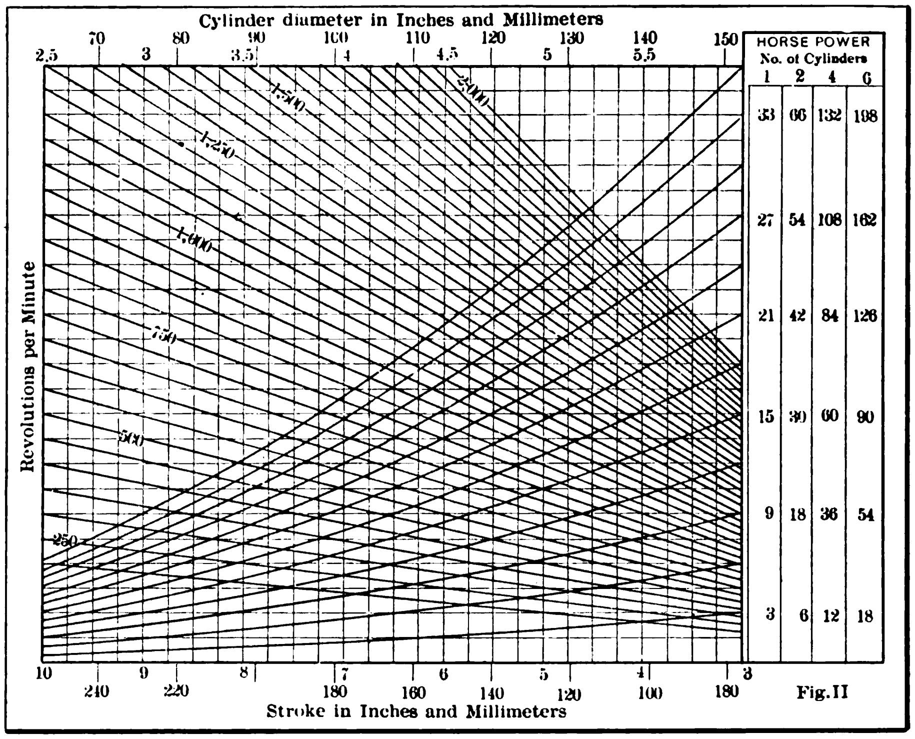

Fig. 2—Comprehensive chart showing the horsepower for various motors which can be read off at a glance, taking bare, stroke and engine revolution into consideration

Formula: A, 87; B, 52.5; C (at 2,000 revolutions), 45.7.

No. 29 gives us a maximum also, as the power was 37.5 both at 1,580 and at 1,900 feet per minute.

Formula: A, 70; B, 42; C (at 1,580), 39.

The series 37 to 40 are extremely interesting, because they are engines with 1, 2, 4 and 6 cylinders all the same size. Here the figures are very close to the proportion of the number of units, without being absolutely correct. As they do not seem to have been driven up to their maximum power, I have not worked them out. In fact, I have done enough to show, from its own figures, that the formula proposed by the committee is of very little use for practical purposes. It is true, I have only taken some of the cases, but as I have simply chosen those which show clearly within small limits what is the maximum power that can be got out of the engines, there is no reason to suppose that those selected are specially unfair to the formula.

I give below four others, which are interesting engines, and show how extraordinarily well the n s d^2 formula adapts itself to widely different types.

I. Sunbeam car; 6 cylinders, 80 × 120 mm.; b.h.p. 46 at 2,000 revolutions.

Formula: A, 92; B, 55.2; C, 46.1.

II. Panhard motor for Lebaudy airship: 4 cylinders, 185 + 200 mm.: b.h.p. at 1,000 revolutions by test 128, by formula C, 136.9.

III. Gnome aeroplane engine; seven revolving air-cooled cylinders 4.3 by 4.7 inches; b.h.p. at 1,000 revolutions, 50 by test, 50.7 by formula C.

IV. Westinghouse motor for petrol-electric railway cars; 6 cylinders, 140 × 160 mm. At 950 revolutions, 90 by test, 89.4 by formula C.

The results of all the above figures seem to be that the Committee's formula for maximum horsepower more often than not works out at about double what can be obtained on test; that Mr. Clerk's modification, which is supposed to be the power usually to be expected on the road, gives somewhere about the real maximum, and that the one I have always advocated is slightly too much at high rates of revolution. The reason for this is not far to seek. When an engine is being tested at various speeds, after it has got into its stride, the horsepower rises steadily with the revolutions, until a critical speed is reached, after which it goes up more slowly, finally coming down again. Fig. 1 gives the characteristic curves of three petrol engines. The line AB is that of a six-cylinder Napier, cylinders 4 1-16 by 7 inches. By the committee's formula it should be capable of developing over 156 horsepower. CD is from a four-cylinder Sunbeam, 95 by 135 mm., and EF from a Crossley engine. The straight lines adjacent to the curves represent the n s d^2 formula for each engine. If it is desired to estimate the maximum power by this formula, and the revolutions are unknown, it can be done more or less accurately by assuming a number for them, based on experience, and the dimensions and design of the engine. Fig. 2 is a chart giving the horsepower by the n s d^2 formula.

This is used as follows: Enter at the bottom of the measurement for stroke, and run up until the correct revolution line is intercepted, then pass horizontally to the right and take the curved line which starts at the point of arrival. First, I will assume there is one just right. Go down it to the left until you are under the diameter on the top scale. The height of this point from the bottom gives the horsepower at the right side. If there is not a curve available, and it is necessary to interpolate, it is quite easy; you estimate the ratio in which the point arrived at divides the space between the two adjacent curves, then the required point below the diameter will occupy a similar position.

To take a practical example, the horsepower of the Sunbeam, my No. 1, is found as follows: Enter at 120 stroke and pass up until you intercept the 2,000 revolution line, then go across to the right. This lands you just about midway between two curves. Follow the curves back until immediately beneath the diameter, 80 mm., and take a point just below halfway between them, then run across to the right, where you arrive at 46 horsepower. It is worth pointing out that the exact equivalent for the constant 12 when millimeters are used is 196,634. The effect of taking the round number of 200,000 gives a result just under 1 3-4 per cent. lower, which is quite near enough for all practical purposes, a variation which, of course, is quite negligible, considering that an approximation is all that one can aim at in devising a formula.

Accidents Come in Groups

A Chain of Disasters Often Caused by a Single Mishap

When the connecting rod cap bolts fail the damage is liable to involve many more parts than those originally affected. A small amount of play in this part of the motor will give rise to rapid wear, which will result at first in a knock and afterwards in disaster. Neglect may be dangerous and the knock should be eliminated as soon as it appears.

IT is an old saying that misfortunes never come singly, and in many ways the saying has borne itself out in facts, but in such cases it may have been remarked that the misfortunes were to a large extent dependent upon each other and followed along in a natural sequence which could not be interrupted. A chain of accidents may hinge upon some peculiar condition caused by a derangement of one of the component parts of a machine which has been the result of a very trivial cause.

A glace at the broken crankcase in Fig. 1 will show to what extent the damage may be transformed from one which would be easy to repair to one which requires the replacement of several parts. The connecting rod cap is shown to be broken off and this is what caused the rest of the damage. After being freed from the crank bearing, the connecting rod knocked the piece from the side of the crankcase walls. Another case is shown in Fig. 2, where the connecting rod has been driven through the walls of the cylinder owing to a broken bearing cap.

The last-named accident happened to a car with a horizontal engine and is, of course, only to be repaired by buying a new part. In the former, where the connecting rod has pierced the walls of the crankcase the repair may be made by bolting a cover over the fracture and fitting a gasket so that the patch will be oil-tight. There is always a mist of oil present in the crankcase even if the lubrication system should not happen to be the splash method of lubricating, hence a gasket or some other form of packed joint should be used in placing the cover over the hole.

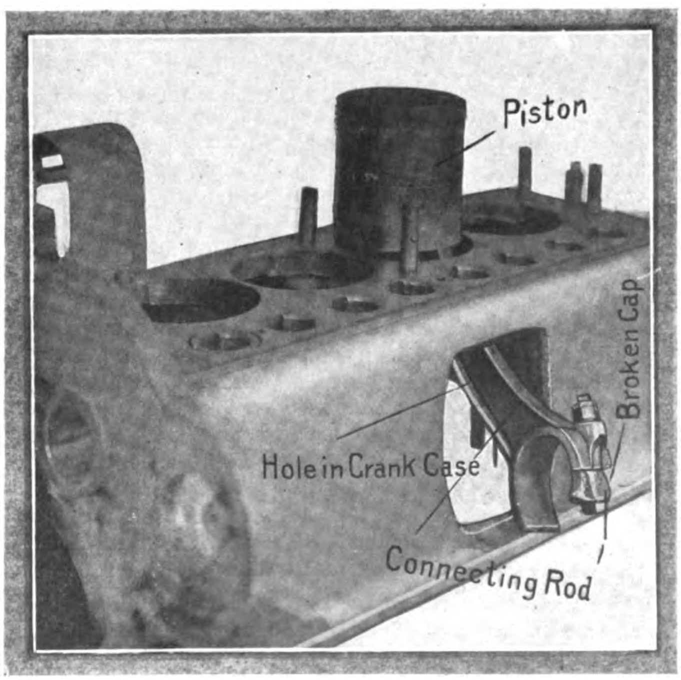

Fig. 1—A case where a broken cap bolt was responsible for further damage. The connecting rod has pierced the crankcase wall

In ordering a new part for a repair, such as the accident to the horizontal cylinder would necessitate, the piston should accompany the cylinder so that a proper fit is obtained. It will often be found, however, that the piston is sent, placed within the cylinder as shown in Fig. 3 (which is the new part to replace the broken one), and that some sort of lubricating matter has not been placed on the piston before it has been inserted. As a result, when the piston reaches the repairman he is unable to withdraw it. The illustration depicts a futile attempt which was made to withdraw the piston by placing a rope around the wrist pin and pulling thereon. The cylinder had to be soaked in kerosene for twenty-four hours and the piston hammered loose before it could be removed. It had rusted in the cylinder.

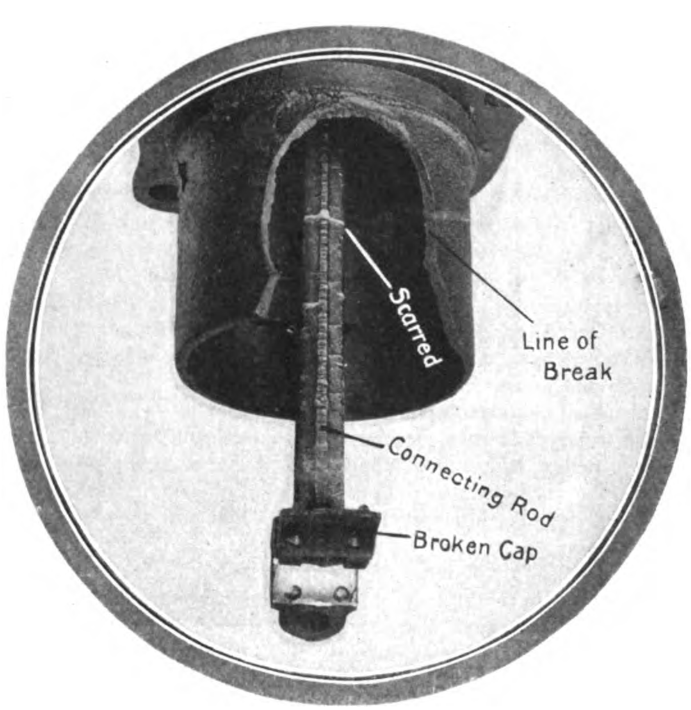

Fig. 2—Illustrating a broken cylinder which was caused by the failure of one of the connecting rod bolts. The following revolution of the crankshaft drove the connecting rod through the cylinder

Broken connecting rod caps, while not a common occurrence, generally cause much more damage than just that to themselves. As the connecting rod is released it will swing loosely as a pendulum from the wrist pin, the revolving crankshaft will come around and hit it a series of blows which will have sufficient force, as a rule, to send it through any metal which may be in the way, if the motor is not stopped in time to prevent several blows. Very often one revolution is enough to do the damage.

The connecting rods themselves are naturally very much battered up after an experience of this sort, so that the list of articles requiring replacing will naturally include one of these. An inspection of the two illustrations which show the broken parts will give an idea of the grinding and twisting to which the connecting rods were submitted; they have resisted the force of the blows better than the brittle castings, which was to be expected, owing to the inherent difference of the qualities of the material. In fitting a new connecting rod great care must be observed that it is of the same length as the others for a slight difference in length will make an appreciable difference in the clearance volume, which will materially influence the amount of compression. Trouble of this nature will not, as a rule, annoy the purchaser of spare parts, as the product of the factory will be found to be so standardized that interchangeability will be a matter of course; still where several years have elapsed between the time of replacement and the model of the machine a comparison should be made before fitting.

The connecting rod bearing cap is generally fastened by means of two bolts which are placed in bosses one on either side of the crankpin bearing so that the piston may be conveniently

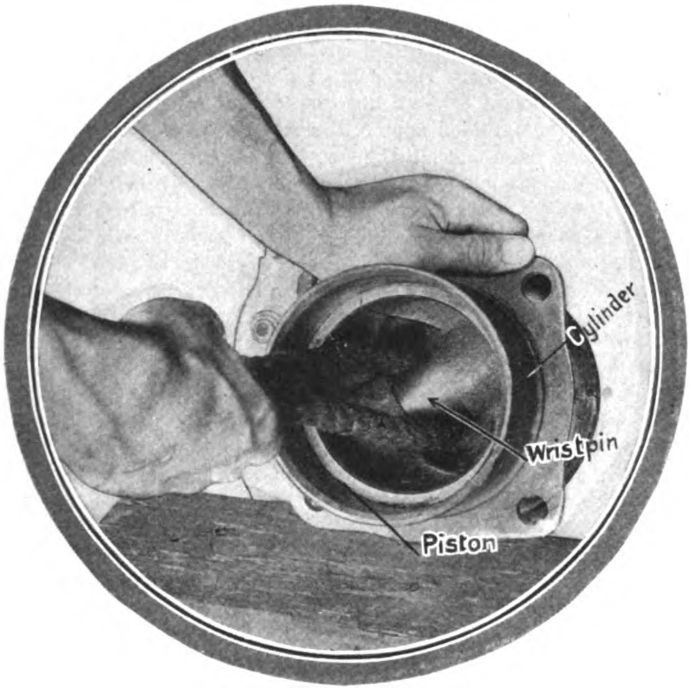

Fig. 3—Method used in an attempt to remove piston from cylinder. This means proved inadequate, as the piston had rusted within the cylinder

withdrawn as shown in Fig. 4. These two bolts are subjected during the power strokes of the motor to practically no stress at all since the rod is under compression and all strains are taken up by the crank bearing. There are certain parts of the stroke, however, where the connecting rod is in tension owing to its inertia, for instance, when after reaching the bottom of the power stroke the tendency of the connecting rod is to continue traveling in the same direction, it is checked by the upper part of the crank bearing which swings about and pushes the connecting rod and piston up into the cylinder. During all this time the rod is under compression and there is no strain on the bearing cap bolts, but when it has reached the top dead center an explosion takes place in another cylinder and pushes the crankshaft around. This will pull the connecting rod down and with it the piston which will put the rod in tension and place the strain on the cap. All the strain on the connecting rod caps is taken up by the two bolts when the rod is in tension.

The changes from compression to tension in the rod and hence in the rod attachments will be very sudden and it is evident that a very small amount of play in the bearing cap connection will cause rapid wear on account of the high inertia of the heavy moving parts, which, instead of being gradually reduced to zero as they would be in a case where there is no play, are brought to rest with a jerk which takes the effect of a hammer blow. It is impossible to bring a moving body instantaneously to rest. The lapse of time may be almost infinitesimal in the case of a light body moving at low speed, but the kinetic energy must have had time to dissipate itself either by being brought to rest slowly by the action of a contrary force or by impact with another body in which case there will be an elastic vibration set up which will consume some of the energy while the rest will be converted into heat. This latter is what takes place in a bearing in which there is excessive play and where the inertia forces are large, as they are in the case of the connecting rod bearing. The continuous impinging of one part against the other will cause a wear which will cause more lost motion as time goes on and will eventually develop a distinct knock in the motor. This is the danger signal and the wise motorist will heed it and search until he has found it.

Since the two bolts in the bearing cap take all the tension to which the connecting rod is submitted and are not subjected to any other appreciable stress it is evident that they should be large enough so that each be one-half as strong as the rod, plus a small additional factor of safety for wear.

Failure of the connecting rod is not very common for a variety of reasons, the greatest among them being that common practice has evolved a connecting rod which is somewhat heavier than actually required, and makers are not very anxious to tempt fate by cutting down weight in this part of the mechanism. All the force of the explosion is carried from the piston head to the wristpin and by means of the connecting rod to the crankshaft. When the ignition is early the strains endured are greatly augmented, especially if it is so early that a pounding results and places a severe compressive stress on the rod. If failure should occur, however, as is always possible, it would be in the nature of bending instead of crushing as is ordinarily assumed, since the connecting rod is a column.

It is very likely, as stated at the head of this article, that should the connecting rod fail, damage on a much more extensive scale than merely that to the original parts affected would be almost sure to result, but it nearly always starts in a small amount of play in some vital part and the careful man may save great expense by attending to the first small knock. The illustrations in Figs. 2 and 3 shown herewith are from photographs taken at R. M. Owen's repair shop, 1759 Broadway, New York City.

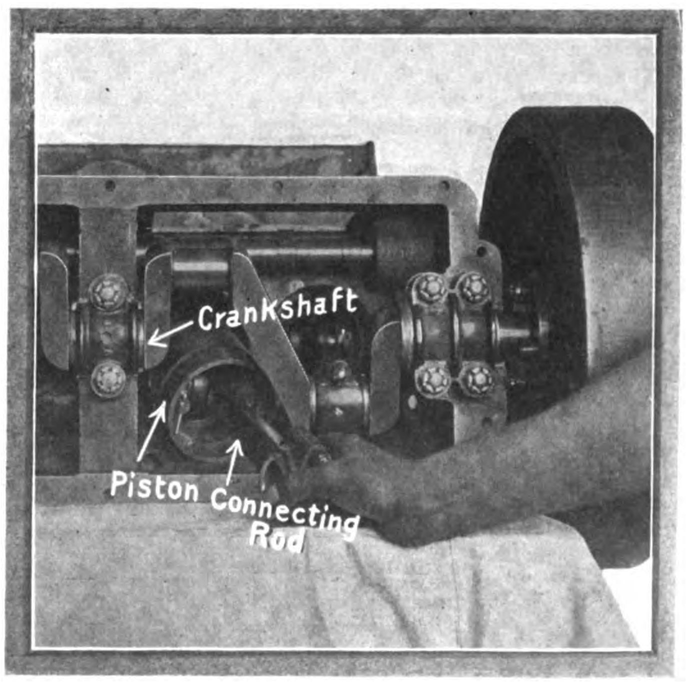

Fig. 4—The piston, connecting rod and attached parts may sometimes be withdrawn by removing the connecting rod bolts

Convertible Body for Depot Work

A Design Adapted for Suburban Use

Besides the carrying of passengers there will be of necessity a great many pieces of baggage to be carried to and from the depot. The body shown and described herewith, designed by George J. Mercer, is intended to meet all the exigencies of suburban service, both as regards passengers and their luggage.

THE requirements of a car which is designed to carry passengers to the railway depot in the morning from their places of residence and in the other direction in the evening, not to mention the various trips in either direction during the day with a stray passenger or two, are various. Such a vehicle must have room for trunks, as there is generally no express depot in the rural districts and all the hauling is done by the local liveryman. To maintain a horse service besides the automobile would greatly impair the efficiency of the scheme, as it would double the cost, while an all-horse outfit would be cheaper than the combination.

The problem could readily be solved, it is true, by maintaining two or three automobiles with different types of bodies, and that is what is generally done under the circumstances. This, of course, entails a large first cost and also an increased cost of upkeep and has been without doubt the cause of a great many suburban liverymen not having adopted the automobile service with its many advantages of speed and flexibility. To meet these requirements the convertible body has been suggested.

The body may be arranged in three different ways which are depicted in the accompanying illustrations. Fig. 1 shows the car arranged with two seats and a top which may be folded down at the convenience of the driver; when folded down as it is shown in the cut, the top takes up the position which is indicated by the dotted lines. When arranged in this manner the car is adapted to four passengers and the space at the rear will carry a small amount of luggage which will in quantity be more than the amount usually carried by four average passengers.

The next illustration, Fig. 2, shows the body arranged as a wagonette with side seats in the rear part of the wagon which are each capable of holding three persons, making a total of six passengers in the rear and two on the driver's seat, or eight altogether. A top which is provided with side curtains is fitted on this model so that in case of a storm they may be lowered and the passengers protected. A celluloid curtain protects the driver, so that in the way of protection in all kinds of weather, a point most necessary in this work, this car is amply protected.

The entrance to the rear part of the car is effected by means of a step which is lowered only when it is required. At other times it is kept folded against the rear of a tool box which is carried suspended beneath the car. The step is shown in dotted lines in its two positions in relation to the tail gate, which is also lowered when required and provides the landing step.

When used solely for trunk-carrying purposes the body is arranged on a purely wagon basis even so far as having side wings, as shown in Fig. 3, in case the packages are of great bulk or if there are a great many of them. The loading space back of the seat and inside the tailboard is 3 feet 10 inches long, and the wheelbase on the chassis is 114 inches in length. The chassis is of runabout type with the steering column sloped at 45 degrees and shortened so as to place the driving seat 24 inches from the dash.

There are a great many people who are located in various parts of the country at a distance of between twenty-five and seventy-five or even more miles from large cities who make their living during the Summer by carrying passengers to and from the railway station, besides having a contract with an express company to deliver all goods which are directed to houses within the district covered by the wagons. Outside of the actual passenger traffic there is the consequent baggage, which amounts to a large item since there are a number of transient visitors to these suburban places who stay perhaps over a short vacation period or merely for the week end. In a great many cases along the seashore the coast line is so irregular that the railroads do not attempt to follow along its deviations but content themselves with running their line about a mile inland so that they can operate with as few bends as possible. The people who live in the country districts will be found to greatly favor the vicinity of water. This is especially the case where the inhabitants are largely made up of those who live in town during the Winter and along the water front in the Summer. Owing to the irregular shore line there are many spots where the railroad is at a very great distance from the homes of the passengers.

The service given by the horse met the exigencies of a two-mile trip as well as could be possible, making the trip in fair time and being very reliable except in extraordinary cases. Above this distance, however, a trip to the depot became more or less of an ordeal for the commuter so

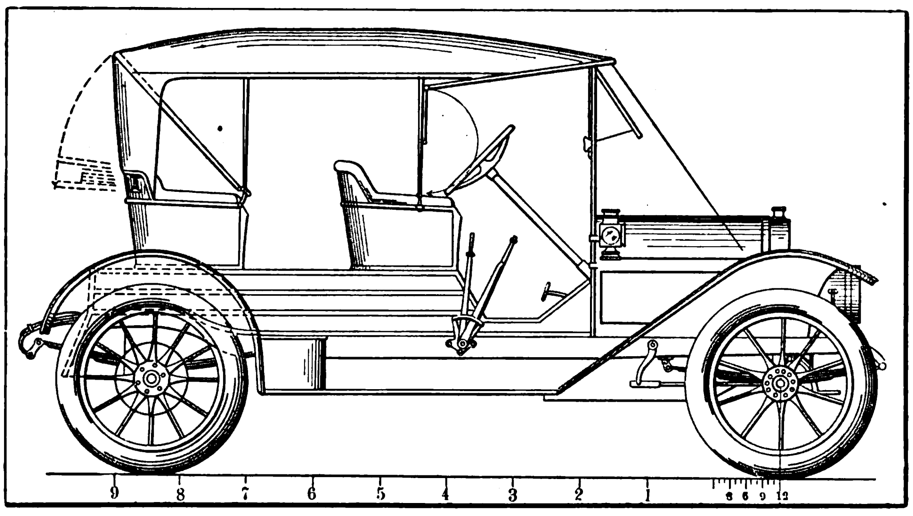

Fig. 1—Showing the convertible body as a two-seated passenger car

that he was prone to pick out a less favored spot in order to bring himself within such a distance of the depot that he may spend a fair part of the evening in sleep instead of making a hurried rush in the early dawn for a train that will take him to town in time for the opening of the business day. The coming of the automobile has gone far to revolutionize these conditions and a trip of even five miles has no terrors for those who are in reach of its services. In a great many cases the Summer visitors have their own cars, but on the average there is a very large number who are not so provided and who would appreciate an up-to-date liveryman who would provide the rapid service which is possible with an automobile. To maintain a service which would take care of both passengers and baggage it is necessary as a rule that vehicles of large capacity be used. This will depend, however, on the demands due to the size of the population.

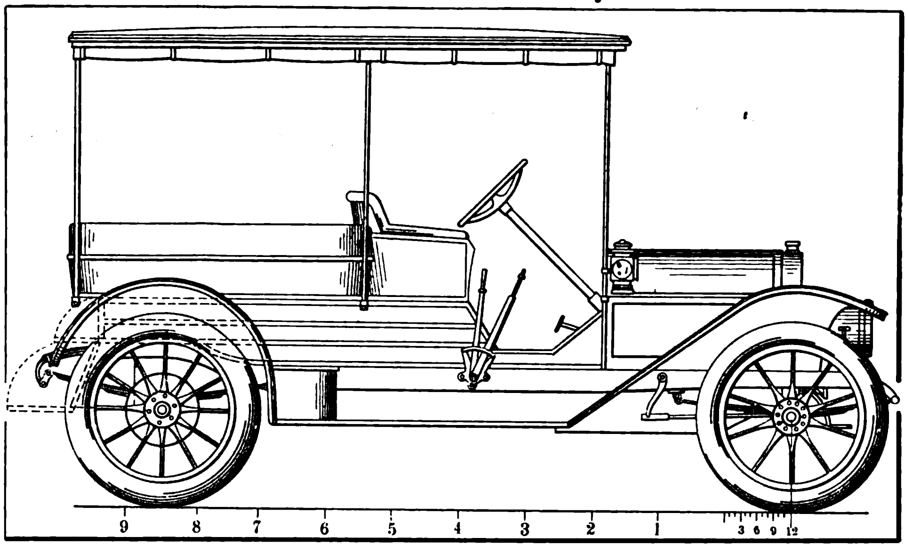

Fig. 2—The convertible body is shown as a wagonette, with space for six passengers in the rear and two in the driver's seat

From this description and the illustrations which accompany it it is evident that it is possible to have a convertible body for this type of work which, besides possessing ability, will present a neat appearance.

Gas Generator Needs Care

The parts of the gas generator which are located in such a position that they are apt to be subject to lime deposits need constant care so that their action is not prevented by the subsequent clogging. Occasional attention will go far toward prolonging the life of the generator.

THE parts of the carbide carrier which come in contact with the water distribution apparatus are liable to clogging by the formation of lime residue in the generation of gas. If this residue is allowed to collect, it will have to be removed with a chisel, which is a delicate operation in a light construction like that of a generator, especially around the water valve or its outlet. Acids are sometimes used to remove the deposit, but as they eat the metal, their use should be prohibited. The basket and pot should be thoroughly washed out after each run with water, the water outlets being cleaned with special brushes, when these are obtainable, or by wires, removing all traces of lime. The water valve should be scraped and tested to see whether it seats properly, care being taken not to damage the valve or its seat in so doing. While the valve is dismounted for cleaning it would be well to see that its stem is straight and that it works with some ease in the threaded portion attached to the water chamber. The gas valves should be cleaned and should seat snugly, so that there will be no leakage past them. This applies also to the gas valves on the lamps. It must be remembered that the best polish on the outside of the brass work has nothing to do with the condition of the interior.

The best position for the generator is on the running board just back of the change gear quadrant, and sufficiently far out from the frame to allow a free circulation of air all around it. The generator will keep cool in this position and will perform its work to the best advantage when properly cooled.

English Taxi Chauffeurs Not Workmen—A bill recently introduced into the House of Commons has to do with a recent decision of the House of Lords, to the end that taxicab drivers are not entitled to the benefits of the Workmen's Compensation Act, 1906, on the ground that they are not "workmen" in the legal sense of the word. The bill is intended to reverse the decision.

Letters Answered and Discussed

Wants to Darken Brass

EDITOR THE AUTOMOBILE:

[2,797]—Some weeks ago I saw a statement that olive oil added to some other ingredients and applied to brass would darken same and hence relieve one of the necessity of polishing it. I have lost the copy of the receipt and am asking you therefore to repeat the receipt. J. M. D.

Bowling Green, Ky.

A receipt published recently in these columns was as follows: Dissolve 100 parts of copper nitrate in from 100 to 200 parts of water; it is possible to form a solution in which the parts may be immersed or if too large the solution may be painted thereon. Then drain or shake off the surplus solution and heat the article so as to decompose the copper salt into a black copper oxide. The heating can be carried on over a clear charcoal fire or in a closed muffle furnace.

Small Cylinder Design

Editor THE AUTOMOBILE:

[2,798]—Could you tell me through your letter department how to figure the amount of iron in the cylinder of a four-cycle, single-cylinder, air-cooled motor of motorcycle type? What is the thickness of the cylinder at the combustion chamber and at the side walls? Give formula for calculating the size of the connecting rod and piston of a motor 3 3-4 x 4 inches and tell me what are generally the length and thickness of the flanges? How is the cylinder fastened to the crankcase and what is the formula for determining the size and weight of the piston for this size of motor? H. E. RIEGEL.

St. Paul, Minn.

A cylinder of the size mentioned in your letter would be about three-eighths of an inch in thickness. The cylinder head in a cylinder of this size would be cast with the walls in one piece and would be of the same thickness.

If a plain rectangular connecting rod is used the average thickness of the rod would be: $t_r = .008 d \sqrt{P_m}$, where P_m is the maximum pressure on the rod and D is the cylinder diameter. The cylinder is fastened to the crankcase by flanges and bolted, the joints either being provided with a paper gasket or ground. For an engine of this size the width of the holding flanges would be 2 1-2 inches and three-eighths of an inch thick. The piston length is 1.2 d, where d is the cylinder diameter. The maximum pressure on the piston head would not exceed 240 pounds to the square inch. The formula for the thickness of the piston head would be: $T = r\sqrt{\frac{5}{6} \cdot \frac{P_m}{F}}$ for flat heads, where r is the active radius in inches, T the thickness in inches, P_m the maximum pressure in pounds to the square inch and F is the working stress in the metal and can be taken as 4,200 pounds per square inch.

The weight may be found by estimating the material in the piston and multiplying it by the weight of cast iron which is .260 pounds per cubic inch.

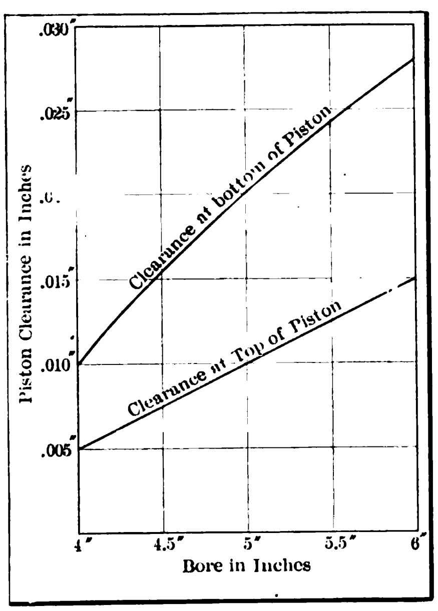

Fig. 1—Curves of piston clearance, showing the correct amount at top and bottom

Announcement

MY 1912 AUTOMOBILE

So much interest is being taken in the coming 1912 models that criticisms are already being heard to the effect that the 1912 automobile is not meeting the expectations of many readers of THE AUTOMOBILE. *In order to discover exactly what are the conceptions of the many readers on the 1912 machines* THE AUTOMOBILE *started last week a discussion on the 1912 models and hereby invites every reader to mail in what are his or her conceptions of next year's car. The information given should include such points as:*

Horsepower	*Tire sizes*
Bore	*Rear axle*
Stroke	*Front axle*
Ignition	*Control parts*
Lubrication	*Body features*
Carburetion	*Equipment*
Clutch	*Cylinder type*
Gearset	*No. of cylinders*
Drive	*Cylinders, how cast*
Springs	*Price*
Wheelbase	

In addition to giving these details the reasons for your points of selection should be stated concisely and clearly.

As a benefit in the matter of comparison some details of the average cars for 1911 are given herewith, these details being for cars selling at $1,000 or thereabouts; $1,500 or thereabouts; $2,500 or therabouts, and $4,000, thereabouts and up.

Each communication must be legibly written on one side of the paper only; it must be properly signed with the writer's full name and address, and if the writer does not wish his own name to appear in print he may request the use of any nom de plume.

Any reader desiring to make line drawings, showing details of his ideas of his car or some of its parts, is requested to do so.

Editor THE AUTOMOBILE.

Proper Piston Clearance

Editor THE AUTOMOBILE:

[2,799]—I am desirous of having a new cylinder made for my car which is not being made any longer the manufacturers having given up the business, I would like to know the correct clearance to allow between the piston and the cylinder. Should the clearance be the same at the top and bottom? A. F. D.

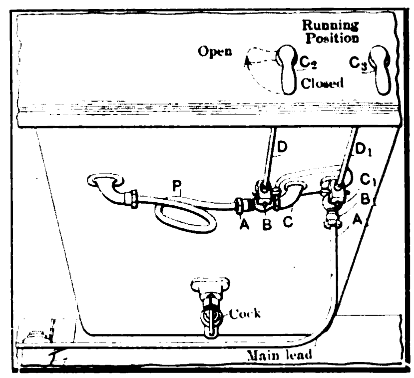

Fig. 2—Illustrating the fittings placed under a gasoline tank

Pekin, Ill.

The clearance should be different at the top and bottom of the piston. As you neglected to mention the bore and stroke of the engine it is impossible to give you figures. A diagram is given herewith, Fig. 1, which will, it is hoped, prove satisfactory in your case as well as in any other of the kind, as it shows the correct clearance for an engine of any bore up to 6 inches.

Wants Varied Information

Editor The Automobile:

[2,800]—Being a subscriber to your valued paper, I would like to ask the following questions:

(1) In a motor of 70 pounds compression, assuming that combustion is perfect, what is the temperature of the mixture at the instant of explosion?

(2) What is meant when a motor is said to have a compression of 50 pounds absolute?

(3) What would be the temperature of a perfect mixture of gasoline and air burned under a pressure of 110 pounds per square inch?

(4) Assuming conditions of question 3, what would be the temperature of kerosene and air?

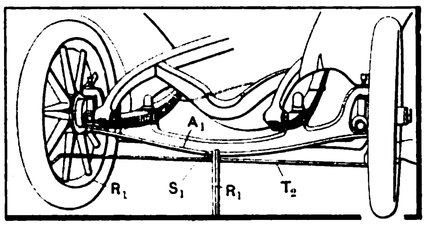

Fig. 3—Illustrating method of determining parallelism of the wheels

(5) What is the chemical composition of kerosene?

(6) In your article on cooling and efficiency in issue of August 3 you mention a two-cycle engine. Could you explain the operation of this motor? G. W. R.

South Auburn, Neb.

(1) Since the specific heat of gases varies as the temperature increases it is not possible to accurately determine the temperature of combustion in the cylinder on this basis even though the calorific value of the fuel be known.

(2) Absolute pressure is pressure above zero, while gauge pressure is that above atmosphere.

(3) and (4) are answered under (1).

(5) Kerosene is a mixture of hydrocarbons chiefly of the methane series. Methane gases are of the form of C_nH_{2n+2} as C_4H_{10}.

(6) We have no full description on hand at present of the motor to which you refer.

Wheels Not Parallel

Editor The Automobile:

[2,801]—Would you kindly tell me a method of testing the wheels of a car to determine whether they are parallel? The front tires on my car wear at such a rapid rate that I am inclined to believe there is something wrong in their alignment. M. G. H.

Albany, N. Y.

The accompanying sketch, Fig. 3, will give a method of testing the wheels. A tubular pointer T_2 with an indicator on either end is used. This pointer consists of two parts, one smaller than the other, so that it may be slid inside and held in any position by the lock nut in the center S_1. A rule R is set up, and the height measured along the tube so that it is parallel. The tube is held in position and is adjusted so that it is parallel to the ground. The method of determining the parallelism is to find the distance between the outer edges of the rim at the front at a given height say 10 inches from the ground and after locking the gauge the same should be placed at the rim at the rear of the wheel at the same height as at the front. There should be a slight toeing in towards the front dependant upon the size of the wheel.

Lifting a Motor

Editor The Automobile:

[2,802]—I have a small garage where I do a great deal of repair work on all types of engines. Would you kindly describe a rig for lifting all types of motors? L. K. L.

Trenton, N. J.

A block and fall could be set on the overhead beams from which an arrangement consisting of a center bar with four drop arms as shown in Fig. 4 which can be used on any type of motor to either lift it out of the chassis or hold it suspended while work is being done.

Condemns Improper Material

Editor The Automobile:

[2,803]—The following analyses of a gear wheel which was put into a car now

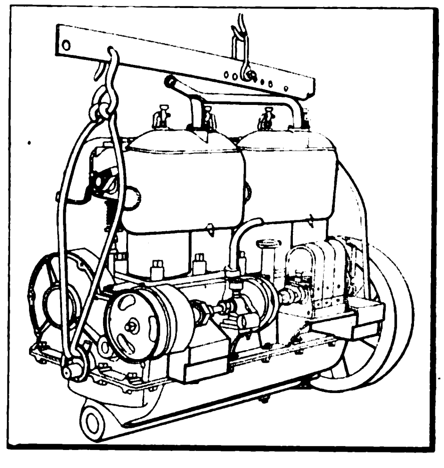

Fig. 4—Showing a device for lifting the motor from the frame and carrying it to another part of the shop

listed for $1,700 may be of interest to your readers as an example of what *not* to buy for this purpose:

Sulphur, 0.056 per cent.
Phosphorus, 0.115 per cent.
Manganese, 0.56 per cent.
Carbon, 0.12 per cent.
Oxides and slag, 0.65 per cent.

This is evidently a poor grade of soft Bessemer steel and was case-hardened. The steel was so laminated as to look at first glance like a poor grade of wrought iron. The gear teeth broke, causing considerable damage. The ignorance or carelessness of anyone using steel like this is hard to understand. F. N. Speller.

Pittsburgh, Pa.

Gasoline Tank Piping

Editor The Automobile:

[2,804]—Would you kindly tell me what pipe fittings it is necessary to buy in installing a gasoline tank for an automobile. I intend to do the work myself and would appreciate any help. J. E. S.

The accompanying Fig. 2 will show a tank tilted which can be made with two compartments, be placed in communication by the pipe P1 and the lever C2 which operates the cock B. The lever C3 placed alongside the lever C2 controls the main flow and should be down when open.

DETAILS OF AVERAGE 1911 CARS WHICH WILL ENABLE READERS TO MAKE COMPARISONS IN DISCUSSING 1912 MODELS

	$1,000 and thereabouts	*$1,500 and thereabouts*	*$2,500 and thereabouts*	*$4,000 and thereabouts*

Little Bits of Motor Wisdom

Pertinent Pointers for Repairman and Driver

A series of short stories that will tend to keep the automobilist in touch with matters mechanical and otherwise, covering a field of information that although usually well tilled, needs frequent and careful cultivation to produce the greatest results.

ATTENTION SHOULD BE PAID TO BRAKE SHOES—Very often the cause of a mysterious rattle will be located in the brake shoes which have worked loose owing to an irregular wear, which has set up unbalanced strains in the drum and given rise to the chatter which is peculiar to this trouble. There are generally two complete sets of brakes carried in the later models of nearly all cars. An illustration of the way these two sets are set up on a single drum is given in Fig. 1, in which a set of expanding and contracting brakes is shown. The contracting or band brake is operated by the bell-crank lever which tightens the band so that a braking effect is attained around a large part of the periphery of the drum. In the internal expanding brake, in a hollow drum which is continually revolving with the wheel or some other revolving part of the car's mechanism there are two metallic shoes which are capable of being pressed firmly against the inner surface of the drum by means of a cam or toggle joint. The advantages of the latter type of brake are that it is less liable to remain set against the drum after the operator's pedal or lever has been released. It is also very easily adapted to either a forward or reverse motion of the wheels and will give a greater braking effect for a given pressure on the braking mechanism. One of the greatest of all its advantages however, is the fact that it can readily be made mud or grit-tight and prevents the parts from rusting.

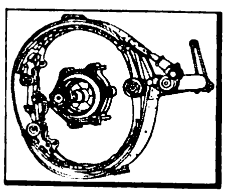

Fig. 1—Form of internal and external brakes used on modern cars

Besides metal to metal contacts the shoes are sometimes covered with an asbestos woven fabric riveted to the surfaces and known as a liner. These liners are readily removable and are less likely to burn out than the metal to metal type. The shoes are sometimes fitted with cork inserts which increase the coefficient of friction and thereby the braking powers.

To provide a surface which will stand both the heat and the wear has been the ambition of those interested in the manufacture of brakes and they have developed a form of reinforced asbestos.

FILLED THROUGH SUPPORTING ARM—A practice which has been affected by various people is to have the crankcase oil filler hole placed in the supporting arm. In this way a large opening may be had, a feature which the breather pipes very often lack. In case the filler opening on the car is smaller than desired by the owner and he finds it impossible to fill the crankcase without great waste and consequent uncleanliness it is often possible to have an opening placed as shown in Fig. 2.

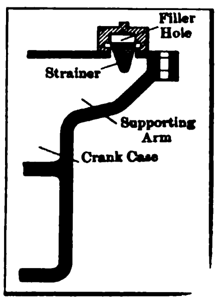

Fig. 2 — Position of filler hole when placed in the crankcase supporting arm

THE PRIMING CUP HAS ITS USES—A fitting which is placed on the top of the cylinder and which has a variety of uses is the priming cup. They are made in divers styles and sizes with a standard pipe thread by which they are connected to the cylinder. The type illustrated in Fig. 3, with a small cup on the top of the compression cock, is very satisfactory, especially since it is protected well against leakage by means of a spring which holds the valve plug in place. When starting the car after it has been cold for a length of time it may sometimes be found necessary to prime the motor. The small cup on the top of the cock forms a measure which can be filled while the cock is closed. The valve is opened by lifting the handle so that it stands upright. The cock will not jar loose while the car is running as the handle is weighted, so that the tendency will be that the handle becomes tighter as the jar continues.

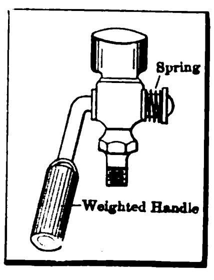

Fig. 3 — Compression cock and priming cock combined in which a spring and weighted handle tend to keep the valve tight under all conditions

SPLASH SYSTEM MUST BE WELL DESIGNED—In arranging a splash system it must not be assumed that the car is always going to run on level ground. The oil, like all other fluids, has a great aptitude of flowing down hill so that when the oil pan is tilted, unless there is some arrangement to hold the oil in position, it will all collect at one end of the crank case and while the cylinders at that end will be fairly drowned in oil the others will suffer a great want of the same important liquid. Fig 4 shows a longitudinal section through a crankcase in which the splash system of oiling is used. It is easily seen that if some means of prevention is not incorporated in the system the oil will run to one end of the crankcase and collect there until the small drainage pipes can drain it off into the reservoir below. In Fig. 5, the narrow splash trough which is often used as a means of overcoming the tendency is shown, the object being, as the diagrams show, to keep the oil in such a position that the connecting rod cap will reach it at whatever level the car happens to be running at the time.

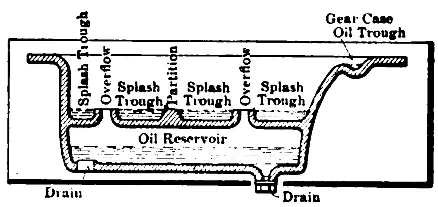

Fig. 4—Longitudinal section through a crankcase in which the splash system is used

Another means adopted in a large number of cars which are lubricated by the splash system is to incorporate a number of slanting troughs along the walls of the splash chambers. These troughs are so arranged that the oil is continually being thrown into them by the connecting rods. They lead the oil back to the next trough where it is picked up and thrown into the trough which carries the oil back into the next chamber and so on until it has reached the last of the series, whereupon the oil is caught in a duct which leads it back to the first trough. The leads on the walls are sloped so severely that it would be impossible for the oil to be led back in the opposite direction on account of descending any hill no matter how steep the same may be. Besides the set of troughs in the walls there are also a series of overflows which take the oil back to the reservoir which is located in the lower part of the crankcase below the tray which carries the splash troughs. These overflows are necessary since the supply of oil is continually being augmented by that which is forced into the oil pan by the pump.

Another method of keeping the oil from collecting in any particular section of the crankcase where the splash system is used is the simple one of providing very large overflow holes and a rapid circulation. If the overflow holes were large without the rapid circulation the oil would overflow down into the reservoir and would not be replaced rapidly enough to fill all the splash troughs. With a rapid circulation the oil is either generally led into the foremost compartment and then allowed to find its way back over the walls into each successive trough, or it is led into each separate trough by tapping for leads into the main oil carrier pipe which will run the entire length of the crankcase.

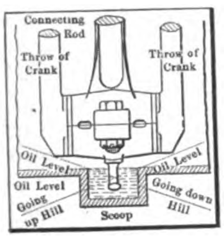

Fig. 5—Small splash trough. This cut shows the influence of road level on the oil in the trough

The greatest care will be necessary in not having a flooded condition of one part of the crankcase when the system is not circulating but the oil is carried in a separate tank which is just drawn upon sufficiently to replace the oil which has been used. In this case the system is generally a combination of both the force feed and splash systems, the oil being led to the main bearings and allowed to lubricate these copiously before flowing into the crankcase to form the splash system. The partitions between the different troughs in this case are most often pierced by a small hole which will keep a constant level under general conditions and which, in case of a hill, will not allow the oil to flow from one compartment to the other rapidly enough to cause smoking trouble.

Levers Are of Different Types—It has been said, with more or less truth, that every mechanical device can be resolved down so that in its primitive or elemental form it will be some variation of the lever or inclined plane. The ordinary wheel in spite of its dissimilarity to the common or garden variety of crowbar is still nothing more or less than a series of these bars which in this case go by the name of spokes; bound together by a rim. The fulcrum in this case being the road, the weight is applied at the axle and the power at various places according to the manner of drive and purpose for which the vehicle is intended.

In any lever there are several things which determine the class to which it belongs; they are the position of the fulcrum or point about which the weight is rotated, the location of the weight and the power which moves it as well as the relative positions of all three. There are three different classes of lever which are generally called first, second and third. The first class, shown in Fig. 6, has the fulcrum between the weight and the power, the second, Fig. 7, has the weight between the power and the fulcrum, while the third, Fig. 8, is that in which the power is applied between the fulcrum and the weight.

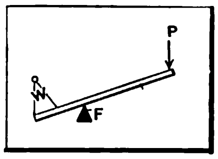

Fig. 6—Illustrating a lever of the first class

The primary and most important purpose of the lever was to apply a greater lifting force to a body than was exerted by the operator of the appliance. It is not to be supposed that there was any gain in total energy, as that would be impossible, but where the gain was made in force applied there was a loss in space traversed, so that aside from the losses by friction in the bearing the number of foot-pounds applied on the power end of the lever is equal to that applied on the weight end. Secondary uses of the lever have been to reduce motion or to change its direction.

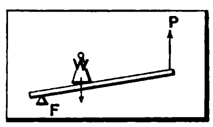

Fig. 7—Typical lever of the second class

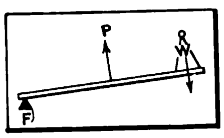

Fig. 8—Lever of the third class, showing relative position of power and weight

The bell crank lever is used in an almost countless number of ways and combines the purpose of changing the direction of the force with that of reducing the motion. It is in general a lever of the first class as may be seen from Fig. 9, which shows the most common form of this useful device. Referring to this figure, if a force P is applied at one end of the lever in a direction as shown by the arrow which passes through the point of application, and it is desired to convert this force into a force P′ acting in the direction indicated by the arrow passing through the other point of application as shown, the two forces will vary inversely as the perpendicular distances between the fulcrum and their line of direction, so that $P : P' :: b : a$.

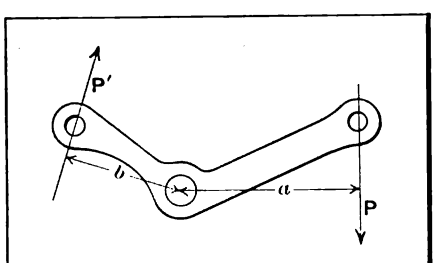

Fig. 9—Bell crank lever showing the direction of the forces P and P′ and their respective lever arms, a and b

In this way any desired reduction or change in direction may be effected. The amount of force necessary to lift a given weight in any lever, irrespective of the class to which it belongs, may be found by this proportion, which well illustrates the well-known fact that the longer the lever the greater the force which can be exerted on the weight, provided that the weight is relatively near to the fulcrum.

A Well-Known Kink—Apropos of the subject of levers and the great gain in applied force by the use of a long arm, the well-known kink of increasing the turning power of wrench by slipping a piece of pipe over it may naturally occur to one. In a small bolt where this principle is employed care should be taken that the nut is not stripped by a too violent pull on the part of an over-enthusiastic operator. The accompanying sketch, Fig. 10, gives an idea of the relative length of pipe to spanner for very effective work.

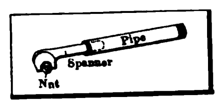

Fig. 10—Placing a pipe over a spanner to obtain greater turning moment

---

When Gravity Feed Is Used—In case of a pipe leak of gasoline, which has to be repaired on the road, it is a very uncomfortable feeling which creeps over the driver who has no means of shutting off the gasoline near the tank. A valve should be inserted in the very beginning of the line from tank to carbureter bowl and may be located as shown in Fig. 11. If this valve is inserted at the end of the tank it affords an excellent opportunity to place a screen over the opening so that there is plenty of precaution against foreign matter which might have found its way past the filler opening, especially since there are many drivers who regard the straining of gasoline as it is placed into the tank as a waste of valuable time.

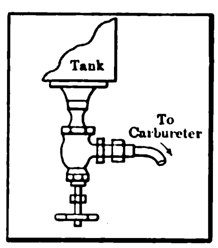

Fig. 11 — Position of valve below gasoline tank.

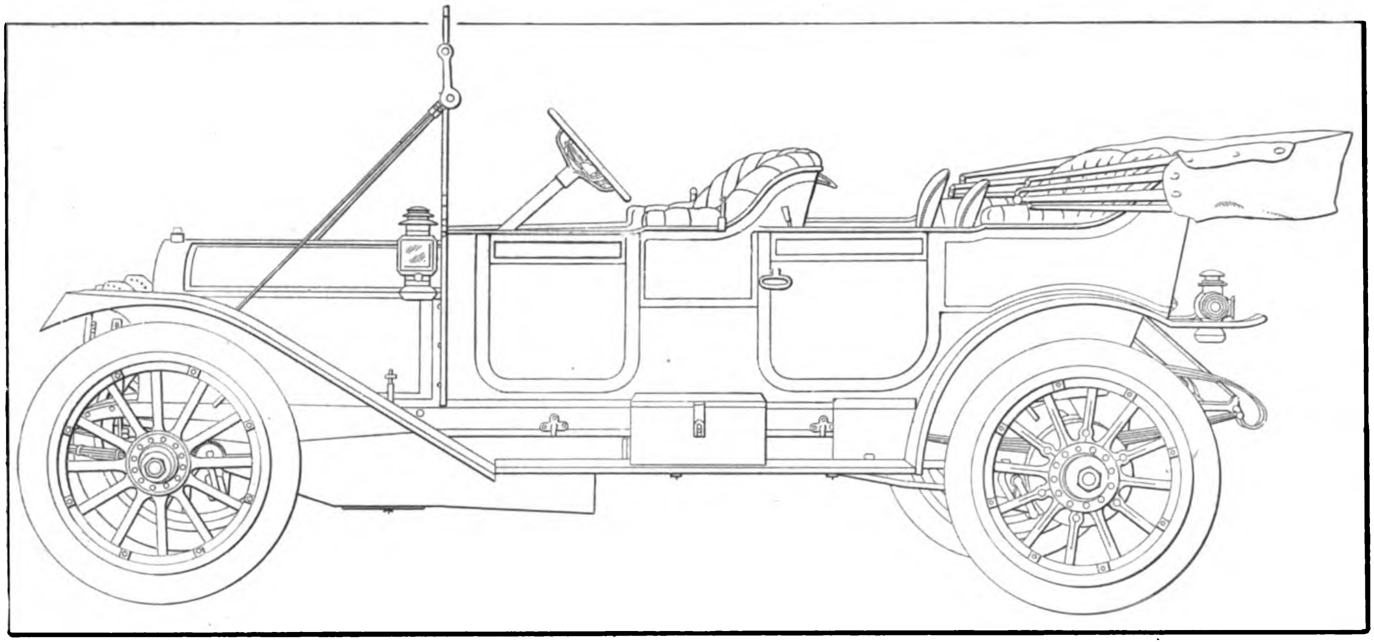

Fig. 1—Side view of the 40-horsepower, seven-passenger, fore-door Corbin touring car, presenting general appearance

Pertinent Details of the Corbin

Characterized by Insignificant Changes

Whether the automobile has arrived at any degree of finality is a matter that will be left to historians at some later date; but an outstanding feature in the coming season's model of quite a large proportion of the manufacturers of this country shows a decided trend to adhere to the general scheme adopted last year, with whatever improvements and alterations that may have been found necessary or desirable in the light of the year's experience.

THE preceding remarks may be applied to the product of the Corbin Motor Vehicle Corporation, of New Britain, Conn., manufacturers of the Corbin car. This concern is offering to buyers two models of 40 and 30 horsepower respectively, with six styles of bodywork. In order to differentiate between the two models it is proposed to handle each one separately, so as not to confuse the buyer.

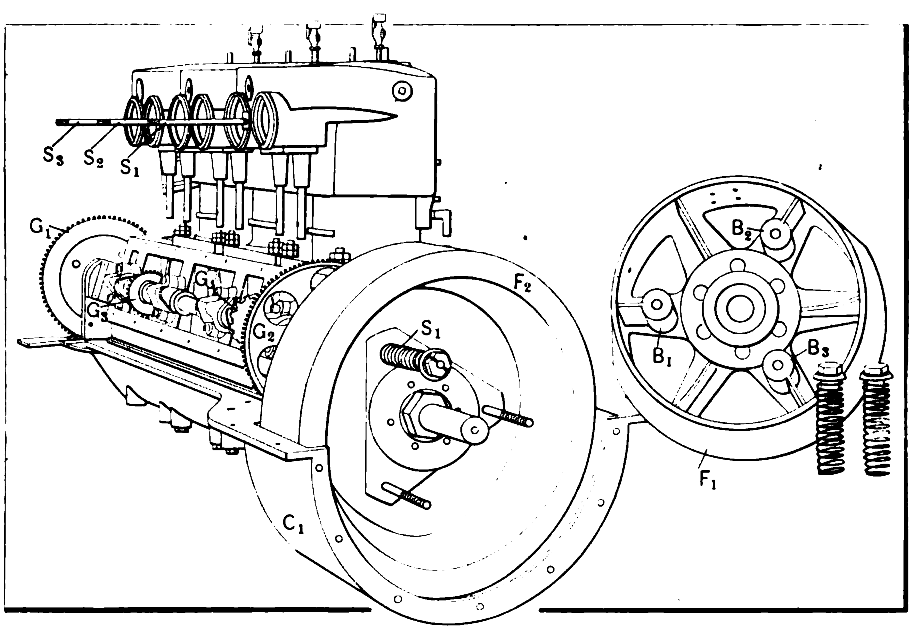

Fig. 2—Showing the 30-horsepower Corbin motor, with the clutch disassembled and valve gear cover removed

The 40-horsepower model has a four-cylinder motor, with the cylinders cast in pairs, having a bore of 4.75 inches and a piston travel of 5.5 inches. The cylinders are cast from a special gray iron, with integral waterjackets, and are afterward carefully ground to size. The valves are nickel steel, 2.5 inches in diameter, and as the cylinders have T-heads, the former being placed on opposite sides of the motor. The pistons are gray iron and are 6.25 inches long. A large oil groove is machined on the wrist pins, which are made from alloy steel, hardened and ground, being 1.25 inches in diameter. The upper ends of the connecting rods are clamped to the wristpins which oscillate in the piston bosses. The pistons are fitted with four eccentric rings, 1-4 inch wide and provided with diagonal-cut slots. The connecting rods are drop-forgings, of I-section, the big-end bearings being 3.5 inches long.

Fig. 3 shows the lower half of the base chamber with the bottom cover removed, from which can be seen the method of supporting the crankshaft. Three main bearings are employed, the journals of which are 2 inches in diameter, and all bearings are finished by grinding. Front and center boxes C and C2 are 3.5 inches long, while the bearing next to the flywheel is 4.5 inches in length. The crankshaft is an alloy-steel forging with an offset from the perpendicular axis of the cylinders of 1 inch, in order to reduce the angularity of the connecting rods, thereby decreasing the piston thrust on the cylinder walls. The camshaft of the 40-horsepower motor is 15-16 inch in diameter, and runs on three bronze bearings, the front being 3.25 inches long at the point where the strain is greatest, due to the gearing, the center and rear bushings being 2.25 and 2.5 inches in length respectively. The method of driving the camshaft can be seen by referring to Fig. 3, but in this illustration the camshafts, together with their gears, have been removed. The gears utilized for driving the camshafts, pump and magneto shafts are cut with helical teeth from steel blanks.

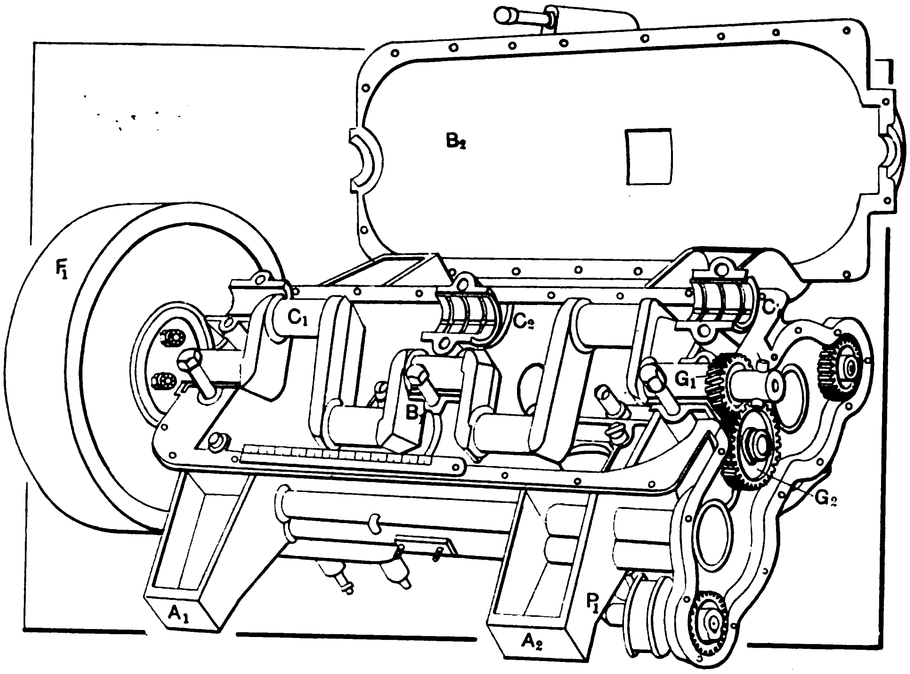

Fig. 3—Looking into the crankcase of the "40" model, with the lower half of the case removed, illustrating crankshaft construction and bearings

Fig. 3 shows the method employed of supporting the motor by four arms cast integral with the top half of the crankcase. The lower half of the crankcase can be removed without disturbing the crankshaft bearings and forms a container for the lubricating oil. The oiling system is of the constant circulation type, the lubricant being kept in motion by a gear pump, driven by bevel gears from the exhaust camshaft. A conduit is cored in the sidewall of the upper half of the crankcase, which forms the supply for the main bearings. The surplus oil reaches the crankpins through passageways in the shaft, while a spray or mist thrown by the rapidly revolving crankshaft lubricates the cylinders and other internal parts. It will be noticed that in the base B2 of Fig. 3 there is a square hole, through which the excess oil drains to the lower sump, no lubricant remaining in the case for the connecting rods to dip into.

The motor is cooled by means of a water-circulation system, employing a gear pump driven direct by an intermediary gear wheel off the halftime shaft. The water leaves the bottom of a honeycomb-type radiator and is forced by the pump to the water spaces surrounding the exhaust valve cages, and thence through the water spaces around the cylinders. The manifolds are well proportioned, the rear portion of the outlet pipe having a bore of 1.125 inches. The cylinder heads have a one-piece cover, secured in position by means of suitable packing and eight studs, and from each of these is led a single pipe. The size of the return flow pipe at the point where the front cylinders discharge their water is increased to 1.5 inches to compensate for the increased flow of water. The manifolds are of brazed construction, of copper piping, and the unions are either ground or fitted with packing flanges. The pump shaft bearing, which carries the stuffing box at the outer end, is 4 inches long, and interposed between the gearing and the pump, attached to the extension of the shaft there is a pulley which serves to drive the six-bladed fan which is mounted on a sliding bracket, driven through the instrumentality of a 1-inch wide, endless, flat belt, the tension of which is maintained uniform at all times.

The ignition is furnished by a U. & H. magneto which rests upon the front supporting arm of the motor, on the intake side. An entirely independent and supplementary ignition is fur-

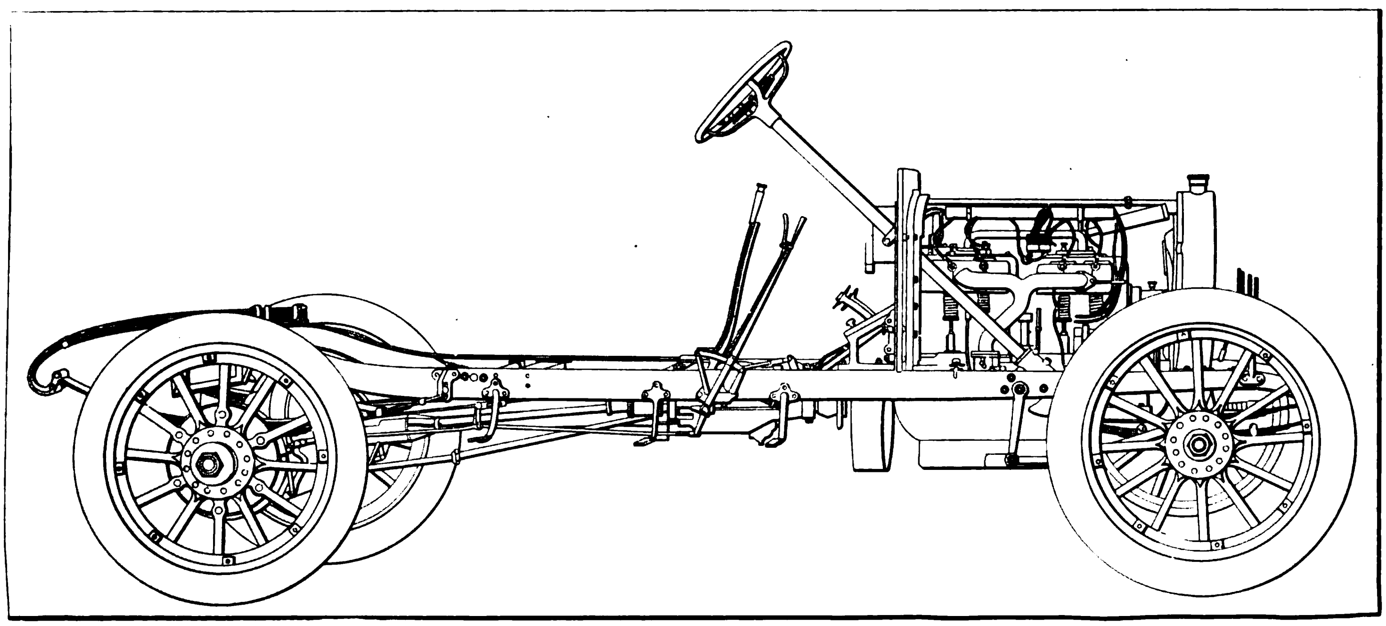

Fig. 4—Chassis of the 40-horsepower Corbin, showing the intake side of motor, steering equipment and substantial design of transmission and suspension

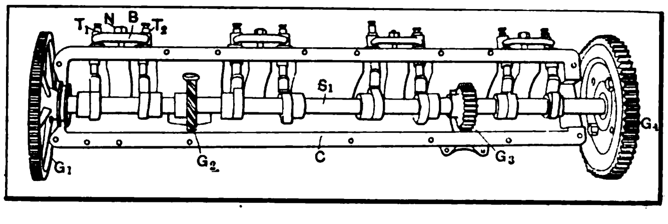

Fig. 5—Camshaft assembly of the 30-horsepower Corbin motor, illustrating the manner of actuating the valves

nished by means of a distributor, in conjunction with batteries and a single-unit coil. The distributor is located between the cylinders on the intake side and is driven by a vertical shaft through bevel gearing off the intake camshaft. A bracket is attached to the rear end of the front pair of cylinders to form a support for the vertical shaft at its upper extremity, and a grease cup is provided to maintain proper lubrication of this part.

The flywheel, which is bolted to the flange on the end of the crankshaft, is 17.5 inches in diameter, and has a female member of the cone clutch machined in the inner periphery of the rim, which is 4.375 inches wide. The clutch is of the cone type, with three separate springs, which transmits the power from the motor to a three-speed gearbox, the shafts being placed horizontally and are carried on annular type ball bearings. The rear axle is of the full-floating type, the main housing is composed of two substantial, pressed-steel members, welded together at the top and bottom by the autogenous process. The differential and driving gearing are supported by a steel casting, and are always maintained in proper relation to each other. The differential with its bevel gear is adjustable with reference to the pinion, and the pinion is also adjustable by a locking collar in front of the pinion bearing, which insures proper meshing of the gears. The propeller shaft connecting the transmission and the differential has two universal joints, and the torque of the rear axle is taken care of by a V-formed torsion bar terminating at its forward end in a spring damper attached to a cross member of the frame. The rear end spans the differential housing and provision is made for an oblique hinge movement.

Two sets of brakes are provided, acting respectively upon the interior and exterior of the brake drums attached to the rear driving wheels. The wheelbase of the 40-horsepower model is 120 inches long, and the thread is standard, 56 inches. The suspension of the pressed-steel chassis, which is narrowed in front, is taken care of by semi-elliptic springs at the forward end, three-quarter-elliptic springs being used at the rear, the back end of the frame having a slight pick-up to adequately take care of this style of suspension.

The Corbin 30-horsepower differs from the larger type in so far that the cylinders are cast with L-shaped heads, the valves being placed side by side and operated from a common camshaft. The bore of the 30-horsepower model is 4.5 inches, while the stroke is slightly less, being 4.25 inches.

The valve lifters are in bronze guides, which can be easily removed, as they are attached to the camshaft housing by double stirrup fittings, held in place by one bolt. The valves are of the nickel steel, head and stem being formed integral. The valve springs instead of being the conventional form are coned at the lower ends and deliver their pressure against a large splitpin passed through the valve stem, no collars or keys being employed. The raising effort of the cam is not taken directly by the plunger, but upon the lower end of the lever interposed between it and the cam. The plungers are fitted with hardened set screws having check nut retention, so that the clearance between them and the valve stems may be accurately maintained.

The entire camshaft assembly is housed in a separate case which forms a unit that can be separately assembled and applied to the side of the motor base, as shown in Fig. 5. The pistons have four rings and two oil grooves. The wristpin is a hollow piece of special steel with hardened surfaces. This is machined on a slight taper and formed in the piston bosses, where it is retained by a set screw with a pin at the end projecting in the interior.

The connecting rods are forgings of special steel and have hinged lower caps, affording adjustment by tightening one bolt. By removing large plates at the side of the case, these are easily reached for either inspection or adjustment. The upper ends of the connecting rods are bushed with bronze, the lower ends have bearings of white metal.

The cylinders are mounted on an aluminum member, which forms the upper member of a two-part crankcase, surmounting an oil basin of the same material with dual oil pits. The crankshaft bearings are not in the upper half, but in the oil basin, the top portion merely supplying caps for the ball bearings carrying the crankshaft at the outer journals. The lower crankcase member has three intermediate bearings, bushed with white brass, which suport the inner three of the five shaft journals.

The oil basin and motor basin are held to the cylinder lugs by long through bolts, the heads being under the oil basin, the nuts on the top of the cylinder base flange. The rear end of the lower half of the engine base spreads to form a shield for the flywheel and clutch, and as the gearset casing is similarly formed at the forward end, it is bolted to the flywheel shield and a unit power plant construction obtained. The front end of the motor assembly is supported by an I-section steel cross-member. Steel plates attached to the chassis frame side-members and extending to the crankshaft not only act as a brace and support of considerable length, but serve to enclose the whole front portion of the chassis.

Lubrication is by a special pump system, the oil supply being carried in a tank above the flywheel. A sliding valve pumps into this supply and forces it through leads to the four cylinders. Splash wells are provided in the crankcase, which are filled by other leads leading from the tank. The three central bearings are fitted with caps, which receive the oil that is splashed up by the connecting rod ends, thereby feeding the main bearings. The clutch and gearbox on this model are almost identical with the 40-horsepower model, but a difference is made in the rear axle which is of the fixed type. The wheelbase is 115 inches. The price of the 40-horsepower model is $3,000 and the 30-horsepower, $2,000.

Selecting an Automobile

When the average man has decided to buy an automobile after a long and careful consideration of the expense involved and the return either in business or pleasure to be had from the same he generally becomes the victim of not only the ever-alert salesman but also of his best and dearest friends.

TO the man of moderate means the purchase of an automobile is, like breaking out of jail, a thing not to be lightly undertaken. After a careful consideration of the greatest amount of money which can be invested, he looks about in the manner of all sensible men for the greatest possible value to be obtained for the money. If he is the possessor of friends who own automobiles he invites their opinion and advice as well as that of the sales agents of the concerns who furnish a car at the desired price.

The advice of his friends is apt to be biased, as it is gained from one-sided experience, while the advice of the salesmen, although perhaps the result of much experience, is hardly less biased. A demonstration may prove much and it may prove very little, so the prospective automobilist does not know which way to turn. The wise man, however, buys a car of good repute with a solid guarantee, or in the case of a car unknown, has it thoroughly examined by a competent judge.

The style of body purchased will, to a large degree, determine whether the automobilist will be satisfied or disappointed after he has had the machine for a length of time. It is in this feature that the purchaser may rely upon the company from whom he is buying the car, as the great experience of the dealer will aid his judgment in this respect.

As to the Merits of Vanadium

Further Pertinent Discussion on the Subject

In the issue of "The Automobile" of July 27 the criticisms of George L. Norris appeared in reply to an article from the pen of E. F. Lake upon the subject of alloy steels, and incidentally Vanadium, together with E. F. Lake's reply. Mr. Norris again replies to Mr. Lake, quoting chapter and verse, and an opportunity has been given to Mr. Lake to reply.

George L. Norris Criticises E. F. Lake's Position

MR. LAKE'S reply to my letter in which I take exception to his statements relative to vanadium opens that I state the article in question "is worthless." I did not make such a statement.

The reason why tests or data to illustrate the beneficial effect of vanadium as a constituent of the steel were not given was simply because it was not considered necessary in view of the great prominence attained by vanadium steels during the past eight or nine years, and the many treatises and articles containing such tests that have been published. The inference that they could not be produced is unwarranted, as previous articles by Mr. Lake and also the 1911 edition of his book on "Composition and Heat Treatment of Steel" prove that he has seen many of these and accepted them as showing that vanadium does add of itself virtues to steel. It would be a pleasure to submit not only the already published tests and opinions of metallurgists of international and local reputation, but also a large amount of unpublished material. I would say that a careful search of the literature of steel fails to reveal any of the countless tests mentioned by Mr. Lake in which vanadium steels failed to nearly approach chrome-nickel steels in static or dynamic qualities.

I know of no metallurgist or steel maker who has investigated or made vanadium steel who has gone on record that "the main mission of vanadium is as a scavenger." Among the investigators are such eminent metallurgists as Arnold, Guillet, Putz, Harbord, Longmuir, Law, Mathews, J. Kent Smith and others. With the exception of J. Kent Smith none of those mentioned refers to or lays any stress on the action of vanadium as a scavenger. This is remarkable when we consider the great amount of work done by such thorough, painstaking and acute observers as Arnold and Guillet, not to mention the others.

J. Kent Smith was undoubtedly the originator of the statement that vanadium is a powerful scavenger, but he never in public discussions made any such statement. Neither have I, as his successor, made any such statement. The literature of our company distinctly states that vanadium exerts its power in at least three ways, one of which is scavenging. It also distinctly states that an extra amount of vanadium must be added for this very purpose. Mr. Lake has this literature and I do not see how he can even carelessly read it otherwise.

How Professor Arnold's positive statement, "Vanadium is *undoubtedly* the element which, together with carbon, acts with the greatest intensity in the way of improving the iron," can be said to be qualified with a word of doubt is beyond comprehension. Neither is Professor Arnold's expression of opinion of the way vanadium acts or exercises its influence qualified. It is a simple, straightforward statement, or opinion, based on experimental facts available at the time, and never since modified by Professor Arnold in any additional contributions he has made to the literature of vanadium steels. Harbord, in his "Metallurgy of Steels," accepts Professor Arnold's conclusions and uses them without any of the qualifying explanations suggested by Mr. Lake. The statements regarding vanadium steels in Mr. Lake's book, 1911 edition, revised and corrected, and in previous articles by him on vanadium steels are completely at variance with his statements in his article of June 29 and his reply in THE AUTOMOBILE of July 27. I am at a loss to understand the remarkable change in Mr. Lake's opinion of vanadium as shown by the following statements:

AUTOMOBILE, *June* 29, 1911.

"Vanadium of itself adds no virtues to steel. When it has cleansed the steel of impurities it has performed its mission; thus, it is as well to allow it to go off into the slag as to try to keep any in the steel.

"Of the vanadium steels very little, if any, vanadium is present in the finished product, and hence vanadium steel is a misnomer."

AUTOMOBILE, *July 27*, 1911.

"Vanadium of itself adds no virtues to steel. In trying to refute this statement, he (Mr. Norris) says, 'The experience of a large number of steel manufacturers is overwhelmingly opposed to this statement—it is a question of having the vanadium in the steel because by countless tests it has been proved that vanadium produces definite beneficial results. Why has he not submitted one of these?' This element (titanium) will give practically the same results that are obtained with vanadium, and its growing competition may be the cause for the claims that vanadium of itself, in the proper percentages, adds to the static and dynamic properties of steel."

AUTOMOBILE, *July 27*, 1911.

"Countless tests have been made with vanadium-treated steels in comparison with other steels, but not one of these tests has shown us that vanadium-treated steels equal either the static or dynamic properties of chrome-nickel steel; in most cases they could not nearly approach it."

AUTOMOBILE, *July 27*, 1911.

"The mere statement that a large number of steel manufacturers are producing vanadium steels regularly proves nothing *except that they are supplying a demand.*"

AUTOMOBILE, *July 27*, 1911.

"Neither in my original article nor in this answer to Mr. Norris have I said that vanadium did not produce beneficial results when properly *alloyed* and used in the correct proportions.

"Composition and Heat-Treatment of Steel,"
1911, *page* 104.

"Vanadium has made great strides in the past few years as an *alloying* element, and is used in steel castings, cast iron, and the bronzes and brasses as well as in steel mill products."

Page 119.

"Vanadium has given such good results in rolled steels that it has been taken up by some of the steel foundries." (Then follows a comparative test very favorable to vanadium.) "Before adding vanadium in the furnace it is necessary to have the oxides all removed from the metal as vanadium has a great affinity for oxygen. If any of the oxides remain in the metal, the vanadium will scavenge them out and go off in the slag; but as vanadium is too expensive to use as a scavenger, the oxides should be removed as completely as possible before it is added to the steel." "Many failures in the use of vanadium in the past have been due to this elusiveness, or its affinity for oxygen, etc. As a matter of fact, it might have completely oxidized out of the metal *and not given it any of the desirable properties of which it is capable.*"

"Vanadium Steel" — Machinery, Oct., 1907.

"While vanadium affects steel in a manner that tends to increase the static strengths of other alloys, it also raises the dynamic properties to an extent that is not thought of in other alloys." (This article also contains numerous tests and illustrations demonstrating the beneficial effects of vanadium when alloyed with chromium, etc.

"Composition and Heat-Treatment of Steels,"
Page 123.

"A chrome vanadium steel will give as great strength as a nickel-chrome and can be forged as easily as a 0.40% carbon steel."

Pages 99 *and* 100.

"When chrome is *combined* with nickel or *vanadium* it makes the strongest, toughest and best wearing steel on the market, etc."

"The nickel-chrome steels are difficult to forge—it must be heated many times to forge pieces of any size of intricate shape." (The demand for vanadium steels is explained by the above.)

The usual loss of vanadium in steelmaking, excepting the electric furnace process, where there is no loss, is from 10 per cent. to 20 per cent. Now, if the steel maker can attain all the benefits possible through the scavenging action of vanadium and only wants to leave it in to prove to the chemist that it was used, why does he leave in three or four times as much as the chemist can readily determine? In protective deckplate where no chemical proof is required—because the Government does not distinctly specify composition, only physical and ballistic tests—I am assured by the manufacturers that they cannot meet the requirements if they use vanadium solely as a scavenger, or do not exceed a certain percentage in the steel. I am assured by other steel makers that such has also been their experience.

In the manufacture of electric furnace steel vanadium does not act as a scavenger, it cannot, owing to the highly reducing conditions in the furnace. If added in the form of vanadium oxide it would be reduced. All the vanadium added to an electric furnace is found in the steel. This I know from my own experience, and also by reports from electric steel makers. There is no reason to expect that because metals are melted or refined in an electric furnace their metallurgical, chemical or physical qualities will be radically changed, in fact, the electric steel makers of to-day are simply claiming equality with crucible steel. I have under way an extensive series of tests covering open-hearth steel, both basic and acid, crucible and electric furnace steels, with and without vanadium, and I can assure Mr. Lake that the electric furnace steels are showing the same relative improvement through the use of vanadium as the steels made by the other processes.

In a lecture before the Franklin Institute, May, 1909, after three years' experience with electric-furnace steelmaking, Dr. John Mathews makes the following statement: "The chrome-vanadium alloys are preferably made in the crucible or *electric* furnace, although the open-hearth process is also much used for the purpose." "By judicious *blending* of chromium and vanadium and adjustment of the manganese and carbon, one can not only obtain all static properties that can be obtained from nickel, chrome-nickel or silico-manganese alloys, but in addition obtain dynamic or anti-fatigue qualities far in excess of those displayed by any other alloys. In general, nickel-chrome steels possess excellent static qualities, but the difficulties in heat-treatment, forging and machining lead one to prefer the other types of alloys previously mentioned." "The number of alternations of stress to produce fracture gives a measure of vitality, so to speak. Average results of a great many tests made in this way of crucible carbon springs, chrome-nickel, silico-manganese and genuine crucible chrome-vanadium springs proves the extraordinary quality of the last-named product. The average figures for alternations were as follows: Crucible carbon spring, 150,000; chrome-nickel and silico-manganese, each 200,-000; chrome-vanadium, 5,000,000 and still unbroken."

Longmuir in May, 1909, presented a paper before the British Iron and Steel Institute on "High-Tension Steels," in which direct comparisons were made with nickel steels, chrome nickel steels and chrome-vanadium steels. It happens that one of the chrome-nickel steels has approximately the same composition as Mr. Lake's ideal steel:

	Longmuir.	Lake.
Carbon	0.30%	.25%
Nickel	5.00%	4.50%
Chromium	1.00%	1.50%

The physical properties of this steel are given in the following table:

NICKEL-CHROMIUM STEELS

No.	Condition.	Elastic limit, tons per sq. in.	Maximum stress, tons per sq. in.	Elongation, per cent on 2 in.	Reduction of area, per cent.
31	Treated, i.e.,		ETAOIN N..N N..		N..N N
32	quenched in	59.63	66.23	16.0	38.6
33	water from 850°	52.42	61.16	18.0	41.6
34	C. to 900° C.,	59.74	64.28	19.5	47.2
35	and tempered at	56.70	63.66	20.0	43.4
36	550° C.	55.08	61.88	21.0	45.4

Compare with this the physical properties given of a chrome-vanadium steel of practically the same carbon: Carbon, 0.32 per cent.; chromium, 1.10 per cent.; vanadium, 0.16 per cent.

TREATED CHROMIUM-VANADIUM STEELS

No.	Test cut from	Elastic limit, tons per sq. in.	Maximum stress, tons per sq. in.	Elongation, per cent on 2 in.	Reduction of area, per cent.
56	1-in. diameter bar	63.48	67.68	17.0	.....
57	Crank	56.44	64.78	15.0	.....
58	Axle	61.34	67.32	17.0	33.6
59	Axle	56.16	63.12	22.0	47.2

Mr. Longmuir's conclusions are: "The work done shows that nickel steels do not give the high values obtained from nickel-chromium, or chrome-vanadium. The last two represent exceptionally good types of high-tension steels, but for all-around properties chrome-vanadium gives the best results."

The above tests practically confirm the statement in Roscoe & Schorlemer's treatise on chemistry, that "vanadium acts in a similar manner to nickel, but is much more efficient, 0.20 per cent. producing the same effect as 3 to 4 per cent. of nickel."

I can assure Mr. Lake that the "growing competition" of titanium as a scavenger is not "the cause for the claims that vanadium of itself, in the proper percentages, adds to the static and dynamic properties of steels." These claims for vanadium have been made from the very beginning by disinterested investigators of high standing.

Mr. Lake Answers Mr. Norris' Second Criticism

The tone of Mr. Norris' second criticism has been considerably changed, and in it some evidence and data are given on which a discussion can be made as to the real merits of the case. To merely say that "the great prominence obtained by vanadium steel during the past eight or nine years was the reason why no tests or data were given" is to dodge the issue. To say "it would be a pleasure to submit not only the already published tests and opinions of metallurgists of international and local reputation but also a large amount of unpublished material" proves nothing, unless more than opinions are submitted. It is a bold assertion when he says, "the inference that they could not be produced is unwarranted" if facts are not produced.

When he says "a careful search of the literature of steel fails to reveal any of the countless tests mentioned by Mr. Lake in which vanadium steels failed to nearly approach chrome-nickel steels in static or dynamic qualities" it might be that none of these had been recorded and brought to his attention. On the other hand, in the large amount of research work I have done since vanadium came into commercial use, I have failed to find any reliable tests where vanadium steels equaled, much less excelled, the physical properties of chrome-nickel steel that was properly made and heat-treated. One or two instances have been given such as Mr. Norris submits in the latter part of his discussion when he says, "The average figures for alterations were as follows: Chrome-carbon spring, 150,000; chrome-nickel and silico manganese, each, 200,-000; chrome-vanadium, 5,000,000 and still unbroken."

These figures would indicate to me that, either a very poor grade or an improperly heat-treated chrome-nickel steel was used when it only showed 200,000 alternations. I have seen chrome-nickel steel withstand 2,250,000 alternations and have heard of other tests that gave better results than this. I have also seen steels tested on the White-Southers rotary vibrational machine in which an open-hearth low carbon steel withstood 2,660,000 revolutions, while steel that was very similar to the vanadium products withstood a little over 25,000,000 revolutions at the same fibre stress. While this comparison was between a low-grade, cheap steel, and a high-grade one, it only made one about ten times greater than the other. In Mr. Norris' comparison, however, it is to be supposed that the chrome-vanadium and chrome-nickel steels are both of the highest grade and properly heat-treated. Therefore, to make one withstand 25 times as many alternations as the other seems beyond reason and unbelievable. Such a difference could not exist unless test bars from the very best grade of chrome-vanadium steel were used to compare with those from a very poor grade of chrome-nickel steel or unless the heat-treatment was such as would make one steel fail long before the other, or both.

Since Roscoe separated the element vanadium in the '60's much experimental work has been done. It is only within the last decade, however, that vanadium has had a commercial application in practical steel making. Of the metallurgists whom Mr. Norris mentions as investigators of vanadium, J. Kent Smith is the only one that has specialized on this subject. The others have spent most of their time working on other steels and have doubtless accepted Mr. Smith's statement that "vanadium is a powerful scavenger." It might be added that this was the only statement that Mr. Smith emphasized. When Mr. Norris says, "I know of no metallurgist or steel maker who has investigated or made vanadium steel, who has gone on record that the main mission of vanadium is as a scavenger," I might say I know of none who have said that the main mission of vanadium is *not* that of a scavenger. After these two seemingly opposite statements have been made, nothing is gained and those selling the alloy might be the only ones to contradict either statement. Even at that they might both be true.

The comparative tests that the makers' literature has given me are all between carbon steel, nickel steel and vanadium steel. In most of these, chrome-vanadium steel has been compared with Government nickel steel, or in other words, the highest type of vanadium steel has been compared with a nickel steel that is not of the highest type. When this fact was presented to J. Kent Smith in July of 1907, he informed me that experiments were being conducted to show the physical and dynamic differences between chrome-nickel and chrome vanadium steel. As four years have elapsed and none of this data has been given out, I am perfectly justified in forming the conclusion that the tests did not show superior results for vanadium. Therefore, I again say that none of the vanadium steels equal the chrome-nickel steels in physical properties.

Mr. Norris says, "I have under way an extensive series of tests covering open-hearth steel, both basic and acid, crucible and electric furnace steels, with and without vanadium; and I can assure Mr. Lake that the electric furnace steels are making the same relative improvement through the use of vanadium as the steels made by the other processes." This again is only a statement without any data or facts being given to prove the assertion and until such data is forthcoming, we have the right to express our doubts.

While we know that great improvements can be made in certain grades of steel by the addition of vanadium, we still hold to the opinion that the high-grade chrome-nickel steels are the superior of vanadium steels. While there have been many exaggerated statements made in regard to vanadium, it is a rare thing for anyone to claim that the vanadium steels equal the chrome-nickel steels in physical properties. Investigations or experiments to prove this are also seldom made. From all the evidence I can gather, well-made vanadium steels are excellent material and probably the chrome-nickel steels are the only ones that excel them. The vanadium steels are much easier to machine than nickel-chrome steel and as they sell for a lower price, they are excellent steels for automobile uses.

It is impossible for one man to investigate all kinds of steels thoroughly or to know everything about steel. Thus the statements of others have to be accepted when they appear to be correct. That there is a great deal of commercialism in the steel business and that many a good metallurgist has had his opinions biased by this commercialism cannot be denied any more than it can be denied that the noted chemist Dr. Wiley encountered troubles when he tried to make the prepared food companies leave poisons out of the foods. To do so meant some loss of profits to the companies and thus an attempt was made to remove him.

From the commercial metallurgists, we are liable to get data, results of tests, etc., that only tell part of the truth. This often misleads others who are earnestly seeking for facts and at times might cause them to make false statements unknowingly. There is so much commercialism in the steel industry that it is very difficult to get at any real facts in regard to data, tests, etc., or any just comparisons of different grades of steel.

Then again, investigations and discoveries are being made every day that upset former theories and opinions that appeared to be facts. No man has yet lived who did not change such opinions when presented with data that disproved them. Because a man said something in the last century, the last decade, last year, last month or even yesterday, it is absolutely correct, is a very false principle on which to establish an argument. This argument, therefore, should be based on what is and not on what has been.

Because I said a certain chrome-nickel steel gave good results, it does not warrant Mr. Norris in branding it "Mr. Lake's ideal steel," as there are many other compositions of chrome-nickel steel that might give as good, if not better, results. The improvements that are continually being made do not make me desirous of calling any particular composition my ideal steel. Then again it is not fair to compare it with Longmuir's steel that contains 1-3 less chromium, 1-9 more nickel and 1-5 more carbon. When this is done, however, it does not show any great difference in their tensile properties and does not attempt to show any difference in their alternations.

While I do not like to bring others into this discussion, Mr. Norris has twice quoted Dr. John A. Matthews. Within one month, either way, from January 1, 1908, I talked with Dr. Matthews in Syracuse, N. Y. At that time he was very much opposed to vanadium and severely criticised some of the statements I had made in regard to it, and which Mr. Norris is now quoting from *Machinery*, October, 1907. There was no electric furnace in the plant with which Dr. Matthews was connected. In May, 1909, he delivered the lecture Mr. Norris mentions. In the Halcomb steel plant, of which Dr. Matthews was then president, an electric steel-making furnace was located. It was one of the first that had been installed in this country and was in very poor condition when he took hold of it, as the former management had made it a failure. Thus instead of three years' experience with electric furnace steel making, as Mr. Norris says, Dr. Matthews had less than half of that at the time he delivered the lecture that Mr. Norris quotes from.

That vanadium produces some very good results when used in steel making cannot be successfully denied. Whether it has completed its mission when it acts as a scavenger or whether it adds, of itself, certain properties to steel, is a much disputed question. That I take the former position is due to the fact that this has been thoroughly demonstrated. The latter position, however, needs a great deal more data to prove the theories advanced and until this data is forthcoming I cannot accept Mr. Norris' theory. In either case, however, it is more of an argument for the metallurgists and steel makers than for the readers of The Automobile. They are more interested in the practical results obtained from the metal than in the eutectic, solid solution, oxidizing, scavenging or other forms or reactions the elements may enter into in the manufacture of the product.

That oxygen, nitrogen and hydrogen are present in steels in larger percentages than have formerly been supposed and that these are as injurious to the metal as phosphorus and more injurious than any of the other elements, has now become well recognized. That these may take the form of occluded gases, or microscopic bubbles, or segregate in quantities sufficient to produce holes large enough to be seen with the naked eye, termed blow-holes, is an undisputed fact. That they unite with other elements and cause these to injure the metal is also fast becoming recognized.

These gases are present in the largest percentages in steels made by the Bessemer process; open-hearth steels are second in the percentage of gases present, with crucible-made steels third, and electric steels fourth. In the electric furnace they can be reduced to very low percentages, owing to the ability to protect the liquid bath from the atmosphere and also to use slags that will keep them out or cause their removal. Steels made with the crucible process are not very high in these gases, as the crucibles are sealed up and thus protected from the outside air.

With any of these processes, unless it be the Bessemer, "vanadium can be properly *alloyed* and used in the correct percentages" to remove the larger part of the gases left after the steel has been refined by other methods, and prove on chemical analysis that it is a vanadium steel. This in no way contradicts my statement in THE AUTOMOBILE of June 29, when I said "vanadium of itself adds no virtues to steel, etc." When thus used the vanadium will greatly increase the static strengths of the metal, bring the elastic limit up close to the tensile strength and add greatly to the dynamic properties. To expect to make any of these twenty-five times what the metal formerly was is expecting altogether too much. If they are doubled or trebled, a great improvement has been made and the alloying material is well worth its cost.

That greatly increased physical properties can be obtained in steels that are carefully made in any of the steel-making processes over the ordinary commercial steels that can be turned out is as much a fact as that much better and finer work can be made in any other manufacturing line if time enough is taken to do so. Tests are often made with a specially prepared steel of a given kind and comparisons made with it from stock steels of noted brands. Such comparisons cannot help but be misleading and produce unfair comparisons.

The impurities, which are the real weakening elements of steel, can be much more readily removed in a small furnace making a small batch, or heat, of metal than in a large furnace making a large one, and it is therefore unjust to compare the physical properties of one steel made in a small heat and another steel made in a large one, no matter what the method or process by which it is made. It is too often the case that our comparative tests are obtained in this way.

When Turning a Curve

When rounding a curve with a heavy automobile there are a number of stresses set up in the car at any speed. These stresses become more severe as the speed increases, but the strains increase in intensity with the square of the speed, so that a little added speed means greatly augmented stresses.

AN automobile to be safe must, under all conditions, be in a state of stable equilibrium. This is a condition which is very simply maintained when the car is standing still, or when running at moderate speeds along a level road, but when a srarp turn is negotiated at high speed the matter becomes of an entirely different nature. Referring to Fig. 1, two roads of width S are depicted crossing each other at right angles. In turning from one into the other a turn of radius R is made, this radius being very nearly equal, as a rule, to the width of the road. As the car goes around this curve it is acted upon by a force which tends to throw it away from the center in the same way that a ball tied upon a string and swung around will tend to break the string and fly away from the hand which is swinging it. This force is called the centrifugal force, and its pull in pounds is denoted in the figure by F.

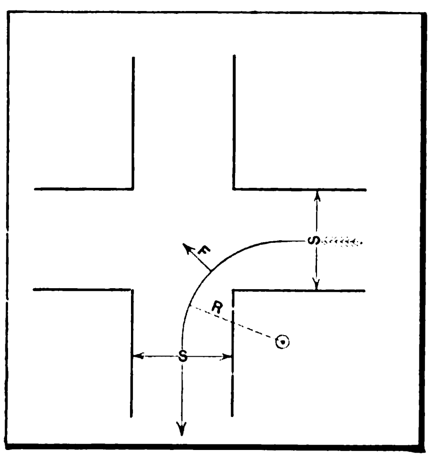

Fig. 1—Diagram of course usually taken in rounding a curve—S is the width of the road, R the radius of the curve and F the direction of the centrifugal force

In a body which is subjected to the stresses of weight and centrifugal force, they may be figured as acting at the center of gravity of that body. So that it is easy to see that when the car is subjected to the force due to its turning the curve, there is a marked tendency for it to turn over, the amount of which is measured in foot-pounds by the product of the centrifugal force in pounds and the height of the center of gravity of the car from the ground in feet. Referring to Fig. 2, let G be the center of gravity of the car, F the centrifugal force in pounds, a the height of the center of gravity above the ground in feet, b one-half the tread or the distance of the center of gravity from the point of contact of the wheel with the ground, measured horizontally. W is the weight of the machine acting vertically downward from the center of gravity, A and B are the points of contact of the wheels and the ground. As the car is turning a curve the righting leverage must be greater than the upsetting moment to keep the car in stable equilibrium; that is, Wb must be greater than Fa. In case the car should turn over, owing to the fact that Fa was greater than Wb, it would turn over about A, the outside wheels.

The speed at which the two moments are equal in turning a curve of given radius is called the critical speed. At this point the car is in neutral equilibrium; that is, if it should be slightly inclined, it would tend to fall still further out of the perpendicular instead of tending to return to its normal position. This speed can be determined by equating the two moments and solving for the speed, as follows:

Let $aF = bW$ (Fig. 2).

$$F = \frac{Wv^2}{gR} \text{ therefore } \frac{aWv^2}{gR} = bW \text{ and } v^2 = \frac{bgR}{a} = 32.16\frac{bR}{a} \quad (1)$$

where the symbols are as described above for Fig. 2—and v is the critical speed. From the last equation it is seen that the greatest possible speed in turning a curve varies directly with b and R, and, inversely, with a. That is, it would be greater to maintain a greater speed around a given curve of radius R without overturning if the tread of the wheels or the radius of the curve were greater or the center of gravity of the car were nearer to the ground.

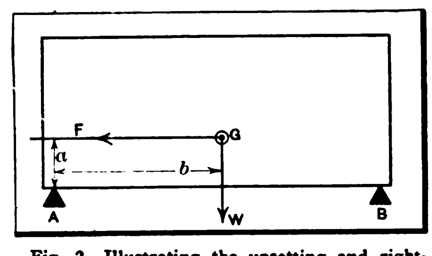

Fig. 2—Illustrating the upsetting and righting moments—G is the center of gravity, F the centrifugal force, W the weight of the car, a the upsetting arm, b the righting arm. A and B are the points of support

From the above it is seen that the weight factor is not of any influence in so far as the turning over of the car is concerned, since it is on both sides of the equation point. We are all aware though, that a light car will not "hold the road" as well as a car of greater weight. This is not because of its turning over on account of rounding a curve, but due to the side-slipping of the car which introduces entirely different factors. In this case the car is given a momentum away from the center of the road because the centrifugal force F is greater than the resistance to sliding of the wheels. To maintain equilibrium all forces must be balanced by equal and opposite forces. Hence the force F will have to be counteracted by the frictional resistance set up between the tire and the road which will be measured by the weight multiplied by the coefficient of friction. If the coefficient of friction is f, the critical point of side slipping will be reached when $fW = F$ or $f = \frac{F}{W}$. To determine the valuations of the different factors in a practical case, an example may be taken to show both the inclination of the car to turn over and to side slip.

Let W be 3,000 pounds; R, 20 feet; a, 2 feet; b, 2 1-3 feet, and v, 22 feet per second: F will equal $\frac{Wv^2}{gR}$ or $\frac{3000 \times 22 \times 22}{32.16 \times 20} =$

2257 pounds. This side pull F, exerts a turning moment over the outside wheels of aF foot-pounds or, in the above case of 4514 foot-pounds, which is resisted by the moment of the weight of the car about the outer wheels bW, which is equal to 7000 foot-pounds in this case. This leaves a margin of safety of about 2500 foot-pounds in the case considered. To find the critical speed of this car going at the above speed around the same curve, 7000 foot-pounds must be equated to aF or from the formula for the critical speed (1) $v = \sqrt{32.16 \frac{2.33 \times 20}{2}} = 27.4$ feet per second. That is, the car would turn over at a speed in excess of 27.4 feet per second, or 18 2-3 miles an hour, approximately.

Besides turning over the tendency of the car to slip sideways may be measured mathematically by equating the side pull F, which in the above case is 2257 pounds, and the frictional resistance of the road to the side slipping, which is measured by fW where f is the coefficient of friction, and is a constant for given road conditions. Equating: $3000\ f = 2257$ or $f = \frac{2257}{3000} = .752$. That is, if under the given conditions the coefficient of friction were .752, the car would be just on the point of slipping. It is seen that with a fixed coefficient of friction the resistance to side slipping depends directly upon the weight of the car.

While from a theoretical point of view the side slipping of the car would continue until the radius of the curve were changed or the road conditions were different, the skillful driver offsets the tendency by a skillful manipulation of the steering wheel, and the slipping is often confined in this manner to one pair of wheels; it is then known as a skid. In this case one set of wheels act as a pivot for the other pair. The skidding tendency is checked in many cases by disengaging the clutch and releasing the brakes so that the wheels are free to turn. On wet and slippery days when the coefficient of friction will be reduced to a minimum, the greatest danger ensues and curves are of necessity negotiated at the lowest possible speeds.

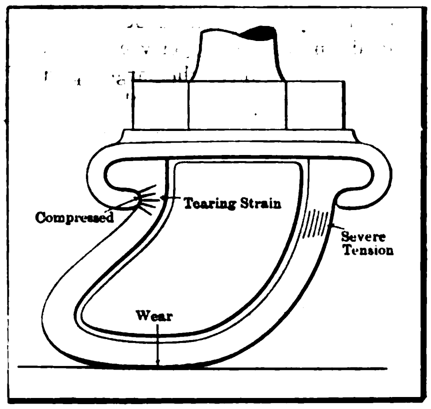

Fig. 3—Showing the strain on a soft tire in rounding a curve. The points of severest stress are indicated.

Two ways in which the life of the car or its parts may be made as long as possible in connection with driving around curves are throwing out the clutch and in maintaining the tires at the required pressure. The former is for the purpose of preventing unnecessary torsional stresses in the transmission and the latter to cut down the tire bills, which are always a little larger than the average motorist desires. Fig. 3 shows the distortion which takes place in a soft tire when turning a curve. Recurring strains of this kind will soon spoil the best of tires.

Calendar of Coming Events

Handy List of Future Competitive and Show Fixtures

Shows

Jan. 1-5, 1912......New York City, Grand Central Palace, Annual Show, Automobile Manufacturers' Association of America.
Jan. 6-13..........New York City, Madison Square Garden, Twelfth Annual Show, Pleasure Car Division, Automobile Board of Trade.
Jan. 10-17..........New York City, Madison Square Garden, Annual Show, Motor and Accessories Manufacturers.
Jan. 10-17..........New York City, Grand Central Palace, Twelfth Annual Show, National Association of Automobile Manufacturers.
Jan. 15-20..........New York City, Madison Square Garden, Twelfth Annual Show, Commercial Division, Automobile Board of Trade.
Jan. 27-Feb. 10....Chicago Coliseum, Eleventh Annual Automobile Show under the auspices of the National Association of Automobile Manufacturers.

Race Meets, Runs, Hill-Climbs, Etc.

Sept. 1............Oklahoma, Reliability Run, *Daily Oklahoman*.
Sept. 2............Pottstown, Pa., Track Races, South Jersey Motor Club.
Sept. 2, 3, 4.......Kansas City, Mo., Track Races, Automobile Club of Kansas City.
Sept. 2-4..........Amarillo, Tex., Track Races, Panhandle Auto Fair Association.
Sept. 2-4..........Brighton Beach, N. Y., Track Races.
Sept. 3............Columbus, O., 200-mile Race, Columbus Automobile Club.
Sept. 4............Scranton, Pa., Track Races, Automobile Association of Scranton.
Sept. 4............Denver, Col., Track Races, Denver Motor Club.
Sept. 4............Salem, N. J., Track Races, South Jersey Motor Club.
Sept. 4, 5, 6.......Old Orchard, Me., Beach Races, Old Orchard Automobile Association.
Sept. 6............Detroit, Mich., Reliability Run, Wolverine Automobile Club.
Sept. 6-9..........Buffalo, N. Y., Grade I, Reliability Run, Automobile Club of Buffalo.
Sept. 7-8..........Philadelphia, Track Races, Philadelphia Auto Trade Association.
Sept. 8-9..........Hamline, Minn., Track Races, Minnesota State Automobile Association.
Sept. 9............Augusta, Me., Hill Climb.
Sept. 9............Cincinnati, O., Road Race, Fern Bank Dam Association.
Sept. 9............Hartford, Conn., Track Races, Connecticut Fair Association.
Sept. 9............Port Jefferson, L. I., Hill Climb, Port Jefferson Automobile Club.
Sept. 9............Riverhead, L. I., Road Race, Port Jefferson Automobile Club.
Sept. 13...........Grand Rapids, Mich., Track Races, Michigan State Auto Association.
Sept. 15...........Knoxville, Tenn., Track Races, Appalachian Exposition.
Sept. 16...........Syracuse, N. Y., Track Races, Automobile Club and Dealers.
Sept. 18-20........Chicago, Ill., Commercial Reliability Run, Chicago Motor Club.
Sept. 19...........Burlington, Vt., Reliability Run, Merchants' Protective Association.
Sept. 23...........Philadelphia (Point Breeze), Track Races, Philadelphia Automobile Trade Association.
Sept. 23-25........Detroit, Mich., Track Races, Michigan State Agricultural Society.

THE ELGIN RACES

EVERYBODY connected with automobiling from a manufacturing as well as from a sporting point of view regrets the fatal accidents in connection with the national stock chassis races held last week on the Elgin circuit. These accidents arouse tremendous attention from ocean to ocean, but the saner element always deplores them. We can only mount to higher levels by profiting by the errors of the past, and every accident should be an object lesson to every manufacturer. The two Elgin accidents were peculiar. One that happened in practice remains a mystery. It occurred on a perfect stretch of roadway without a ditch on either side where the car ran onto the grass. The other accident on race day was also on a perfect roadway with ample width. In both cases a tire exploded, the car took the ditch and finally capsized in getting onto the roadway again. In a word the tire was the prime cause of the accident.

Tires will explode; the terrific heat generated by the fast pace is responsible for this and the remedy can only be found in the quick work of the driver. It calls for the quickest action on the steering wheel; often the quickest is not quick enough. If a front tire goes the exigency calls for a certain operation, and if a rear tire goes another course must be pursued. The majority of racing drivers are entirely familiar with these operations; they know what to do, but sometimes fate is against them. One partial remedy is always to make sure by inspection before each race that the tires are in perfect condition and securely fastened to the rims.

PREVENT RATHER THAN CURE

MANY automobilists try to progress by driving through reverse gear when it comes to legislation governing the automobile. Every week or so we read of a new law being enacted restricting the speed of a motor car to four or six miles per hour on a corner or at a crossing, and a few weeks later we read of how the automobile owners have banded themselves together to fight the new law in the courts. The automobilists were a little slow. Instead of fighting in the courts they should have started before the laws were finally passed in the Legislature. It is easier to fight a bill in the Legislature than it is to carry it through all of the law courts and even up to the Supreme Court of the land. Prevention is better and cheaper than cure.

The automobile manufacturer and dealer is often too busy with his business of buying and selling cars to think of legislation before it is enacted, and when it is enacted he almost stampedes. One example of this is the recent prohibitive legislation in Detroit, the biggest automobile manufacturing city in the country. An absurd law has been passed; this law is being violated every day by practically every car owner; fines as high as $200 are being assessed and already thousands of dollars have been collected in fines. The money that has already been spent in fines would, if properly used before legislation was enacted, have resulted in the passage of a sane measure. What is happening in Detroit is happening month after month in a score of other cities. It is a Rip Van Winkle policy until the law is enforced and then a money-wasting one. Every locality should have its legal representative who watches all pending legislation and every effort should be made for rational legislation before it is too late. Banding together to keep an eye on possibly unwise legislation must not be interpreted as being opposed to all legislation. The object is to defeat irrational measures before their enactment, when it can be done at much less expense than after such laws have been passed by the Solons and inscribed on the statute books

* * *

TELL THE TRUTH

ONE great detriment to the early popularization of the freight automobile is the tendency on the part of salesmen to overstate the benefits that will result from the installation of a motor service in a large commercial or manufacturing establishment. It would seem to be the part of wisdom that the prospective purchaser be told the exact requirements of the situation. He must not be allowed to buy under the delusion that his trucks and delivery wagons may be safely entrusted to the tender mercies of the erstwhile teamster, boy or man, lacking experience and working for wages which are anything but an incentive to the acquisition of the knowledge requisite to a proper performance of his duties. Nor must the purchaser be allowed to go on his way without being warned of the dire results which will follow upon the overloading of his trucks and wagons. A freight automobile system should not be installed without thorough preparation; drivers should be trained and all the details of the system—repairs, relief and service—should be reckoned with before undertaking such a radical change.

Progress Shown in Elgin Races

Fast Time Indicates Improvements in Cars

H. A. Bonnell, General Manager of the Automobile Board of Trade, points out the great lessons to be learned from the recent Elgin National Stock Chassis races, particularly emphasizing the advancement in the art of building automobiles on stock lines and for stock purposes.

RACES such as those held at Elgin last Friday and Saturday demonstrate the progress in making automobiles about as forcibly as anything could, according to H. A. Bonnell, general manager of the Automobile Board of Trade. Improvement in the course undoubtedly had some effect upon the fast time made this year, but it would hardly account for the tremendous reductions of the record in three of the races. In discussing the matter Mr. Bonnell said:

"That there has been great progress made in the manufacture of automobiles this year is clearly indicated by the splendid showing made by the stock cars that competed over the Elgin course last week. The roads were in better shape than ever before and a number of narrow places had been improved, all of which means that the normal time ought to have been faster than in previous years, but hardly as much as the actual figures show, unless some betterments had been made in the construction of the cars themselves.

"Take the showing of the Lozier entry in the Elgin National race. Last year the Lozier car won a splendid race rather easily in 292:29:84, or an average of 62.5 miles an hour. This year, with substantially the same type of car, which of course carried the improvements and refinements of the current model, the speed made by it was 69.78 miles per hour for eight laps. A difference of over 7 miles an hour in the rate of speed accomplished could hardly have been credited in its entirety to the difference in the condition of the course. The car itself must have been faster.

"The mishaps that befell several of the contestants in the big race at various stages of the event might all be laid to increased vibration caused by minute bumps in the roadway, which would argue that much more emphasis should be laid upon the quality of the cars themselves. These mishaps included burned-out bearings, broken gasoline line and the fracture of parts that were particularly subjected to the intense vibration, all of which are accidents likely to occur from the combination of great speed with uneven roads.

"National 2, driven by Zengel, which won the race, made the thirty-six circuits almost seventeen minutes faster than the winning time of the Lozier in 1910 and averaged better than 66 miles an hour throughout. From any angle this performance is excellent as it means the sustained speed of the fastest railroad train carried over a distance that would discourage the best equipped railroad in the world. Twice the winner paused for fuel and then went on without a skip to a fine victory. It means that if there was a protected, straightaway speedway from New York to Chicago a business man might make the distance in five or six hours less than the great railway trains, if he happened to be in a big hurry.

"Of course the difficulties that were met in the Elgin roads really served a purpose in detecting weaknesses and while the mishaps that caused the withdrawal of several of the cars were trifling in themselves they were sufficient to insure defeat despite the fact that they could have been repaired with but small delay. When the leading group in a long race, such as the Elgin, is making better than 66 miles an hour and going along without a miss it is little use to take a handicap of fifteen minutes of half an hour by making repairs and then run the chance of again breaking down in the tremendous spurt that would be necessary to bring a car back into contention for the lead.

"The inexorable rule of mechanics that wear on tires and mechanism is in proportion to the square of the velocity, while the speed is represented only by the velocity itself, is one of those things that cannot be avoided in making up time and the right thing to do under the circumstances is to withdraw. Take for example the experience with Alco 7 (Hartman). According to the reports, this car suffered a break in its gasoline line while going nicely in the last half of the race. Such an accident is not sufficient to retire a car from competition, but to repair it would require probably 15 minutes. The car was not right up among the leaders when the mishap occurred and if it had continued it would have been heavily handicapped. If Hartman had tried to make up the lost ground by opening wide his throttle the chances of accident would have been emphasized.

"The running of the Illinois Cup race proved to be a rather hollow victory for the National also, but the fact should not be lost sight of that all four cars entered in this event were running smartly at the end and that all would have finished in good time if they had been allowed to proceed. The winner beat the time of last year's winner by 15 minutes. In the Kane County race for 231-300 cars the most astonishing showing was made. Seven cars out of the eleven that started completed the full distance and the winner lowered the record of last year in this race over 27 minutes.

"The cars that ran in the Kane County Cup race are automobiles such as the average owner drives and such as one may see on the streets and boulevards at any time. Those in the Aurora Cup race are lighter cars than the contestants in the Kane County race, while the entries in the Illinois were big cars with power enough to keep them away from the dust of almost anything they are likely to meet on the road. In the Elgin National the contestants were not limited as to piston displacement save that they were obliged to be under 600 cubic inches. This let in the highest powered cars manufactured in the United States in stock models.

"Now the best of such races as those run at Elgin is the fact that they are supervised by technical experts to the end that the public may be assured that the cars that perform in competition are identical with the cars of the same model sold over the counters of the various automobile salesrooms. The average buyer does not wish to enter track or road competition, but he does want to know that simple pressure on the accelerator will develop high power and great speed.

"The idea of such races as those at Elgin is to afford an object lesson to the public. The whole effort is made to show automobile owners and prospective buyers the quality of the contestants. In special races there are two objects, first to afford the public a spectacle and second to show manufacturers the merits and demerits of their special productions. The recent Indianapolis race is within this latter category, while the Elgin races come directly within the former.

Detroit in the News of the Week

Cadillac Cars to Have Electric Self-Starter

Studebaker Corporation invites 1800 dealers to visit its plants—Automobile industry has almost doubled Michigan's investment in manufacturing within five years—General Motors stock now formally listed in the big exchanges—Chalmers predicts record year for industry and points out advantages of export trade and danger of over-production—Packard truck completes transcontinental run in forty-seven days from start to finish.

DETROIT, Aug. 28—Formal announcement of the 1912 Cadillac, awaited with interest by the entire trade for some time, has been made at last, and reports of radical innovations, current for some time as matters of gossip, were confirmed in part. According to the announcement, the new Cadillacs will be equipped with an electric device capable of automatically starting the motor, furnishing current for all the lights, and supplying ignition for the motor. The device is of the storage battery principle, a dynamo generating electricity being attached to the motor.

The starting device is operated by retarding the spark lever and pushing gently down on the clutch. It is said that the battery when charged, is capable of turning the motor for 20 minutes. When the motor starts its explosions, the electric device stores up current until full charged, when it automatically cuts off from the motor. As an ignition device, the Cadillac's equipment will furnish a spark at slow speeds from the storage battery. At 300 r.p.m. the apparatus shifts automatically and furnishes the spark through the high-tension system.

Other changes announced for the 1912 Cadillac are 36-inch wheels, new carbureter, larger brake drums, steel bodies, and increased gasoline capacity. All the 1912 models will be of the enclosed front type.

The E-M-F Company plants of the Studebaker Corporation start this week a series of systematic gatherings of dealers which will be on a larger scale than anything in the history of the industry. The company has invited every one of its 1,800 retailers to visit the factory for two days, making the trip at the company's expense and being its guests while in the city. The visits will be made under the auspices of the various branch managers, dealers tributary to the branches at Atlanta, Ga., and Birmingham, Ala., being selected to open the series.

It is the aim of the Studebaker Corporation to become thoroughly acquainted with its dealers and to familiarize the dealers with the manufacturing processes by this method. The visit of the dealers and the arrangements for entertainment are in the hands of Paul Smith, former assistant general sales manager, who has been appointed sales manager.

The motor car industry is given large credit for the enormous increase which U. S. census statistics show for Michigan, during the past five years. During that period, Michigan's investment in manufacturing increased from $337,894,000 to $583,947,000; salaries and wages paid from $98,749,000 to $153,838,000; and the value of the products less cost of material, from $190,039,000 to $316,497,000.

While the most remarkable strides have been made by Detroit, Flint, Pontiac and Lansing, the state in general has become a hive of automobile activity. In fact, the largest increase in number of plants this year has been chronicled outside the centers mentioned. One of the new factories is that of the Gaylord Motor Car Co. of Gaylord. This city is located well up in the northern part of the lower peninsula. The Gaylord Co. already has experimentary models undergoing tests. A. B. C. Comstock, a wealthy lumberman, is president; John A. Hixon, vice-president; John J. Munger, secretary and J. Lee Morford, treasurer.

Another new Michigan concern is the Michigan Adjustable Hub Co., of Bay City, which has started the manufacture f a boltless, adjustable wheel, said to be capable of withstanding a load of 43,000 pounds. The company is investing heavily in machinery and its product will be a simple job to assemble, when the automatic machinery has done its work.

A local change of note is the increase of the capital of the Automobile Manufacturing & Engineering Co., of Detroit, from $1,000 to $50,000.

It is announced from the local headquarters of the General Motors Co., that the New York Stock Exchange had granted an application for the listing of the company's stock. Similar arrangements are being made in Boston. The first transaction on the New York exchange, in the stock was the sale of 100 shares at 51 1-2.

The new plant of the Continental Motor Co. is about ready for the installation of machinery. It has been definitely decided that the Detroit factory will be made its general headquarters and the officers, who have formerly been attached to the plant at Muskegon, are now removing their families to Detroit.

The Abbott Motor Car Co. has established a Detroit branch in the new Dodge Building, placing E. C. Thompson of the factory sales organization in charge. A service department will be attached.

The Regal Co. announces that, some time in the near future, one of the firm's underslung "Twenties" will leave Detroit to establish a speed record between this city and Chicago, and return. It is planned to make the affair a non-stop run, as well as a speed demonstration. The car will be driven by L. J. Wilcox, race driver, and will carry C. B. Sims of the Regal advertising department. A trial trip was recently made to acquaint the driver with the road and the conditions which will be encountered.

The Wolverine Automobile Club is prosecuting an energetic campaign of road posting. The club's commitee, in an Everitt "30" loaned by the Metzger Co. for the purpose, has already posted both the main routes between Detroit and Toledo and is now at work on the main-traveled route between Detroit and Port Huron. The work will be prosecuted through the season, the next routes to be posted being Detroit to Saginaw, and Detroit to Chicago, the last-mentioned highway being by way of Battle Creek and Kalamazoo. Signs of 1-inch lumber are used, black background and a large white arrow pointing the main highway. The name of the city toward which the route runs, is tacked to each sign in copper letters. Through the courtesy of the Michigan Bell and Home Telephone companies, the Wolvering Club's committee has been able to make use of telephone poles for nearly all its signs. This has greatly facilitated the work of posting.

In a recent address on "The Future of the Automobile Trade"

President Hugh Chalmers of the Chalmers Motor Co. stated it as his belief that 1912 would be a most prosperous year for the industry. He saw but one danger—that of over-production, and urged fellow manufacturers to make careful estimates of the demand before forming their plans for the year. Mr. Chalmers called especial attention to the export trade and believes that the demand for medium-priced American-made cars from abroad will continue to increase. In his belief the future of the industry lies largely in thoroughly standardized cars of this type.

The Packard Motor Car Co. received news several days ago of the successful completion of a transcontinental trip by one of its 3-ton trucks. The start from New York was made July 8 and the finish at San Francisco took place Thursday, August 24. The trip was uneventful until the territory west of Omaha was reached, after which encounters with weak bridges, deep fords, mountains and deserts made it one of great difficulty. E. L. Burnett, of Detroit, drove the car. With him were W. T. Fishleigh and Arnold Hainer.

The Warren Motor Car Co. announces the establishment of a London agency with the firm of McCurds & Co. A representative is also arranging for a retail dealer in Paris.

Crude Rubber Holds at Lower Level

AKRON, O., Aug. 28—Crude rubber prices remain lower than they have been for several years, and indications are for modifications in tire prices for the new season. A steady decline in crude rubber quotations has been noticed for nearly three years, ranging from a high point of $3.00 a pound, to "dollar rubber," which was the rate recently. The present rate of about $1.20 is considered by local manufacturers to be likely to continue, and they declare that in all probability there can be no return to the former high prices of the crude product.

The high rubber price is credited by local manufacturers directly to London and Brazilian attempts to corner the crude rubber market. When Brazilian jobbers and producers combined to raise prices by withholding rubber from the market, and at the same time borrowed money from the Brazilian government on what they stored, American manufacturers bought as little as possible, and fought the combine as hard as they could, even at the expense of their own ability to turn out orders, and the corner finally broke. The slump has been steadily continued ever since.

Baltimore Dickering for Last Toll Road

BALTIMORE, MD., Aug. 28—A meeting of citizens of Baltimore was held in Mayor Preston's office to determine upon a price, if possible, for the purchase of the tollgate on the Reisterstown Turnpike, near the Park Heights avenue entrance of Druid Hill Park, the only tollroad remaining within the city limits. At the conclusion of the discussion Mayor Preston asked the directors of the turnpike company if they would accept $70,000. They said that they would recommend the acceptance of $75,000, $5,000 less than they asked the Good Roads Commission and $15,000 more than the Commission offered.

Before saying the city would consent the Mayor persuaded the directors to let the city examine the company's books. This will be done by experts. In the event of a disagreement between the city and company abutting property-owners present offered to donate enough land to build a road parallel to the toll road so that the city would have an outlet in that section without using the toll road.

Quaker Trade Meet Postponed a Week

PHILADELPHIA, Aug. 28—Originally scheduled to take place on Saturday, September 16, the date for the race meet to be conducted by the Philadelphia Automobile Trade Association has been set forward a week and will be held at the Point Breeze track on Saturday, September 23, two weeks previous to the Fairmount Park Road Race.

By postponing the event a week not only will the meet attract a greater number of fast cars but also a larger list of the best drivers, for the originally-selected date conflicted with the meet to be held at Syracuse, N. Y., many noted machines and drivers being entered in that event. The Trade Association's original application to the American Automobile Association for sanction to hold races on September 16 had been granted, and to-day the necessary permit for a change of dates was received by Secretary J. H. Beck.

Lu Lu Temple Club Will Run

PHILADELPHIA, Aug. 28.—On Saturday, September 16, the recently organized Lu Lu Temple Automobile Club will conduct its initial social run, the objective point being Atlantic City. In addition to souvenirs to be presented each car entered before the Saturday preceding the run, special trophies will be awarded cars finishing nearest to the secret time schedules, the latter to be determined by the usual method—two secret guesses to be made, sealed until completion of the event, opened and the two times added together and divided by two, the result being the allotted time, the winners to be the cars finishing nearest to it. While in Atlantic City cars will be parked on Young's Pier. A large and representative list of entries has already been received, insuring a successful affair.

Anderson Memorial Road to Be of Service

BRETTON WOODS, N. H., Aug. 28—Within less than a month there has been subscribed to the John Anderson memorial road which is to be built in New Hampshire just $16,500. The Bretton Woods Company subscribed $5,000 and the remainder was added by motorists who knew the late Mr. Anderson personally. Under the plans now worked out the boulevard will be about 25 miles long and connect Crawford and Franconia notches. There were six grade crossings on the first plan, but a new route has been selected so that there now will be but one railroad crossing in the entire route. State Engineer Hill has gone over the route and all the officials connected with his department are enthusiastic over the road.

Fine Cup for Winner at Columbus

COLUMBUS, O., Aug. 28—Arrangements for the 200-mile automobile race to be held September 3 under the auspices of the Columbus Automobile Club, are rapidly maturing. The Hotel Hartman will give a handsome cup to the winner of the contest. The cup is 20 inches in height, bears two winged wheels and is a model of beauty. The club has contracted for three tons of calcium chloride to keep down the dust on the track. Entries for the event are coming in rapidly and it is believed there will be more than a dozen starters.

Transoceanic Balloon Finished

AKRON, O.—The gas bag for the balloon with which Melvin Vaniman will try to fly across the Atlantic in October, has been completed at the factory of the Goodyear Tire & Rubber Co. and will be shipped next week.

The gas bag alone weighs two tons and a special flat car is used for its shipment, in a box 30 feet long by 6 feet wide.

Gimbel Buys Score of Trucks

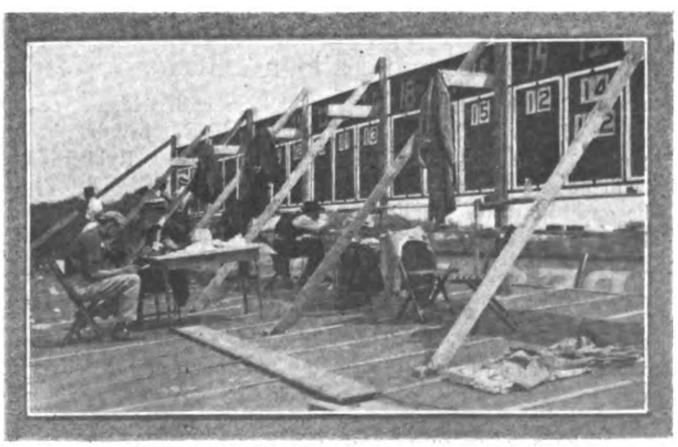
CLEVELAND, O., Aug. 28—The White Co. of Cleveland, Ohio, announces the sale of twenty of their 1,500-pound motor delivery wagons to Gimbel Bros. of New York City. Also the sale of five of these cars to The Hub clothing store of Chicago—these five cars will entirely displace the horse equipment now in use.

Records Fall at Elgin Stock Races

(*Continued from page* 340.)

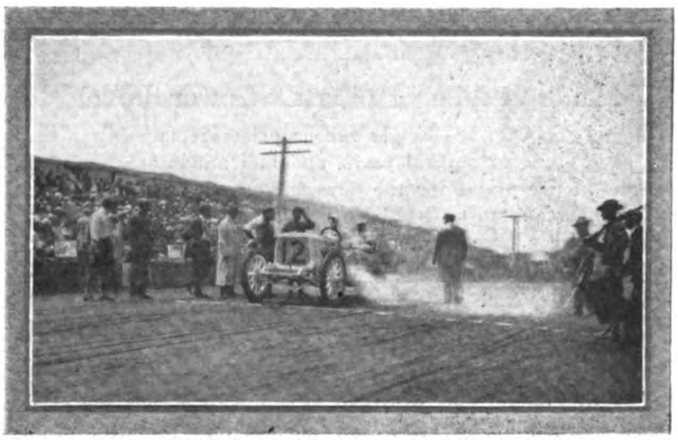
which in turn had a lead of 9 seconds over the Wishart Simplex. Grant was in fourth place, 14 seconds behind Wishart, with Mercer, the Hartman Alco, the Lee Alco and the Pope-Hartford following in the order named. In the fourth lap the Wishart Simplex moved into second place, 58 seconds behind the flying Mulford, Zengel dropping back to third place and Grant retaining fourth, the other quartet retaining their respective positions. The fifth circuit saw the Wishart Simplex, which had been making a strong bid, bowled out, the trouble being a burnt-out connecting rod bearing. As a result of the Simplex's withdrawal, Zengel once more swung into second place, 1 minute 18 seconds behind Mulford, who was still continuing his record-breaking performance, as laps in 7:14, 7:19 and 7:18 will indicate. Grant in Alco No. 1 moved up in third place, 20 seconds behind Zengel, with Hughes in the Mercer following 40 seconds behind and the Hartman Alco 13 seconds behind Hughes. The sixth, seventh and eighth rounds brought no change in the relative positions of the seven remaining contenders, although at the conclusion of the latter circuit Mulford had so consistently added to his advantage that he was now but 2 seconds short of being a full 2 minutes ahead of his nearest rival, Zengel in National No. 2. The latter was 61 seconds ahead of the Grant Alco, which in turn had almost 4 minutes' advantage over the Mercer. The Hartman Alco was about 1 1-2 minutes behind the Mercer with the Lee Alco and the Pope-Hartford far behind, and, barring accidents to the leaders, out of the race.

The Lozier's remarkable work in the first 8 rounds exemplify the old adage that the race is not always to the swift, for the big white car limped into the hospital just short of its ninth round and the announcement was megaphoned that the car was permanently out of the race with a broken connecting rod. This put the Zengel National into the lead by a margin of 1 minute 16 seconds over the Grant Alco and the huge crowd of spectators, deprived of the hope of a second win for Mulford, settled back comfortably in the belief that there would be furnished a heart-breaking contest between the two leaders. At this point the Mercer was trailing along in third place, but 42 seconds behind the Grant Alco, followed in turn by the Hartman Alco, which was 23 seconds in the rear and by the Lee Alco and the Pope-Hartford, the latter being over one-half hour behind. From the tenth to the sixteenth laps there was little to vary the monotony of the grind with the exception that Alco No. 7, which had been trailing along in fourth place, moved up to third in the twelfth round and maintained its position during four circuits. The sixteenth round saw the Mercer, which had been held up at the pits on two occasions for refilling and tire changes, regain third place, but it was nearly 4 minutes behind the Grant Alco, which was second, a trifle over 2 minutes behind the leader. The seventeenth, eighteenth, nineteenth and twentieth round saw no change in the relative positions of the six contenders, the conclusion of the last-named circuit showing Zengel to be 2 minutes 12 seconds ahead of the Grant Alco, with the Mercer in third place over 4 minutes behind, and the Hartman Alco a bad fourth, the latter having been delayed by a leak in the gasoline line, which compelled its withdrawal in the next round. The Lee Alco was plugging along in fifth place and Buck in the Pope-Hartford was plodding along doggedly many miles behind.



The "men behind the score-board" saw little of the races

On the twenty-first lap the Zengel National made its first stop, having gone over 177 miles without a let up. The stop, however, was a short one and after filling with gasoline, Zengel was away amid the cheers of the huge crowd, but with a loss of a full minute to the fast flying Grant, the margin now separating the two cars being but 1 minute 21 seconds. The Mercer, was, at this point, over 4 minutes behind the Grant Alco but still in third place. The crowd began to hope for the National-Alco duel which the inforced withdrawal of Mulford's Lozier had seemed to portend. The twenty-second lap, however, saw Grant lose all the advantage he had gained by Zengel's stop, with another minute added to the handicap that he would be compelled to overcome in order to catch the leader. Grant stopped for gasoline and water, the filling of the latter being rendered somewhat slow owing to the high pressure in the radiator, the force of the steam blowing the water aside and preventing rapid filling. This was really the deciding point in the race for first place, for barring the possibility of stops on account of tire trouble Zengel's lead was sufficient to enable him to play it safe to the end of the race, although, as it happened, he consistently out-drove Grant, in all but the very last lap, when, with the prize practically in his grasp, he negotiated one of the slowest laps of the entire thirty-six, barring, of course, those in which he was compelled to stop for supplies. These were in the twenty-first lap, as above mentioned, and again in the thirty-second lap, on both of which occasions the crew at the pit performed their work in jig time. Grant's second stop—for gasoline and water—also in the thirty-second round, gave a comparison of the working of the two pit crews, the National outfit showing a sprightliness that cast the efforts of the Alco contingent into the shade, although the fact that the Alco had to take on water in addition to the gasoline was what really caused the delay.

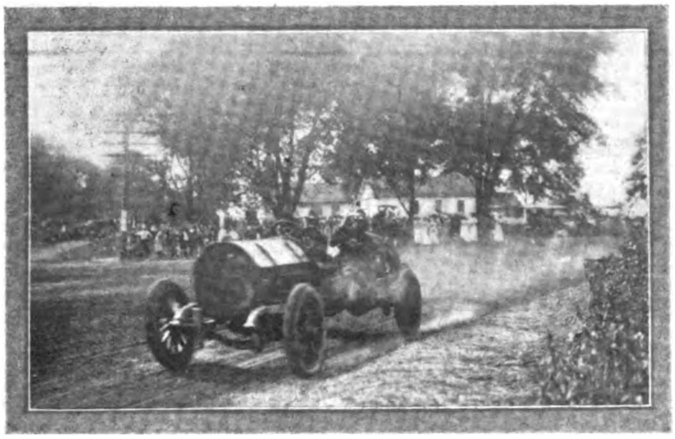


The Lozier was the last to start in the Elgin Cup race, but was soon breaking the record on every lap

The first position settled, barring accidents, the race for second place between the Grant Alco and Mercer No. 9 now attracted the attention of the spectators. When Grant made his long stop in the thirty-second round Hughes saw his opportunity and at the close of that lap he had almost closed up the gap which separated his car from second place, Grant's margin of lead being but 24 seconds. This was still further reduced in the thirty-third round to 16 seconds, increased to 17 seconds in the thirty-fourth lap and reduced to 12 seconds at the conclusion of the thirty-fifth circuit, the next to the last of the race. The sympathies of the crowd seemed to be with Hughes in the Mercer, his brilliant victory of the preceding day having made him a general favorite. The Alco, with its excess of power, was enabled, however, to hold the Mercer safe and although the latter covered the last lap a second faster than its rival, it was unable to close up the gap, a matter of but about 11 seconds separating the two cars at the finish. Alco No. 5, which had met with a variety of troubles throughout the race, was still running at its conclusion, having covered thirty-two of the thirty-six laps—about 272 miles.

What Happened at the Pits

An hour before starting time on the first day of the Elgin National Stock Chassis Races, the racing cars entered in the Illinois, Kane County and Aurora cup events began to line up opposite their respective pits, where they immediately were seized upon by the technical committee for the final examination.



Alco, No. 5, which finished fourth in the big race, and was still running at its close

This examination was not a fruitless one, for several of the cars appeared for the start with ignition wires and gasoline pipes taped in a very much more substantial manner than was customary in the regular stock chassis construction. All of these extra precautions counted for naught, for this tape had to be removed, much to the chagrin of the drivers and mechanicians.

Herein lies one of the many benefits to be obtained from stock car racing. The weaknesses will out, and the maker, if he be a conscientious one, will profit by his experience and strengthen not only his racing cars but those which he sells to the public as well.

At 10:40 a. m. nineteen out of the twenty-three cars entered in the three events, were lined up near the tape in the order of their start. The three Falcars entered had not even shown up for practice and the Cino No. 26 had been disabled in practice the day before.

Promptly at 11 o'clock, the first car was sent off by Starter Wagner. This was the National No. 1, with Donald Herr at the wheel. The rest of the cars entered in the 203-mile Illinois Cup and 169-mile Kane County events followed at intervals of 15 seconds; and 15 minutes later the cars entered in the 135-mile Aurora Cup contest followed.

The last car hardly had left the tape when the first halt was made at the pits, Robillard in a Staver stopping for a tire. Half a minute later Jeffkins in a Velie also stopped for a minute at his pit for a tire and water; and four minutes after he had gotten away Gaston Morris (Cole No. 21) drew up to the pit for a tire. It was evident that these drivers were pushing their mounts to the limit, as each of the trio required a new tire at the end of the first lap.

At the end of his second lap Rainey, who was driving Burt's Cino car, stopped at the Cino pit to exchange an injured tire, which had been replaced on the road, for a fresh one. The Velie driven by Stickney was the first to suffer mechanical trouble, at the end of the third lap a stop of 12 minutes was made during which time Stickney replaced a couple of pushrods that had become stuck in their guides; while the mechanician worked on the hand oil pump, which had broken. While these repairs were being made, Armstrong in his Colby stopped for 4 minutes to replace a reinforcement bolt that had been lost from the engine gearcase. The sleeve that is used inside of the case had dropped down into the case and was rattling around harmlessly, but considerable oil was being lost through the bolt holes. For the want of an extra bolt, the holes were plugged with wood and the car again sent on its way. As Armstrong drew away from his pit, Ogren in another Colby coasted past and brought his car to a stop about 100 yards beyond the repair pits, where it was left throughout the race. There had been a leak in the oil supply and the pistons had seized in the cylinders for the want of sufficient lubricant.

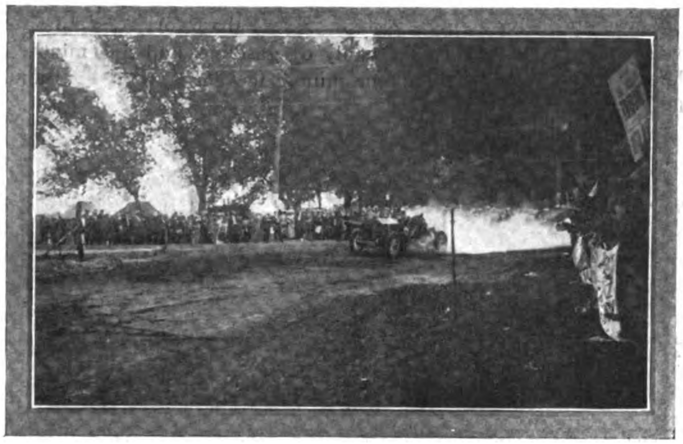
The Staver, driven by Monckmeier, was brought to a halt at the pits at the end of the fifth lap, so that the auxiliary oil tank which had been broken could be removed, and water taken on. For the want of oil, the motor had become so hot that when the radiator cap was loosened it shot up into the air, and water and steam spouted from the radiator. In four minutes, however, the little car again went on its way.

Armstrong's Colby was again brought to a stop at the pits at the end of the seventh lap. At this time 9 minutes were lost. The nut from the right rear spring shackle had been lost, and was being replaced by the driver, while the mechanician was sent down the course to take a bolt from the engine gearcase of Ogren's disabled car. Having replaced the lost engine bolt and fitted a new bolt in the spring shackle the car was again ready except for the want of oil to replace that which had been lost through the bolt holes in the engine gearcase. It happened that the pit attendants had neglected to put in an extra supply of oil and after several minutes' delay the car started off without it.

Jeffkins' Velie stopped at the pits for the second and last time on its eleventh lap, to take on oil and adjust the carbureter. Two minutes were required to do the work. Fifteen minutes later Stickney stopped for 9 minutes to replace a couple more valve tappets, and take on water and gasoline.

After making six more laps on a diminished supply of oil in the motor, Armstrong brought his Colby to a stop in front of the pit. A supply of oil had been obtained, but when an effort was made to pour it into the tank the tires were in the way and no funnel was at hand, the result was that half the oil was poured on the ground and the tires, and half into the tank. The motor was so stiff from running so long without sufficient lubricant that the mechanician could not crank it; but a husky pit attendant managed to do this and car was again in the race after a delay of four minutes. That the Colby company is new in the racing game was very apparent; too much

The press stand and score-board facilities were complete in every respect



National No. 1, winner of the Illinois Cup, rounding Hoornbeck's Corner

was left to Pearce, the driver of the third Colby entry, who had his hands full during the race in bringing his car into third place at the finish. A much better showing might have been made by the other Colby entries had it not been for the inefficiency of the repair pit management and equipment.

The last stop made at the pits was made by Robbins' Abbott-Detroit, and was due to a lost magneto coupling.

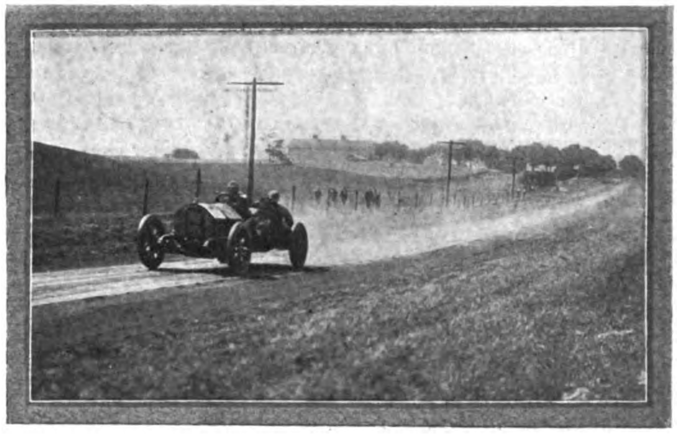
The Pits on the Second Day

With one or two exceptions, there was considerable more snap to the work of the pit attendants during the big race pulled off on the second day. Johnny Aitken's National was the first of the big cars entered in the Elgin Cup event to stop at the pits, and this was at the end of the first lap. The auxiliary air-valve spring of the carbureter seemed to be at fault, for it was replaced by a new one, while Johnny fussed around the pit, threatening to quit at once. In three minutes, however, the carbureter was repaired and away he went.

The next stop was made by Buck in a Pope-Hartford to take on a fresh tire in place of one which had been replaced on the road. Less than a minute was required to make the change. This was just the start of considerable tire trouble for Buck, which eventually caused the death of both Buck and Jacobs, his mechanician.

After making two laps in excellent time Ralph DePalma's Simplex was silently brought to a stop at the side of the road at the approaching end of the pits. The engine had been stopped some distance up the road and the car had simply coasted down to the grandstand where it was left by the roadside. The flywheel had broken. At the end of the fourth lap Buck again brought his Pope-Hartford to a halt at the pits for another tire and to remove the speedometer shaft which was broken off when the tire of the right front wheel came off. A few minutes later Johnny Aitken's National rolled up to the pits, then backed off onto the side ot the road behind DePalma's disabled Simplex; the rear cylinder was cracked.

Buck stopped again on the seventh lap to take on another tire,



The Mercer (Hughes) burning up the backstretch at a 65-mile clip

and five minutes later Ralph Mulford's Lozier rolled down on the side of the road behind Aitken's National. A connecting rod bearing of the front cylinder had been burnt out, the rod had been broken and had pushed a great hole in the crankcase, the

oil had been lost, and the motor was running spasmodically from the overheated condition with the ignition cut out. The great race was hardly started, and three of the most prominent cars were out of it.

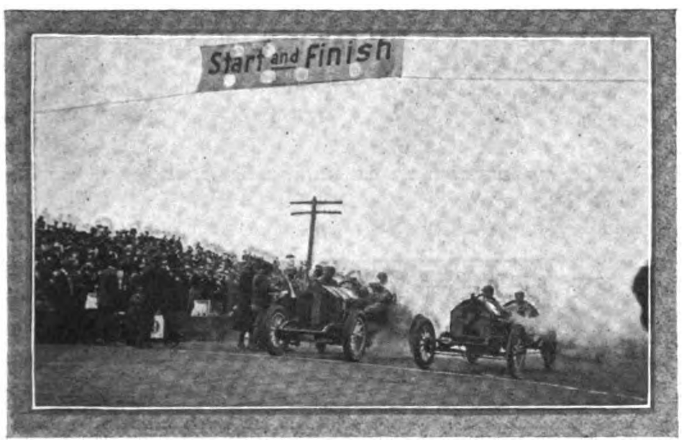
After succeeding in making four laps without stopping at the pits for tires, Buck came up to the grandstand at the end of the eighth with the right rear tire dangling from the axle. Three minutes elapsed before the old tire was removed and a new one replaced. By this time the Pope-Hartford pit had used up all of its extra tubes, and the team manager was kept busy borrowing tubes from officials and others having spare tubes in their cars of the required size.

Frank Lee's Alco made its first stop at the pits on the eleventh lap; two right rear and one left rear tires had been replaced on the road and the stop was made to take on a fresh supply. There also was some trouble with the hand oil pump so the piston was removed and the cylinder plugged with a cork. After replenishing the water supply in the radiator, the car was again put under way; three minutes' time having been lost. Harry Hartman's Alco made its first stop at the pits at the end of the fourteenth lap, and two rear tires were changed and water administered to both the crew and the car.

Buck, who was finishing his twelfth lap, made the next stop to take on a tire. A few minutes later Hartman again drove up with his Alco to take on oil and gasoline, change a left rear tire, and replace a spark plug lead that had become disconnected. This caused a delay of four minutes.

There was considerable excitement in many of the pits when Len Zengel in the winning National drove up to the pits for the first time at the end of his twenty-first lap. He did not tarry long, however, for in half a minute he was again on his way. At no time could it be said that the pit attendants of the National outfit were lacking in agility, but on this occasion they certainly exhibited some speed.

Frank Lee's Alco drew up to the pits on its eighteenth lap for



Line-up at the start of the Illinois Cup race on the first day

oil, water and gasoline, and to replace the left rear tire; and during the four minutes consumed Harry Grant also brought his car to a stop for the first time during the race. The stop lasted for but a minute and a half, during which time gasoline and water were taken on. Even this, however, was rather poor service on the part of the pit attendants, for it took the National but one-half minute to take on gasoline, water, and oil as well At the end of his sixteenth lap Buck made another stop for oil, gasoline and tires.

Hughie Hughes, whose little Mercer had been running like a watch, stopped at the pit for the first time at the end of the twenty-first lap for gasoline, oil and water. Lee's Alco stopped for one minute on the twenty-fourth lap to replace the left rear tire.

At the end of the thirty-second lap Len Zengle brought considerable joy to the hearts of those in the Alco pit by bringing his car to a stop at the National pit for the second time. Their joy was short-lived, however, for in less than forty seconds he was off again with a fresh supply of gasoline, and five minutes later Grant called a halt of one minute to change right rear and left front tires.

Equipment of the Racers

The following table, showing the equipment of the various contesting cars as regards carbureters, magnetos, tires, etc., will be found interesting:

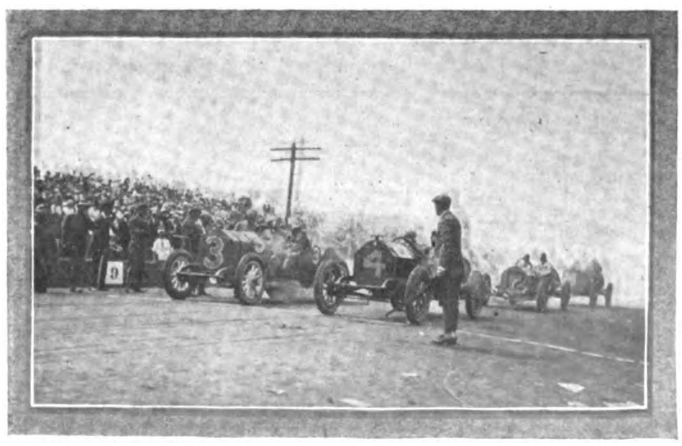
Worcester Dealers Ready for Show

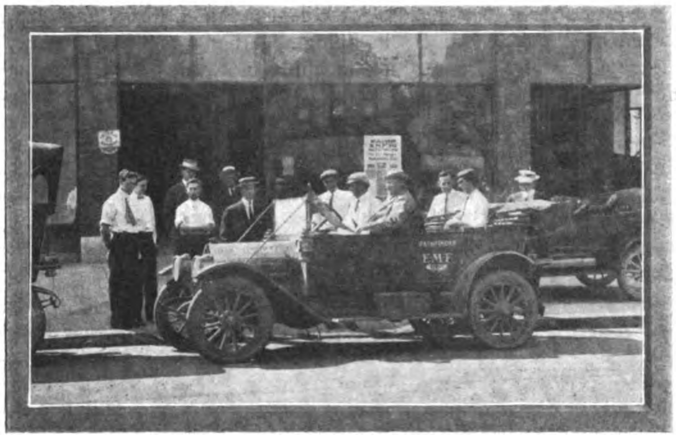
WORCESTER, MASS., Aug. 28—The second annual summer automobile show of the Worcester Licensed Dealers' Association will be held September 4, 5, 6 and 7, under two large tents at the New England fair grounds at Greendale in connection with the big annual agricultural event of this section of the country.

The show, besides embracing many of the leading 1912 models, will have spaces for exhibiting all sorts of accessories and supplies. The cars to be exhibited this year by the members of the Worcester Licensed Dealers' Association, will include Overland, Stanley Steamer, Winton, Cadillac, Maxwell, Rambler, Columbia, Thomas, Everett, Hudson, Elmore, National, Chalmers, E-M-F, Flanders, Mitchell, Stoddard-Dayton, White Gasoline, White Steamer, Velie, Knox, Franklin, Stearns and possibly the Chadwick, Packard, Buick and Regal, along with the following trucks: Gramm, White and Rapid.

The committee in charge of this year's automobile show is Henry J. Murch, chairman; LeRoy Leighton and William Carpenter.



The second line of Illinois Cup contenders, with the Kane County cars in the rear



Pilot Dai H. Lewis in the E-M-F pathfinder as he finished laying out the route for the second annual tour of the Automobile Club of Buffalo

Thirty in Buffalo Tour

BUFFALO, N. Y., Aug. 28—Present indications are that at least thirty cars will start in the Second Annual Reliability Tour, to be run September 6-9, under the auspices of the Automobile Club of Buffalo, for the Laurens Enos and other trophies.

The pathfinding work for the tour was completed on August 19th, under the direction of Dai H. Lewis. An E-M-F "30" was assigned as the official pathfinder and pilot car for the contest and was driven over the 800-mile course by George Meinzinger, another skillful driver of Glidden tour fame.

Following the precedent of last year, each day's run of 200 miles will start and finish in Buffalo. The technical end of the event will be in charge of the Contest Board.

The course thoroughly covers western New York from Lake Erie to Lake Ontario, and embodies elements most ideal for a reliability contest. The Laurens Enos trophy was won last year by Charles F. Monroe, Buffalo representative of the United States Motor Company, in a Maxwell. Mr. Monroe has entered four cars in this year's event to defend the cup.

Two-Day Meet at Brighton Beach

Two days of racing will be served up to the metropolitan public Saturday, Sept. 2, and Labor Day, Sept. 4, at Brighton Beach, under the direction of E. A. Moross. The program shows nine carded events for each day for cars eligible to compete in the "open" classes.

Besides the Moross string there will be several local entries and the sport promised is on a par with that offered at other meets under the auspices of the same promoter. The promised 24-hour race faded away Wednesday when it was announced by the Contest Board that application had been made by Guttenberg promoters for the Sept. 30 date. As this was the date tentatively selected for the long grind, the chances of holding the race are considered very slim.

Previously it had been announced that the promoter of the "twice-around-the-clock" event had secured nine entries and had the choice of two more.

Good Fields in Fernbank Road Races

CINCINNATI, O., Aug. 28—The Fernbank Dam Road Races to be held Sept. 9 as the culminating feature of the celebration marking the opening of the government dam below this city are attracting country-wide attention. During the Elgin meeting a committee from Cincinnati was busy canvassing the contestants for entries in the quartette of races to be run here.

It was announced that the committee had been successful to a certain degree and that the fields would be fair in each of the races. Southern Ohio is a big manufacturing field and entries from the local factories at Cincinnati and nearby have been promised. The cars will race under Class C limitations.

Next Week Most Important of Year

Next week will be one of the most important of the year in several particulars as applied to the automobile industry. In a sporting way there will be six race meetings, a road race, hill-climb and an endurance run, which is certainly the high-water mark of the year as far as contest work is concerned. But in a much wider sense, the conferences of the governing bodies of the industry which will be held in New York City are of vastly more import to the trade than the contests.

When the Automobile Board of Trade assembles, the roster of the Madison Square Garden show will be framed. Applications for membership in the organization will be received and acted upon and, after the conclusion of the meeting, the names of those who will exhibit at the show will be known.

The N. A. A. M. also holds one of the most momentous meetings of the season, at which the list of members will be increased and a number of details with regard to both the big National shows will be threshed out. The Manufacturers' Contest Association will meet to act upon the recommendations suggested to its membership at the recent Detroit session of the committee on rules.

The meetings of the A. B. of T. and the N. A. A. M. will be the last at which memberships can be granted this Fall so as to allow participation in the annual shows. The drawings for space will take place shortly afterward and those who wish to show at either of the exhibitions are hustling to get their applications in.

Besides these things the organizations will take up a vast mass of other detail work.

On the meeting of the M. C. A. depends the future of contests and it is quite apparent that there is a division of opinion as to a number of major matters in this class.

Stock Cars Only in Glidden Tour

The following official correction of the conditions under which the Glidden Tour will be run in October, has been issued by the Contest Board:

"Owing to a misunderstanding of the action of the Manufacturers' Contest Association, taken at the Detroit meeting, August 10 and 11, in reference to the registration of stock cars of private owners in the 1911 Glidden Tour, the supplementary regulations heretofore issued waiving registration requirements are hereby cancelled and registered stock cars only will be eligible to compete for the Glidden trophy and for the cash or plate prizes in the seven price divisions."

The following new entries have been received: J. R. Sandlin, Jasper, Fla., Cadillac; R. D. Drysdale, Jacksonville, Cadillac; Hoke Smith, Atlanta, Maxwell; Studebaker Corporation, three E-M-F's and the McIntyre Company, Auburn, Ind., McIntyre. With these additions the list now contains twenty-six entries.

Flyers Enter Old Orchard Meet

With the speedy Jackson racer that made such a good showing at Indianapolis Cobe has entered the open events to be decided at the beach meeting scheduled to take place at Old Orchard, Me., Sept. 4, 5 and 6. A Pope-Hartford car handled by Disbrow will also be featured on the sands. Besides these special racers it is expected that some creditable fields will face the starter in the class events. These will probably include a pair of Oaklands, three Camerons, an Atlas, two Buicks and three Velies. There may be some others as well.

Hartford to Have a Race Meet

HARTFORD, CONN., Aug. 28—The final day of the State Fair will see an automobile race program decided at Charter Oak Park. Ralph De Palma, with a big Simplex, is carded as the free-for-all star and in addition there will be a number of local entries in the class events.

Ohio Farmers Inspect Models

Columbus, O., Aug. 28—One entire building devoted to the display of automobiles was set aside by the Ohio State Board of Agriculture at the annual Ohio State Fair which is being held this week. It is the first time in the history of the fair that there has been such an extensive display of motor cars and the building was crowded.

The building was reserved for automobiles because of the demands of the farmers of the State that they be permitted to see the latest models of motor cars without leaving the fair grounds. Dealers in Central Ohio as well as factories soon realized the importance of the display and many applications for space were received by the board of agriculture. All of the exhibits were in place by 8 a. m., to-day.

The exhibits were arranged on platforms after the manner of automobile shows. Most of the exhibits are made by the dealers in Central Ohio, although a number of factories sent displays under the charge of their factory men. In all 67 cars were on exhibit which were distributed principally among the medium priced cars. One of the features of the show was the large exhibit of E-M-F cars. The Buick and Mitchell displays also attracted considerable attention. Other makes shown were the Elmore, Jackson, Overland, Zimmerman, Warren-Detroit, Abbott-Detroit, Maxwell, Columbia, Republic, Sampson, Brush, DeTamble, Liberty Brush, Ford, Hupmobile, Speedwell, Empire and others.

St. Louis to Hold Early Show

St. Louis, Aug. 28—Definite announcement of plans for the open air show to be held Oct. 2 to 7, has been made by the St. Louis Automobile Manufacturers and Dealers' Association. The association believes that in addition to this being the first time an open air show has been attempted on a large scale, it will also mark the first extensive display of 1912 models in this section.

The exhibit is to be held at Forest Park Highlands, an amusement resort, where there is available 60,000 square feet under roof. This is more than twice the space to be had in either the Coliseum or the Armory, where previous exhibits have been held and where there has always been complaint of lack room.

By a system of waterproof curtains all of the space under roof will be arranged so that it can be closed in if there is bad weather. The show will not be open to cars which are not represented in St. Louis by agents, but every St. Louis dealer, whether or not he is a member of the association in charge of the affair, will be taken care of by the committee, according to the announcement.

The show is to include separate displays of motor trucks and delivery wagons and of electric pleasure cars. Plans for decoration now under way provide for carrying out the idea of a forest scene, with tree trunks, bark and autumn leaves used in profusion.

Boston Figures on Race Meet

Boston, Mass., Aug. 28—President E. A. Gilmore of the Bay State A. A. has been in conference with a number of the well-known makers who have racing teams relative to a race meet at Readville this fall. The plans for a meet were first put up to President Gilmore some weeks ago by a prominent promoter, but the Bay State official had his experience a year ago with the Barney Oldfield campaigners, so he was not ready to allow anything else that was not in positive accordance with the contest rules.

Some of the club members thought a race meet would be a good thing and they have been talking it over. One of the members who was going to the Elgin races was asked to talk it over with some of the makers there and see what could be done. The Readville track is recognized as one of the safest in the country and there never has been a fatality there in a motor race mee.., caused by a couple one of them being an the track.

With the improvement of the road from Laporte to Sou... Bend the last link in the proposed automobile roadway from South Bend to Chicago would be completed.

Port Jefferson Climb Sept. 9

Far and away the most important hill-climb scheduled for this season in the vicinity of New York is the event to be held at Port Jefferson, L. I., Saturday, Sept. 9. Last year the climb proved to be both fast and spectacular and drew a big crowd and a typical entry list. This year the fields will probably be smaller in the stock events but in the special numbers the chances are that they will be larger.

Extensive preparations are being made to provide a well-balanced program with full technical supervision and administration.

Floral Parade in Iowa

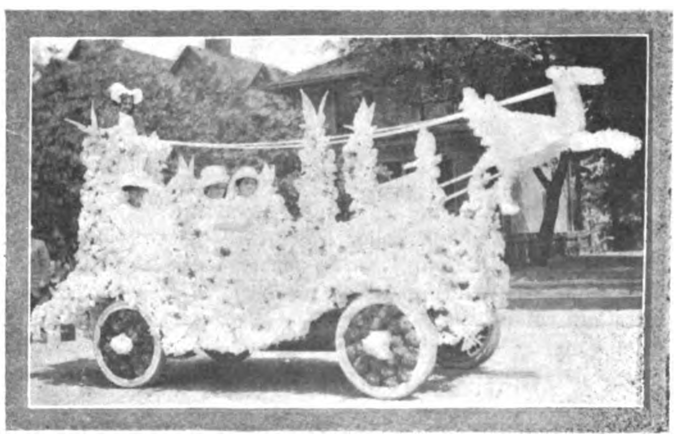
Des Moines, Ia., Aug. 28—Des Moines' second annual Iowa State Fair Automobile Show opened Saturday, with the first automobile parade ever held in Des Moines. Fifty cars, decorated from head lamps to tail lights, were entered in the floral pageant and it was one of the most beautiful sights ever seen in the city. Without doubt the floral parade will be made an annual feature. The local dealers were practically all represented in the parade.

A Cartercar driven by Mrs. Howard Schneider, of Newton, Iowa, was given first prize of $75 for the most beautifully decorated car, while second prize went to the Iowa Automobile Company's Staver car.

The automobile show promises to be one of the big features of the State fair. The space beneath the immense steel grandstand is being used for an exposition hall and 100 cars, representing every dealer in Des Moines, are being shown.

Ray Harroun and the Marmon "Wasp" have been booked as the attractions of the fair and during the week will be pitted in a speed contest against one of the two Wright air men who are at the fair.

Another racer who is here in daily exhibitions is Lou Heineman and his Case car.



Cartercar driven by Mrs. F. Schneider, of Newton, Iowa, winner of the first prize in the Des Moines floral parade

...re Apparatus

...line with a policy adopted ... equipment in the fire depart... ...y will purchase immediately a ...ked men, 250 feet of chemical ...l tank; a ladder truck carrying ...of ladders; a combination hose and ... a combination pump and hose apparatus to ...eet of hose and capable of pumping not less than ...llons of water a minute.

...ds are now under consideration for this apparatus and con...tracts will be let after the board has visited the various factories. At this time the fire department is using a squad wagon, a touring car in which the chief answers alarms and a truck for the fire alarm telegraph system.

In bidding for the proposed apparatus, each company was required to submit blue prints and specifications. The bids under consideration are:

Squad wagon: American La France Engine Co., Elmira, N. Y., $5,500; Knox Automobile Co., Springfield, Mass., $5,600; Webb Motor Co., St. Louis, $4,800; Victor Motor Co., Buffalo, N. Y., $4,185; Harder Truck Co., Chicago, $3,375; Thomas B. Jeffrey Co., Kenosha, Wis., $5,250; Meridian Auto Co., Indianapolis (Packard), $5,277.40; Central Automobile Co., Indianapolis (Grabowsky), $4,200, and Mais Motor Truck Co., Indianapolis, $4,750.

Pump and hose: American La France Engine Co., Elmira, N. Y., size 1, $8,500, size 2, $7,500; Knox Automobile Co., Springfield, Mass., $8,100; Robinson Fire Apparatus Co. St. Louis, $8,000; Webb Motor Co., St. Louis, size 1, $8,500, size 2 $7,450; Victor Motor Co., Buffalo, N. Y., $6,440.

Hose and chemical: American La France Engine Co., Elmira, N. Y., $5,500; Knox Automobile Co., Springfield, Mass., $5,600; Robinson Fire Apparatus Co., St. Louis, $5,500; Webb Motor Co., St. Louis, $5,000; Seagrave Co., Columbus, O., $5,000; Pope Hartford Motor Car Co., Hartford, Conn., $5,000; Victor Motor Co., Buffalo, N. Y., size 1, $4,665, size 2, $4,400; Harder Truck Co., Chicago, $3,375; Thomas B. Jeffrey Co., Kenosha, Wis., $5,500; Meridian Auto Co., Indianapolis (Packard), $5,277.40, and Mais Motor Truck Co., Indianapolis, $4,800.

Ladder truck: American La France Engine Co., Elmira, N. Y., $5,500; Knox Automobile Co., Springfield, Mass., $5,200; Robinson Fire Apparatus Co., St. Louis, $5,800; Webb Motor Co., St. Louis, $4,500; Seagrave Co., Columbus, O., $4,900; Victor Motor Co., Buffalo, N. Y., $4,690; Central Automobile Co. Indianapolis (Grabowsky), $3,800, and Mais Motor Truck Co., Indianapolis, $4,800.

News Notes from Kansas City

KANSAS CITY, Aug. 28—The Mitchell Lewis Motor Co. is to establish a branch in Kansas City, Aug. 31. The building is located at the southwest corner of Sixteenth and Grand streets, right in the heart of the motor row.

E. J. Kilborn, of the Mitchell factory, is to manage the branch.

The Kaw Valley Auto Co., who represented the Mitchell for three years, has not yet announced what line it would take in place of the Mitchell.

Kansas City is to have a Fall race meet, three days, commencing Sept. 2 and ending Labor Day. Many fast cars have been entered. K. L. Bernard, racing manager for the Automobile Club of this city, left Saturday to endeavor to obtain some of the Elgin contestants.

Montreal Longs for More Speed

MONTREAL, Aug. 28—A movement to establish certain reforms which mean much to automobile users and dealers is being advocated quietly and will probably take definite shape before the leaves are off the trees. The prime movers hope to see their aims accomplished before the opening of the summer season of 1912. The project has two principal aims. The first, to see the speed limit law for the City of Montreal made to conform with modern ideas and conditions, and second, to have the mountain roads opened to automobiles during certain hours of the day.

F. G. Pennal and Frank Stockwell are the prime movers. If their plans mature, either a new automobile association will see light in this city or The Automobile Dealers' Association, which was brought into being at the time of the motor show last spring, will be galvanized into activity and will take the matter up.

The present speed limit in Montreal is approximately 9 miles an hour.

Drivers of automobiles in Montreal have another vigorous kick coming against existing conditions, in the manner in which the law is enforced. Mr. Stockwell says that speeding at the rate of 20 miles an hour on crowded thoroughfares like St. James street, where anything above 6 miles an hour involves a certain amount of danger, is ignored, simply because the Provincial Government entrusted with the enforcement of the law confines its attentions to boulevards, like Park avenue north.

For hill climbing also Mr. Stockwell says a low speed is undesirable. A car climbing a hill such as Beaver Hall Hill on top gear with small noise, little gas exhaust, causes infinitely less annoyance to pedestrians and householders than a car running up on low gear, emitting smoke and noises, to the irritation of all beholders.

In Toronto, the speed limit is twice as high as it is here, and in Detroit and New York it is higher still. The fact that an automobile may be handled with a much greater degree of certainty and speed than a horse, makes these limits practical in cities where the traffic is at least as congested as it is in Montreal.

Mr. Pennal is at present engaged in collecting data from all

Camping Car for duPont

Senator T. Coleman duPont, of Delaware, who recently created a sensation in the motoring world with the announcement of his determination to build a public highway running due north and south through his entire home State, is going ahead with his project.

Col. duPont's purpose is to keep in personal touch with the project and to this end has accepted delivery of a Stoddard-Dayton camping car built under his own plans.

The car is of 45-horsepower on 115 inches wheelbase, with a body specially constructed and so laid out that it has sufficient length inside to accommodate a hair mattress 6 feet long. There are two lockers about 6 inches wide, which run the length of

Rubber Company Enters Tire Field

AKRON, O., Aug. 28—The Miller Rubber Co., which recently added tires to the list of its products, has purchased five and a half acres of additional land near the factory in South Akron, for the purpose of making extensions. Previous to entering the pneumatic tire field, the Miller Rubber Co. confined its activities solely to rubber sundries.

the body on each side, affording packing space for supplies. The top is permanent, with a slat rack on the under side holding four vulcanized fibre provision boxes which are strapped into place over the rack. There is also a rack in the top for taking care of drawings, plans, etc., and arranged on the top of the body above this is a slat rack with an iron railing of sufficient size to carry four extra tires, which are tightly strapped to the rack.

Col. duPont's gift to the State of Delaware is a highway 103 miles long, from 100 feet to 200 feet wide, running from one end of the State of Delaware to the other. In building this road he is personally determined to see that it is built right, and he is going to superintend the construction of it himself. It will cost $1,500,000.

Six Perfect in Lake Tahoe Run

SAN FRANCISCO, CAL., Aug. 29.—Six cars out of fifteen finished with perfect scores to-day in second annual endurance run from this city to Lake Tahoe and return. The distance is 520 miles, a goodly part of which is through the Sierra Nevadas, rising 7,000 feet, with many very steep grades, and badly twisted roads. The cars that survived the ordeal were: American 50, Buick 26, Buick 30, Flanders 20, Franklin 18, runabout, and Winton Six.

The run proved to be unusually severe upon tires owing to heat of the valleys and severe grades over rough mountain roads. Many of the cars suffered a large number of punctures and running time was so fast that they had to use a good deal of speed to keep up with schedule.

Last year contestants complained that schedule was too slow but this year there was no complaint on this score. The schedule averaged more than 20 miles an hour on the level and over 15 miles through mountains.

Firestone Moves into New Factory

AKRON, O., Aug. 28—The Firestone Tire and Rubber Co. is removing from its old to the new factory in South Akron. The Firestone Co., compelled some time ago to find more room, decided to build an entirely new factory instead of adding to its old one. About half the removal has been accomplished.

The old plant will be devoted to the manufacture of rims. One of the unique features of the new office arrangement is a complete restaurant, smoking room and dining room for office employees, with accommodations for 400 persons and what is considered the largest refrigerator capacity in the city. The management has also a plan, not yet formally announced, for supplying hot soup and other substantials to employees of the factory.

Harking Back a Decade

THE *Automobile Blue Book* first made its appearance ten years ago this week. It was a sort of compendium or compilation of all sorts of information likely to be of use to automobilists and its present mission as a road guide was only promised in a limited degree.

As an indication of the great strides the automobile was making at the time it was noted that the manufacture of the electric automobile and the steam automobile made by the American Bicycle Company had been transferred respectively to the Waverley factory at Indianapolis and to the Toledo factory at Toledo, Ohio.

Henri Fournier and "Tod" Sloan arrived in New York to establish an American agency for the Mors.

A note from Homburg stated that King Edward VII had two automobiles with him. One of these was equipped with a plate of glass at the back to keep off the dust.

The Daimler company was said to be busy experimenting with a car to be driven partially by benzine and partly by electricity.

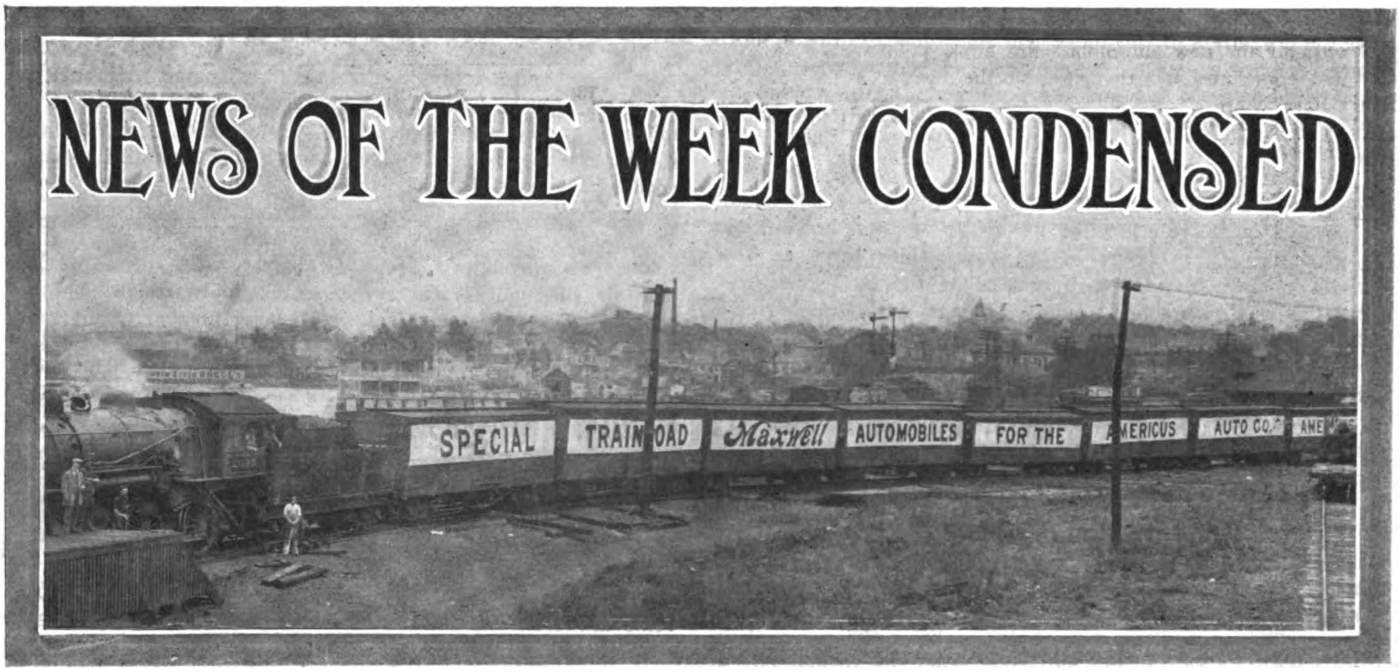
A British correspondent of *The Motor Review* advises automobilists to avoid the use of goggles. His reasoning is as follows: The wearing of goggles presupposes speed and in the eyes of the police raises the presumption of illegal speed. Therefore, in order to avoid even the appearance of evil go as fast as you like but leave off the goggles.

For the first time an automobile was named as co-respondent in a divorce case. A resident of Passaic, N. J., filed a complaint upon which the onus of "breaking up the happiest home in the world" was laid at the door of a Newark man's car.

The 500-mile endurance run to Buffalo, scheduled for September 9-14, 1901, had seventy-six entries on August 31.

Announcement was made that the Chicago Automobile Club, an embryonic organization, had decided to build a clubhouse.

The *Auto Era*, house organ of the Winton Motor Carriage Company and pioneer in that field, made its début.



AMERICUS, GA.—Right in the heart of the so-called dull season, a special train of nine cars loaded with Maxwell automobiles is on its way from the factory to this place consigned to the Americus Automobile Company. The cars are all equipped with the special 60-inch tread which is required for operation on Southern roads. The extra four inches of width is always included in Maxwell cars destined for the Southern market.

PLAINFIELD, N. J.—The Spicer Manufacturing Company has announced the installation of an electric vehicle charging station and service department.

BOSTON, MASS.—The Stutz car is now represented in Boston, an agency for it having been opened last week by the Empire Motor Car Company as an addition to its line.

INDIANAPOLIS, IND.—The Indiana Four States Tour was such a success that the automobile builders of this State have organized a State society. This took place recently at a picnic to celebrate the 1,500 miles trade boosters' tour.

BOSTON, MASS.—George Parker, who for a long time was identified with J. H. MacAlman, selling Columbia and Stearns cars in the Hub, has gone over to the commercial field and he is now sales manager of the Mack Motor Truck Company in this city.

LANSING, MICH.—Since the first of the year Secretary of State Martindale has collected automobile license fees amounting to $93,000, which is an increase of $20,000 over last year. The number plates for next year will be black numerals on an orange background.

PORTLAND, ORE.—Preparations for a dash into the Arctic zone are being made upon the Abbott-Detroit "Bull-Dog" which is now in this city. The car will be fitted with hickory runners on the front wheels and metal studded tires on the driving wheels. The car has done about 32,000 miles so far.

RACINE, WIS.—The automobile department of the J. I. Case Threshing Machine Co., Racine, Wis., is making exhaustive tests of a new type of rear axle which is being manufactured by the Green Engineering Co., of Racine, owner of the patent rights. If found entirely satisfactory the axle will be incorporated in all 1912 Case cars, it is stated.

LANSING, MICH.—T. Earle Jarrard, who for the last five years has been connected with the Reo Motor Car Company and the R. M. Owen Company, will leave the city in a short time to accept a position with the Apperson Brothers Automobile Company, of Kokomo, Ind. Mr. Jarrard will be assistant to Elmer Apperson, who is president and general manager of the concern.

AKRON, O.—H. J. Woodard, for some time manager of the New York store of the Diamond Rubber Co., has resigned and taken a position as sales manager with the Century Tire Co., of New York. He is succeeded in the Diamond branch by N. E. Oliver, who has been manager for Buffalo, and who will still oversee the activities at Buffalo in addition to his New York responsibility. A. J. Henry, of Akron, will assist Mr. Oliver in the conduct of the Buffalo branch.

BOSTON, MASS.—Manager C. P. Rockwell of the Boston branch announced, following his visit to the conference at the Rambler factory last week of the branch managers, that arrangements had been completed to erect a new home for the Hub branch on Commonwealth avenue in the near future. The Boston branch now has one of the finest salesrooms in Boston, but the officials of the Thomas B. Jeffrey Company want to have the repair department and salesrooms in the one building.

FINDLAY, O.—The Norwalk Motor Car Company, Norwalk, Ohio, has been adjudged a bankrupt in the United States court at Toledo, Judge Killets sitting. A. J. Schur, of Cleveland, an attorney, has been appointed receiver with bond at $20,000. The plant will be operated by the receiver. The proceedings were brought by the Diamond Rubber Company, of New York; the Pennsylvania Rubber and Supply Company, of Cleveland, and the Cross-Gilcrist Advertising Co., of Cleveland.

LANSING, MICH.—The Olds Motor Works is about to spend $215,000 for the erection of a modern factory building replete with fine equipment. Upon its completion 500 men will be added to the present force, making the total number of employees about 1,800. The W. E. Wood Construction Company, of Detroit, has been given the contract. The structure will be built of brick with reinforced concrete foundations and steel sash throughout. It is expected the structure will be finished in four months.

LOUISVILLE, KY.—Paducah motorists are in hearty accord for the establishment of a model highway from Louisville to Paducah, as suggested by Rush C. Watkins, president of the Louisville Automobile Club. The Paducah automobile owners have reorganized their association and will assist in securing improved roads in Western Kentucky. It has been proposed to improve the road from Paducah to Hopkinsville, where the Jefferson Davis Way can be tapped. The road from Louisville to Paducah is at present seldom used because of the poor condition of the highway.

CINCINNATI—Great interest attended the appearance of the new automobile fire engine, just completed for the city, by the Ahrens-Fox Co. For the test it was loaded with fourteen men, and ballast equal to its complement of hose.

CINCINNATI—President Pratt of the Ohio Motor Co. left yesterday on a trip to Canada via Cleveland, Buffalo and Toronto and will be absent about two weeks. He has named The Federal Motor Car Co. as representative of the Ohio company for Pittsburgh and Western Pennsylvania.

COLUMBUS, O.—The contract for supplying 40,000 or more sets of number plates to the Ohio State Automobile Department for the year 1912 has been awarded to the Scioto Sign Company, of Kenton, O., at 23 1-2 cents per set. The 1912 tags will be in green on a white background of enamel. The tags are to be numbered consecutively and the first delivery is to be made November 1. The tags are to contain the word "Ohio" and the figures 1912.

LOS ANGELES—Southern California has a telephone service that is unique, being a system of roadside stations for the use of automobile drivers in case of emergency. For instance, in case of a breakdown, it will not be necessary to walk for miles to the nearest telephone toll station, as the new system provides a portable telephone outfit for the car of each member. All that is required is to "plug in" at one of the numerous telephone poles which have been converted into emergency stations, and 'phone to the nearest garage.

AKRON, O.—The Goodyear Tire & Rubber Co. is preparing to have a storage lake, or pond, in East Akron, as a source of water supply when other sources are interfered with, so that water famines or the stoppage of regular sources of supply may not at any time necessitate the closing of their factory. Recently the company purchased eighteen acres of ground in the vicinity of Kelly avenue, and a dam is being built across the lower end of the property, so that about six feet of water will be backed up as far as the line of the property the company has acquired.

Automobile Incorporations

AUTOMOBILES AND PARTS

ATLANTIC CITY, N. J.—Atlantic Perfected Motor Co.; capital, $300,000; to manufacture automobiles and engines. Incorporators: Frank Brown, Thos. Kilcourse, Samuel S. Phoebus, John S. Ingram.

AUGUSTA, ME.—Autocart Co., capital, $15,000; to make automobiles and trucks. Incorporators: Chas. H. O'Brien, Lewis A. Burleigh.

BROOKLYN, N. Y.—Mohr Auto Co.: capital, $25,000; to manufacture automobiles and parts. Incorporators: Henry Mohr, Max Keve, Charles Goldstein.

CHICAGO, ILL.—Automobile Construction Co.; capital, $27,000; to manufacture automobiles. Incorporators: Albert T. Graham, H. M. Wells, Wm. E. Fuller, Geo. F. Mulligan.

CHICAGO, ILL.—Simplex Auto-Cranker Co.; capital, $100,000; to manufacture automobiles, supplies and machinery. Incorporators: Edwin A. Gardner, Ignatius F. Halton, Willard Patrick, P. W. Rosenstone.

CINCINNATI, OHIO.—Rambler Motor Car Co. of Cincinnati; capital, $25,000; to deal in automobiles and supplies. Incorporators: Geo. H. Jung, F. D. Ratterman, Charles Reed, W. H. Kaufman, Walter C. Reed.

HOPKINSVILLE, KY.—Caye-Jones Motor Co., capital, $10,000; to make automobiles.

JERSEY CITY, N. J.—Studebaker Corp. of America; capital, $100,000; to manufacture automobiles. Incorporators: M. Gregg Latimer, John B. Marsh, John R. Turner.

LOUISVILLE, KY.—Wilder Motor Car Co.; capital, $5,000; to sell, repair and rent automobiles.

NEW YORK, N. Y.—Bergdoll Motor Car Co.; to manufacture automobiles; capital, $10,000.

PONTIAC, MICH.—General Motors Co.; to manufacture electric trucks.

RICHMOND, VA.—Virginian Sales Co.; to sell Virginian automobiles. Incorporators: Louis Hartig, Louis Hartig, Jr.

TOLEDO, OHIO.—Toledo Annealing Charging Truck Co.; capital, $10,000; to make motor trucks. Incorporators: John G. Blum, M. G. Blum, Joseph M. Rutherford, Edward F. Abbey, Racheal E. Rutherford.

AUTOMOBILE GARAGES, ACCESSORIES, ETC.

CAMDEN, N. J.—American Tire Protector Co.; capital, $1,000,000; to manufacture tire protectors and punctureproof tires. Incorporators: Robert B. Watson, John P. Donahue, Robert St. John.

DETROIT, MICH.—Climax Motor Parts Co.; capital, $50,000; to manufacture accessories.

HOBOKEN. N. J.—Imperial Garage Co.; capital, $10.000.

JERSEY CITY, N. J.—The Marquette Co.; capital, $10,000; to manufacture motors. Incorporators: S. B. Mantz, H. A. Black, John R. Turner.

MILWAUKEE, WIS.—Motor Convenience Co.; capital, $30,000; to manufacture various accessories. Incorporators: Charles F. P. Pullen, George D. Londerbeck, I. W. Davis.

NEW YORK, N. Y.—Consolidated Lubricants Co.; capital, $25,000; to make and deal in lubricating oils, greases, etc. Incorporators: Arthur R. Pardington, Warren L. Sawyer, Jos. N. Patch.

NEW YORK, N. Y.—United Rubber Co.; capital, $100,000; to manufacture rubber goods. Incorporators: Ada A. Sands, Eva C. Baker, Frank B. Vermilya.

NEW YORK, N. Y.—Automatic Fender Co. of America; capital, $1,000,000; to manufacture automobile fenders. Incorporators: Wm. M. McGuirk, Saul S. Myers, Wm. E. Lowther.

SCHENECTADY, N. Y.—Union Lubricating Co.; capital, $25,000; to manufacture and deal in lubricating oils. Incorporators: J. W. Nagle, Edward H. Robinson, M. C. Cahill.

SHAWANO, WIS.—Frogner Auto Co.; capital, $5,000; to conduct a general garage business. Incorporators: A. G. Frogner, C. E. Dunn, E. M. Williams.

COLUMBUS, O.—The Ohio State Highway Department at Columbus, O., with the assistance of the Ohio Good Roads Federation gave a roads exhibition at the Ohio State Fair during the week of August 28 to September 1. The highway department at Washington, D. C., sent displays and models relating to the subject of good roads construction and the exhibits were complete in every respect.

A New Ball-Bearing

Joseph Schaeffers, one of the early members of the S. A. E., has returned from his European trip, bringing with him the sole U. S. agency of one of the well-known German ball bearings, the H. C. B. bearing, made by the H. Hollmann Company, in Burgsolms, Lahn.

The bearings have a solid, patented, two-part, wire-stitched cage, as shown in Fig. 2, or a sheet-steel retainer, or one consisting of two pieces only and protected by patents, as shown in Fig. 3. Among the particular features of these bearings two types for combined radial and thrust load may be mentioned. Fig. 4 shows a cross-section. These types have an angularity of contact between balls and raceways, this angularity being 30 degrees in the one, and 45 degrees in the other type, and these types are particularly well adopted for taking the combined loads of bevel gear shafts.

For all places where warping or sagging is liable to bring the shaft and the housing of the ball bearing out of alignment, a new and patented type of bearing has been placed upon the market. Fig. 1 shows a cross-section. The H. C. B. bearings are made of the finest German chrome tool steel from the Becker Steel Works, and are hardened and inspected, ground and inspected, assembled and inspected with care and thoroughness.

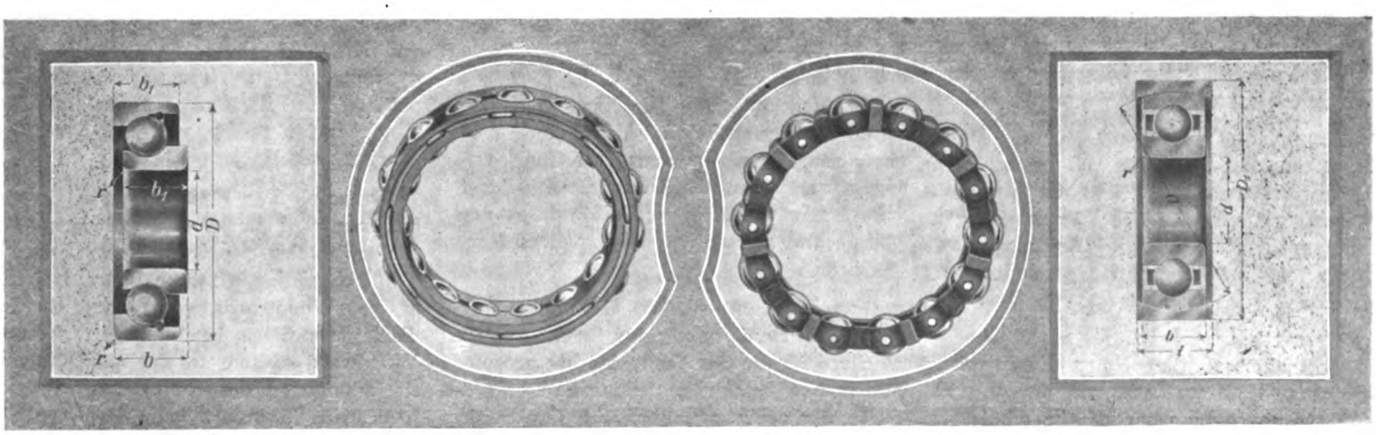


Fig. 1—Cross-section of anti-disalignment H. C. B. bearing. Fig. 2—Wire-stitched cage type of ball bearing. Fig. 3—Two-piece steel-cage bearing. Fig. 4—Cross-section of ball bearing for radial and thrust loads combined

Stearns 5-ton truck purchased by the House of Correction, Chicago, for the transportation of prisoners

BOSTON, MASS.—William Blanchard has been appointed sales manager of the Lenox Motor Car Company here, having succeeded Frank V. Cooke.

WASHINGTON, D. C.—The Commercial Automobile & Supply Co. has taken the Flanders electric agency and will handle it in connection with the E-M-F and Flanders.

PHILADELPHIA—"The Tire Shop" has removed from 1326 Vine street to larger and more suitable quarters at 225 North Broad street, in the heart of Automobile Row. David Scannell is the proprietor.

ZANESVILLE, O.—Edward B. Raemer, formerly advertising manager for the Flash Manufacturing Company, is now engaged as manager of the Valley Motor Company, of this city, handling the Overland line of cars.

ROCHESTER, N. Y.—The Selden Motor Vehicle Company announces the appointment of James Joyce as manager of sales and that of Fred A. Law as head of its engineering and production departments.

WASHINGTON, D. C.—The Carpenter Automobile Co. has sold its garage at Seventeenth and U streets, N. W., to Francis P. Blair, who will take possession on September 1. Extensive improvements will be made.

CHICOPEE FALLS, MASS.—W. Bonsor, late of the Packard Motor Car Company, is now associated with the Stevens-Duryea Company in the production department of the factory in the capacity of supervisor of parts.

ROCHESTER, N. Y.—F. M. Hoblitt, general manager of the Rector Engineering Company, of New York, will devote part of his time as manager of the wholesale department of the Selden Motor Vehicle Company.

BARABOO, WIS.—The Gollmar Garage is erecting a fine new garage building to include a large repair shop. It will cost about $8,000 and will be one of the most modern garages in the smaller cities of Wisconsin

BOSTON, MASS.—Willard M. Jenkins, who has handled the Mitchell line in the Hub ever since it was introduced there, has added the Abbott-Detroit to his line, and may probably also take on the Krit.

ITHACA, N. Y.—The J. B. Lang Engine and Garage Company has completed a fireproof garage 75 by 200 feet in which no pillars are used. Separate stalls that can be securely locked are provided for the storage of customers' cars.

CHICAGO—In addition to offices just opened at Minneapolis, Kansas City and Indianapolis, the Stewart & Clark Manufacturing Company is opening a new office at Cleveland, Ohio, at 1849 Euclid avenue, in charge of H. A. Ungar.

BOSTON, MASS.—The Abbott Motor Company, of Detroit, Mich., has just consummated a large contract with the W. M. Jenkins & Company, 288 Columbus avenue, Boston, Mass., as distributors for New England for the Abbott-Detroit line.

MILWAUKEE, WIS.—The Lion 40 has secured representation in Milwaukee, Wis., the agency being in charge of Charles E. Gavin and John G. Koerner, with headquarters in the Majestic building. A new garage and salesroom is being erected for the firm.

DETROIT, MICH.—Robert C. Winlow, formerly assistant purchasing agent of the Packard Motor Car Company, has accepted and is now occupying the position of general purchasing agent of the Grabowsky Power Wagon Company, 1735 Mt. Elliott Avenue, Detroit, Mich.

HILLSBORO, O.—R. D. Currie has recently opened a garage and repair shop at the intersection of West and Walnut streets, Hillsboro, O. The establishment contains 11,392 square feet of floor space and is one of the largest in Hillsboro.

BALTIMORE, MD.—H. S. Block, formerly connected with Waterman Brothers' Company, of California, has accepted the position as manager of the local branch of the Stoddard-Dayton Automobile Company. Leo H. Shaab, formerly manager, will be associated with the sales end of the local business.

PONTIAC, MICH.—R. McCracken, who has for some time been in Pontiac, reorganizing the office, factory and accounting system of the General Motors plants, and at the same time acting as comptroller, will leave shortly for Detroit, where he will take an important position in the office of the General Motors Company.

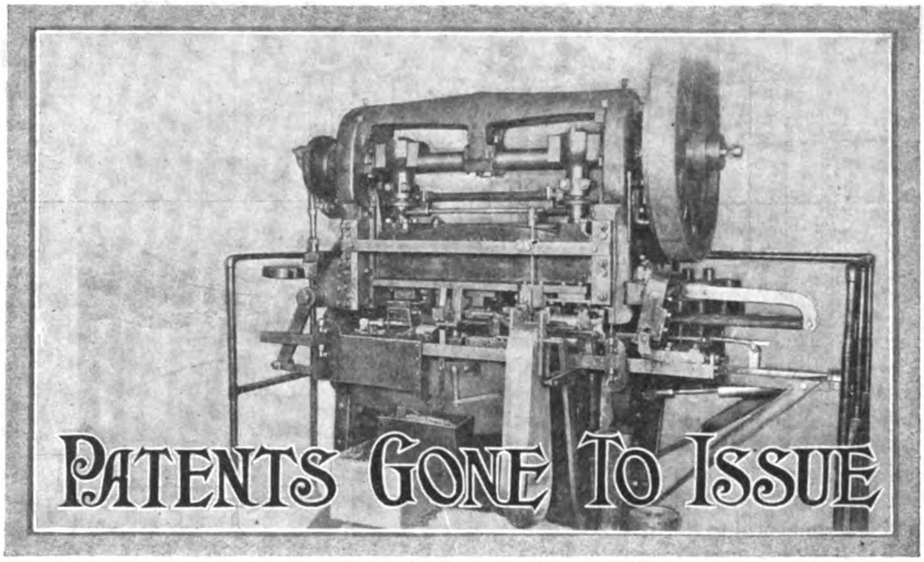
LANSING, MICH.—Arrangements have just been consummated whereby the General Motors Company will acquire ownership in a company manufacturing electric trucks. An entirely new manufacturing organization will be built up with John M. Lansden, formerly president of the Lansden Company, of Newark, N. J.

FLINT, MICH.—Before the close of the month it is expected the new plant of the Mason Motor Company will be in operation, according to Arthur Mason, general manager of the concern. Though the company has been organized only about three weeks, half of the machinery to be used in the manufacture of engines has been installed.

MILWAUKEE, WIS.—The Bates-Odenbrett Auto Co., 503-507 Broadway, has been appointed State distributor for the White pleasure and commercial cars and the Abbott-Detroit line. The Overland line has been discontinued and will be represented by the Motor Car Sales Co., 136 Oneida street, Milwaukee, which will also represent the Marion.

WASHINGTON, D. C.—The Marion Motor Car Company has leased the salesroom at 1333 Fourteenth street, N. W., now occupied by the Wilson Co., agents for the Cole and Krit. The latter will have temporary quarters with the Terminal Taxicab Co., pending the selection of a new salesroom. The Marion company will handle the Marion and American.

DETROIT.—The Emil Grossman Company has removed its Red Head spark plug factory to this city from New York. The plant, consisting of three floors, is located at 844 Woodward avenue, and the local display room has been removed from 874 Woodward avenue to the above location. As announced the Emil Grossman Company will fill orders from its New York, Chicago and Detroit quarters on an equal basis.



SPRING TIRE—A combination of two rims with a series of springs placed between them.

4. This spring tire (Fig. 1) is composed of two rims, the space between which is enclosed by means of plates arranged oppositely. Between the rims S-shaped springs are located; also stops carried on rings which are mounted on the plates mentioned. The stops permit a movement into the rings and out of engagement with the springs, arms being provided which project from the rings through the side plates located in the space between the two rims and which are movable to effect circumferential movement of the rings and the stops carried by them.

No. 1,000,796—To Jacob Whitfield Graham, Raritan, N. J. Granted August 15, 1911; filed November 8, 1910.

FENDER—Being a new form of bumpers to be used on automobiles.

4. The patent covers the securing to an automobile of a number of brackets by means of pivots, means for holding the brackets in their adjusted positions, clamping members adjustably secured to the brackets and springs secured intermediate their ends to the brackets and at their (the springs') ends movably secured to a buffer bar, with resilient cushioning members disposed intermediate of the clamping members and buffer bar.

No. 1,000,668—To Edwin K. Conover, Paterson, N. J. Granted August 15, 1911; filed June 16, 1910.

INTERNAL COMBUSTION GAS TURBINE—Combining the rotary and reciprocating principle.

1. This patent relates to an engine comprising a rotor with radially disposed, open-ended spiral passages, a driving shaft being rigidly fixed to the rotor and an elongated cylinder within the rotor, extending in line with the drive shaft. The cylinder has a series of passages arranged in line with those of the rotor and a piston rod is slidably mounted on the cylinder, a plurality of piston heads being mounted separately on the piston rod. An inlet port with a valve to control it is provided in the cylinder, and the inlet end of the cylinder and the space between the piston heads are connected by means of a valve-controlled passage. A spark plug is so situated as to be able to ignite an explosive mixture in the space between the piston heads, in timed relation with the piston rod movements. The piston rod and driving shaft are connected through a mechanism which serves to reciprocate the piston rod in timed relation with the rotation of the shaft.

No. 1,000,882—To Edwin Atwell, Baltimore, Md. Granted August 15, 1911; filed August 4, 1910.

ODOMETER—A mile meter of the type which is directly connected to the hub.

2. The register which is shown in Fig. 3 is supported by the hub and a shaft, an eccentric being mounted eccentrically in the wheel hub, where is also mounted a ratchet wheel with which a bevel gear is concentrically mounted. An eccentric link is mounted in the hub and connected to a pawl carrier, having a pawl and being mounted concentrically with the ratchet wheel. The bevel gear above mentioned meshes with another bevel gear connected to the register, a gear on the register shaft engaging loosely with the bevel gear and another gear secured to the end of the axle.

No. 1,000,861—To Curtis Hussey Veeder, Hartford, Conn., assignor to the Veeder Manufacturing Company. Granted August 15, 1911; filed January 12, 1911.

SPANNER-WRENCH—This is descriptive of a wrench with one jaw having a convexly curved face and the other fitted for various sizes of nuts.

5. By this patent is covered a wrench for nuts of different sizes. The spanner end has a convexly curved jaw apt to engage a nut facet, the other jaw having several plane grip faces each capable of engaging a certain size of nut upon a facet diametrically opposite to the nut facet engaged by the curved jaw. Each of the grip faces of the second jaw is parallel to the tangent of the first (curved) jaw at the point of engagement, thereby permitting of securely gripping the nut. The wrench jaws are so proportioned that the spanner may rotate in one direction.

No. 999,968—to Edwin A. Denham, assignor to the Erie Wrench Co., of New York, N. Y.; granted August 8, 1911; filed September 10, 1910.

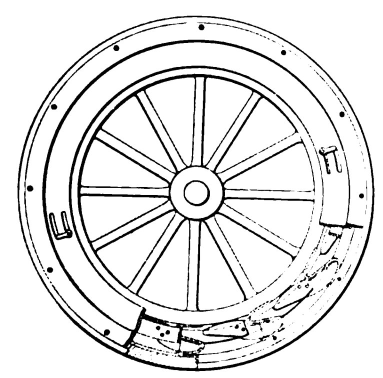


Fig. 1—Illustrating the spring-tire patented by J. W. Graham

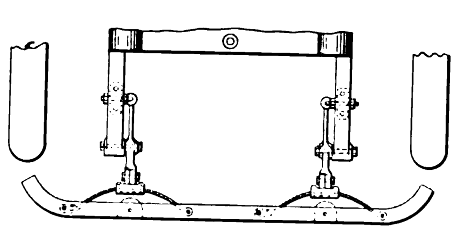

Fig. 2—Showing the new Conover automobile safety fender

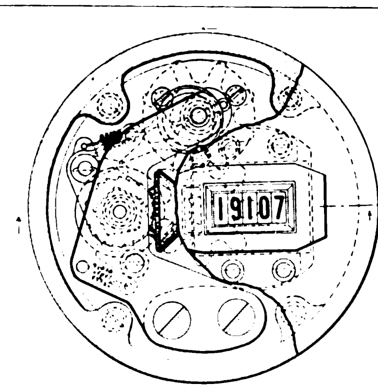

Fig. 3—Mechanism of the latest type of Veeder odometer

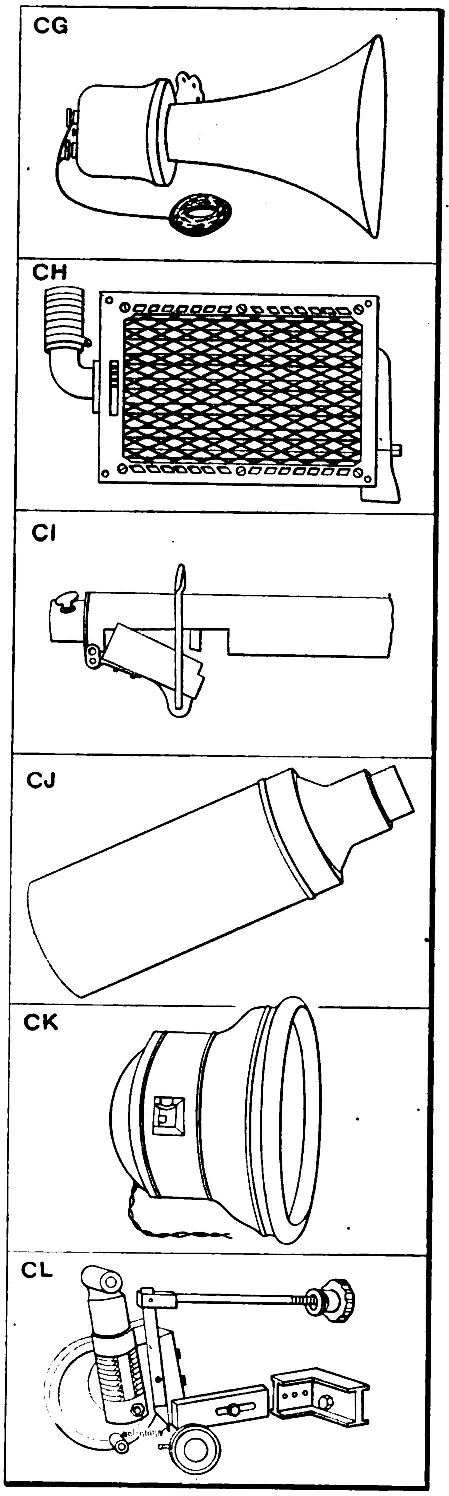
Seen in the Show Window

STRENGTH of sound is the chief claim made for the Typhoon electric horn, which is illustrated at CG. The type shown consists of a motor enclosed in the short cylindrical part of the horn and which serves to excite the sound waves in the air. The sound on its travel out of the device is considerably intensified by the horn proper or megaphone, as it might be called, which is about three times as long as the motor portion and serves to strengthen considerably the sound produced by the motor. This latter is connected to a battery, either a storage battery or a set of dry cells, and operated by pressing a button on the steering wheel or wherever the automobilist finds it convenient to install it. The interior members of the horn are of such material as will warrant longevity on their part, and the "megaphone" is made of strong brass, thus making for a pleasing appearance. The signal is the product of the Typhoon Signal Company, whose factory is located at 1389 Milwaukee avenue, Chicago, Ill.

COMPLAINT of car owners is not unfrequently aroused by the cold temperature obtaining in the automobile in Wintertime, and to do away with this troublesome state of things the Al-Ton car heater, shown at CH, will be a good thing to place in an automobile. This heater utilizes the waste heat of the exhaust which by the use of a by-pass valve is led through several pipes located under the metal net work shown in the illustration. After passing through the heater, the exhaust is conducted to the muffler in the usual way, and since the construction of the apparatus obstructs the flow of the gases in no way, no back pressure is caused by the use of the heater. The Al-Ton Motor Accessory Company, South and High streets, Akron, Ohio, makes this device.

HEATED gases expand in exhausting and thereby produce a noise, especially if the expansion of the gases is handicapped in any way. To reduce the noise caused by the expanding exhaust gases silencers are used, and it stands to reason that if the gases instead of through the muffler are passed through a suitable pipe or whistle a very efficacious signal may be produced in this way. At CI a whistle of this type is shown which is connected up to the exhaust lead, but normally closed by a valve. If the valve is opened and the gases allowed to enter the whistle a rich, mellow note is produced which is easily heard for a mile ahead of the car. The Eagle whistle is made by the Eagle Whistle Company, of Boston, Mass.



CG—Typhoon horn, operated electrically from the dash
CH—Al-Ton car heater used gases flowing to muffler
CI—Eagle whistle utilizing exhaust to produce signal
CJ—Vaco bottle keeps liquids hot or cold at will
CK—Columbus electric headlight comes in brass or black finish
CL—M. & L. crank-operated reciprocating tire pump

EVERYTHING which makes for comfort in touring is welcomed by automobilists, and a very useful accessory which serves this end is shown at CJ, this being the Vaco bottle, made by the Caloris Company, Philadelphia, Pa., for the purpose of keeping liquids warm or cold for a considerable length of time. The bottle which is transported in a metal container has a double wall of thick glass, the space between the two walls being hermetically sealed after the air has been exhausted from it. The practically empty space prevents heat from passing through it either into or out of the bottle, so that it is capable of keeping liquids ice cold for three days or boiling hot for twenty-four hours, if the bottle is stopped up tightly by the cork. In addition to these features, the bottle may be used to keep milk sweet for any length of time without the use of ice or any cooling substance.

LAMPS, especially headlights, are now very frequently of the electric type, owing to the great illuminating power and cleanliness of this class of lighting equipment, and the illustration CK shows a well-known standard type, this being the product of the Columbus Auto Brass Company, Columbus, Ohio. The lamp is made of brass throughout, with a reflector provided on the inside, the inner space of the lamp being closed up by a heavy glass plate. The lamp here illustrated is a headlight, and while the regularly furnished type is finished in brass, a black effect may also be secured if the purchaser so desires.

LONGEVITY of tires depends upon their being fully inflated at all times, and while the old style of hand pump is something of an inconvenience the M. & L. tire pump, seen at CL, does away with the bulk of the trouble arising from the operation of such a pump. The M. & L., which is furnished with 12 feet of high-pressure hose and all necessary connections and is guaranteed for a year, may be used to pump the tires up to 90 pounds pressure within three minutes time. The operation is simple: the hose is connected to the tire valve and the hand wheel of the pump turned. A gauge attached to the pump indicates the pressure in the tire. The pump may be attached to any type of automobile, and is bound to operate, since the handwheel through a crankshaft reciprocates the plunger in the pump cylinder which is air cooled by means of cannelations on its surface. This pump is made and sold by the Migeot Machine Company, of 333 North Fourth street, Philadelphia, Pa.

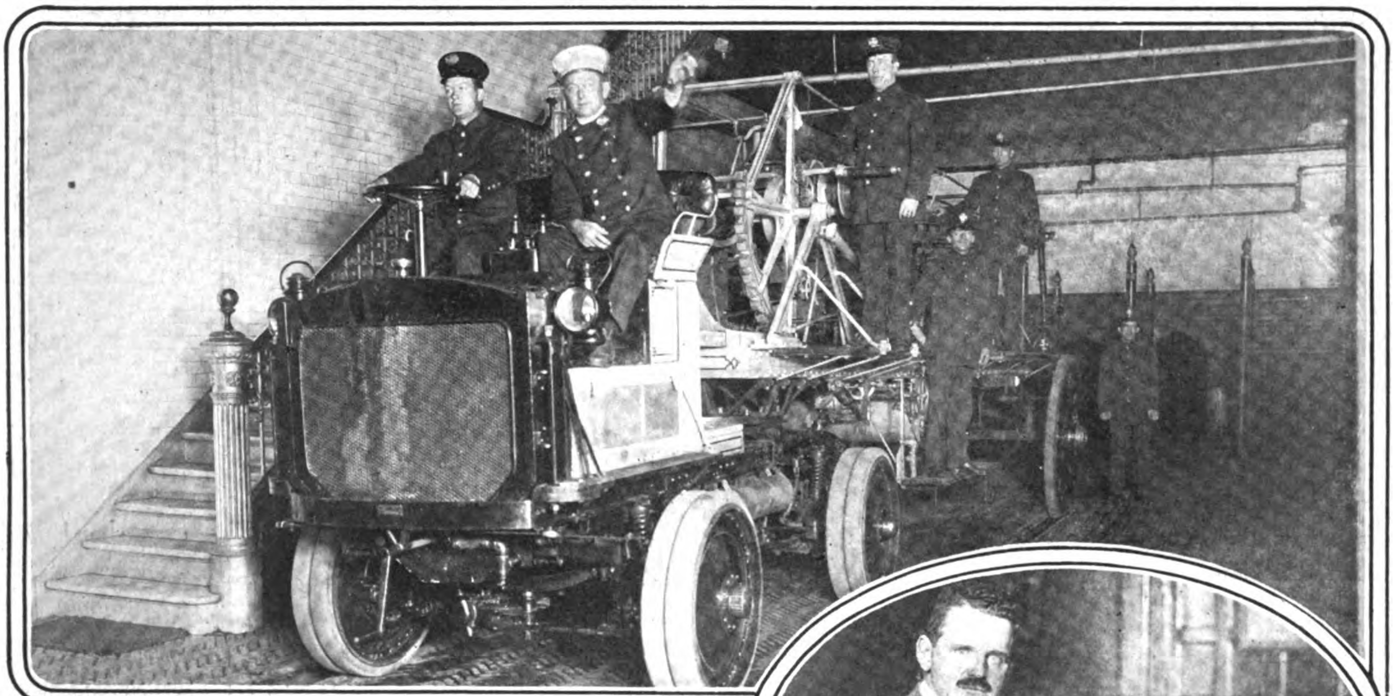
VOL. XXV NEW YORK—THURSDAY, SEPTEMBER 7, 1911—CHICAGO No. 10

THE AUTOMOBILE

Motorizing Gotham's Fire Apparatus

Past, Present and Future of Power Equipment

Commissioner Johnson of the New York Fire Department is handling a campaign which has for its objective point the installation of 150 pieces of automobile driven fire-fighting machines of all varieties. Twenty-nine pieces are now in commission throughout the five boroughs and by March 1, 1912, it is expected that there will be 100 more in service and at least fifty additional by the end of next year.



When the alarm bell summons the eleven-ton automobile watertower to duty on the firing line

Fire Commissioner Johnson of the New York Department

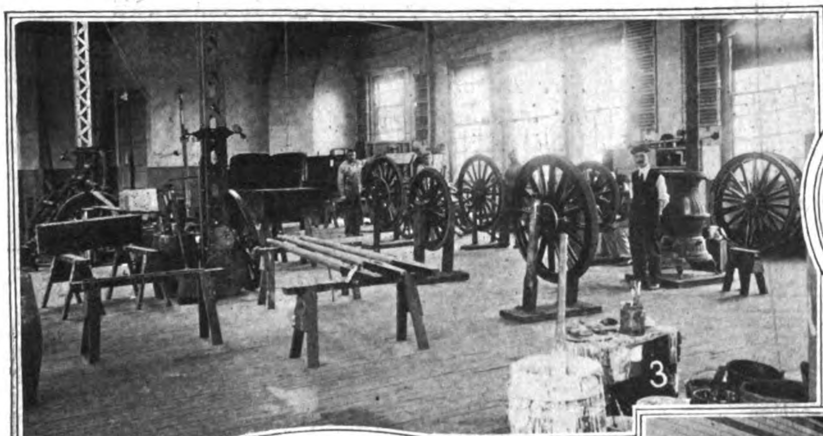
MOTORIZATION of the New York Fire Department is probably the most important step that will be taken in the immediate future as far as the progress of the automobile as a factor of utility work is concerned. The undertaking is gigantic and marks the commencement of a new era in the use of the automobile in municipal work. Not that there is not already much use being made of the automobile in fighting fires, because a start in that direction has been made and power-driven fire-fighting apparatus has been installed widely and has proved efficacious; but the future holds an immense significance along that line and progress indicated by the recent action of Fire Commissioner Johnson in preparing for the installation of 150 pieces of apparatus depending upon gasoline power for their propelling force shows that the pioneer work has borne fruit and the universal vogue of the fire automobile is now at hand.

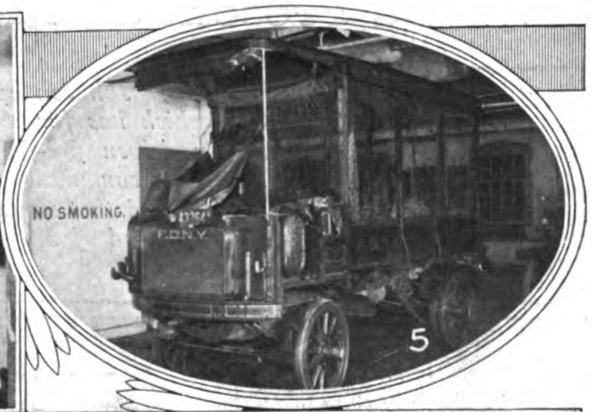
When 1913 opens the Fire Department of New York City will have by far the most complete equipment of automobile fire-fighting machines in the world. The city has tested and tried various makes of machines and to-day has twenty-nine cars in the department's service. Of these, nineteen are touring cars and runabouts used in transporting the commanding officers to their stations of duty at fires and elsewhere. The remainder are in fire-fighting service and include one Nott tractor of 110 horsepower attached to a steam engine, three Webb high-pressure hose wagons equipped with 66-horsepower motors, one Knox high-pressure hose wagon of 50 horsepower, one Couple-Gear water-tower, the motor of which is operated by electric current developed by a 40-horsepower, four-cylinder gasoline engine, two Victor trucks used as supply wagons and equipped with special stake bodies and two Knox trucks in the same branch of service. All four of the latter wagons are of 1 1-2 tons capacity.

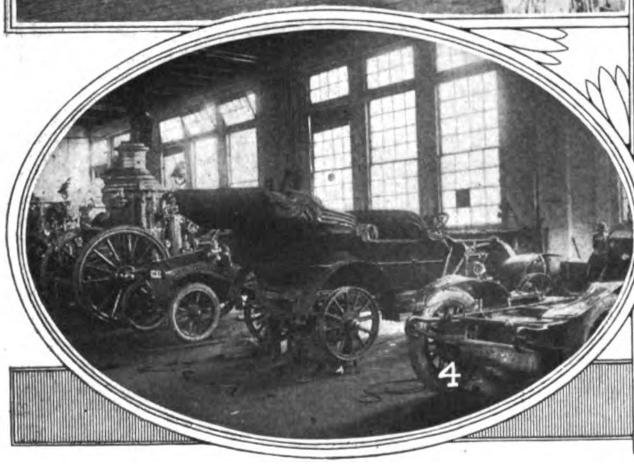
shod with tires 48 by 6 inches. The motor is a marvel of size, the four cylinders measuring 5 3-4 by 8 inches and developing 110 horsepower on the brake test. This engine has been in the repair shop for twelve days since it was put in service, the result of an accident that caused a leak in the radiator. Otherwise it has given not an atom of trouble to its crew. David J. Oliver, who drives the immense automobile, had a large share in its assembly, going on to the factory to familiarize himself with the mechanical details of the motor. The district in which the Nott engine is stationed has more than the average amount of work and on a basis of 500 miles since the engine was put into commission the yearly mileage would be in the neighborhood of 1,000.

In buying motor apparatus the department is not providing for one or two years of service, but is working for equipment that will last for many years under the excellent care that is given all fire apparatus and the limited mileage required of it.

The requirements of the department are high and hard to comply with, but an immense effort is apparent upon the part of manufacturers to gain a definite idea of the requirements with the intention of submitting bids in the near future.







3—Painting section of the big repair department for motor apparatus

4—Automobiles of the department as well as fire apparatus need repairs

5—Knox 1½-ton truck used as a supply wagon, displacing six horses

6—Webb high-pressure hose wagon stationed in "58's" house

During the rain last week a representative of The Automobile with a staff photographer made the rounds of the fire houses to obtain data and illustrations for this article, using a 32-horsepower Moon car of 1912 model, which was furnished by the courtesy of the New York branch of the Moon Motor Car Company.

The situation at present indicates much satisfaction with the apparatus operated by mechanical power and much enthusiasm on the part of the men of the department who are in contact with the machines.

At Engine Company 58, on One Hundred and Fifteenth street, near Lenox avenue, is stationed the solitary steamer owned by the department. This engine is attached to the Nott tractor, and since last March, when it was installed, it has traveled nearly 500 miles in fire service. The complete apparatus weights about nine tons. The rear wheels are fitted with the biggest solid tires ever made, they being 60 by 6 inches, while the front wheels are

Another piece of apparatus that is stationed at Engine House 58 is a Webb high-pressure horse wagon, manufactured by the Webb Motor Fire Apparatus Company. This wagon is driven by a four-cylinder, four-cycle motor, 5 1-4 by 6 inches, and rated at 66 horsepower. The motor is of the Herschell and Stillman type. The body is fitted with riding accommodations for ten men, including the driver, and carries 2,100 feet of specially strong three-inch hose. In the high-pressure district of New York no pumping engine is required to throw water high into the highest of the skyscrapers. It is said that the pressure is sufficient to raise water over 200 feet without the aid of pumps. In a cradle back of the driver rests a giant nozzle which has four connections to which leaders from the high-pressure mains may be attached.

The car is comparatively light and has high speed, and so far has shown some creditable work in service.

There is another Webb wagon at Engine House 72, on Twelfth street, near University place, and still another is in the supply department ready to be assigned a regular station on the fighting line. At 72's house there is also a Knox high-pressure hose wagon similar in body design to the Webb, but with a 50-horsepower motor.

The biggest piece of fire-fighting machinery in the equipment of the department is the watertower No. 1, stationed at 31's engine house on Lafayette street.

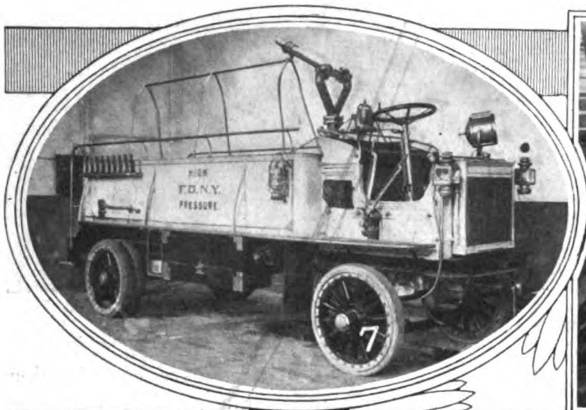
This machine is driven by a Couple-Gear motor and all told weighs 11 tons. The electric power is generated by a gasoline motor and each wheel is driven by its own power device.

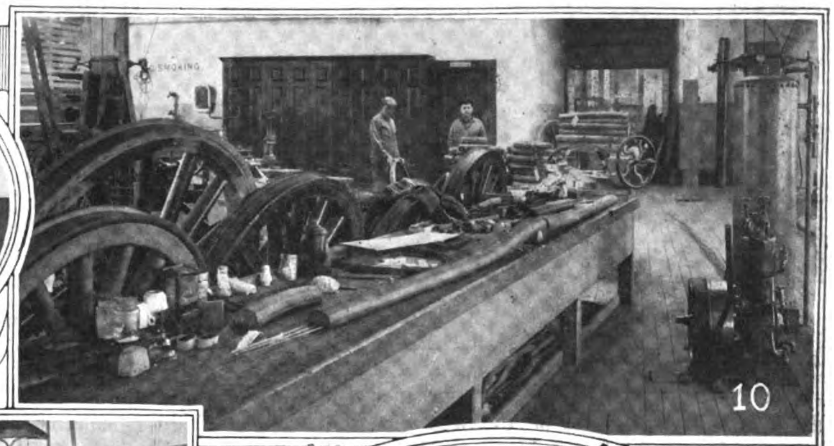
The body carries a watertower arranged to be raised and lowered on a quadrant base. The vehicle is said to be capable of an average speed of 15 miles an hour.

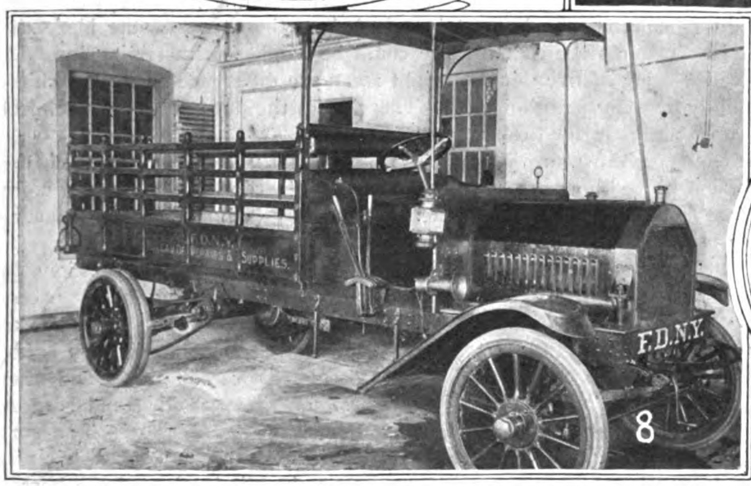
contains a school room which is being used for the instruction of chauffeurs and mechanics to drive and care for the motor-driven apparatus.

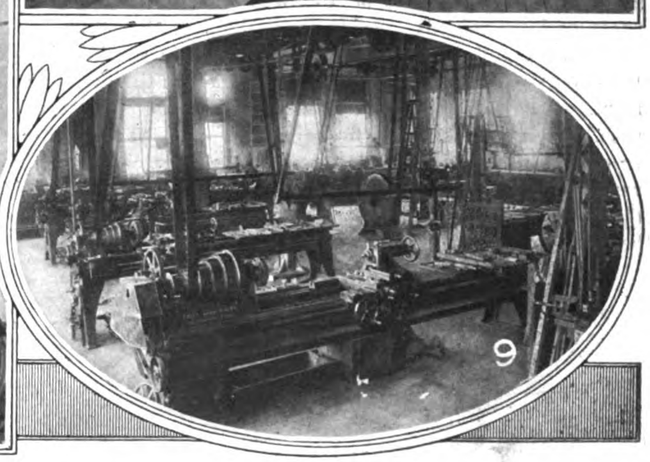
Last Thursday Professor Butler was completing the instruction of a class of firemen at the time of the visit of the representative of THE AUTOMOBILE. This class has finished its work in ignition, lubrication and other studies that may be pursued indoors and during this week will take up the driving instruction and actual repair work.

So much for the present equipment of the department. The indications for the future are for a condition that seems almost revolutionary. The department has three-quarters of a million dollars to spend for motor fire engines of various styles, sizes and duties and the specifications for the first batch of apparatus are being prepared by the technical board, which consists of Deputy Fire Commissioner P. P. Farley, chairman; Chief Kenlon, Battalion Chief J. P. Howe and Captain Demarest. This









7—Webb wagon of 66-horsepower awaiting assignment in the line of battle
8—Victor truck of 1½ tons and 30 horsepower used as a supply wagon

10—The machine tools of the department are sufficient for much work
9—Where the tires of the fire department are adjusted and inspected

Some idea of the advancement in fire fighting that is shown by the operation of these immense wagons may be realized when one remembers that the limit of size for horse-drawn engines and equipment was marked at three tons. The engine at 58 weighs nine tons and the watertower weighs eleven tons, with all that those figures mean in the way of added power, speed and efficiency.

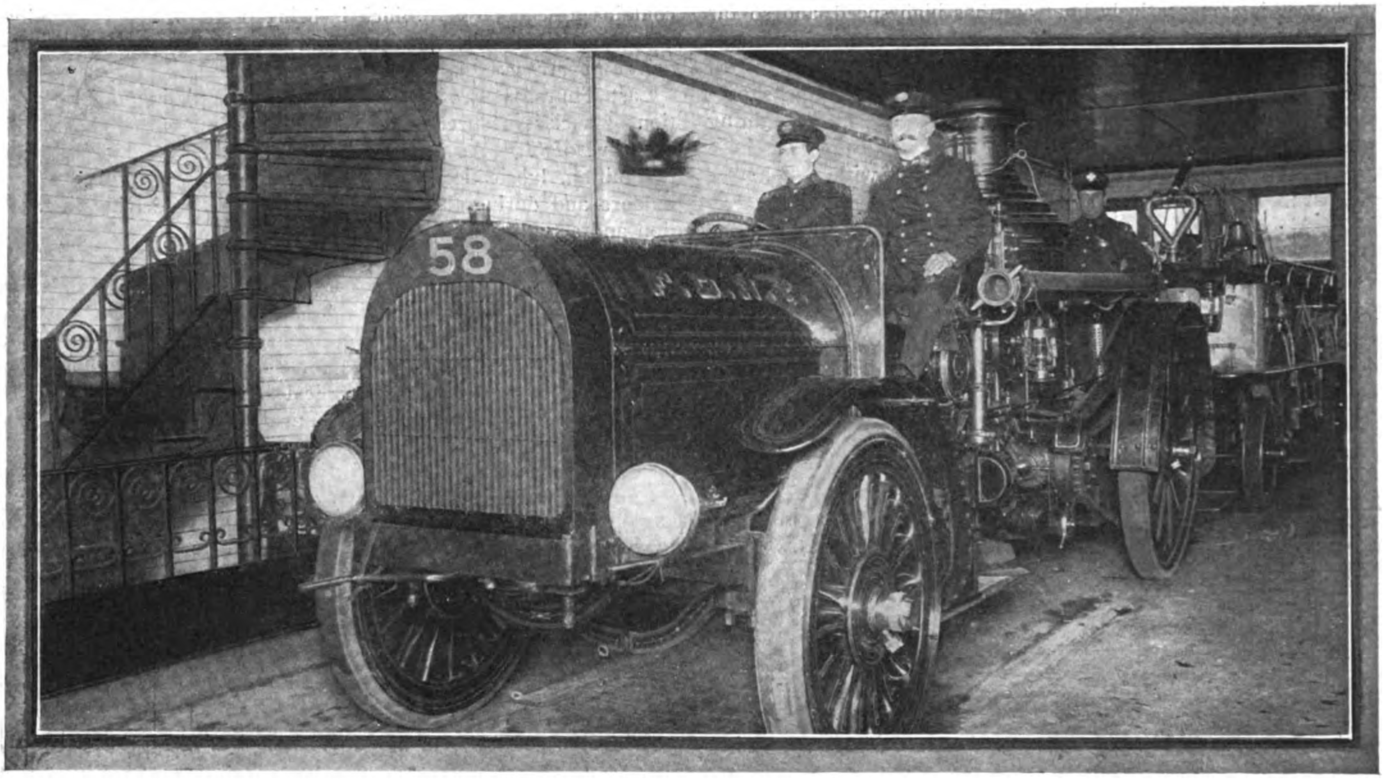
The other four wagons in present use are the 1 1-2-ton trucks assigned to the supply department under general charge of Captain Charles S. Demarest, chief of the bureau of repairs.

Captain Demarest's headquarters are at the foot of West Fifty-sixth street, where the fire department has a very complete repair and service department.

There is a special room devoted to each branch of repair, including a room for chassis assembling, forge room, foundry, storage and garage, machine tools, tires, body work, painting and varnishing and testing. Besides these branches, the department

lot of equipment will probably include about ten pieces and the chances are that they will be installed before the last of the year. During the interim specifications for other lots will be framed and delivery will be available at short intervals during the Winter. It is expected that about 100 pieces will be ready for service by March 1, 1912. By the first of 1913 it is expected that the department will have in service at least 150 pieces of motor machinery.

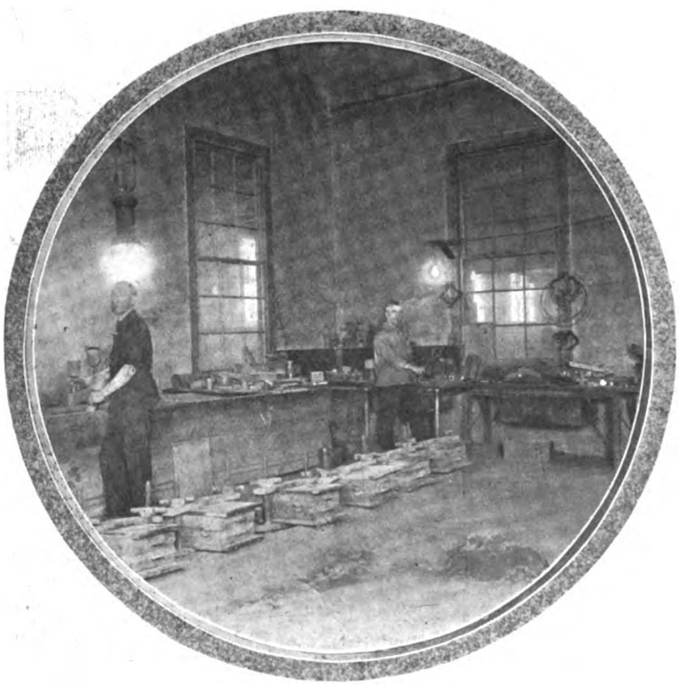
Among the companies that are taking a keen interest in the proceedings of the technical board and which are in constant touch with its activities are the following: Peerless, Garford, Gramm, Nott, Knox, Webb, Watrous, Ford, Lozier, Packard, White Combination Hook and Ladder and the Couple-Gear. All of these companies and many others will be represented at Milwaukee from September 19 to 28 when the annual convention of fire chiefs will be in session. This year the exhibition of power-driven wagons and pumps and all other types of fire-



110-horsepower Nott tractor ready to pull its pumping engine to the fire

fighting apparatus will be vastly more complete than ever before.

The New York department has practically decided upon the general lines that should be followed with respect to the high-pressure hose wagons. Aside from the fact that they must be very speedy and comparatively light, the body specifications call for two 35-gallon chemical tanks in addition to the present equipment. Thus the wagons of this type could serve a double purpose. The most disastrous fires that ever destroyed a city started from a small blaze or at least could have been controlled in the vast majority of instances by a swift dose of chemical fluid at their inception. Of course in the case of a fire starting from a fierce explosion the matter would be different, but the number of such conflagrations is small and of secondary consideration.



The Foundry, a special feature of the Fire Department service section

If the instant an alarm is struck an automobile wagon of supreme speed could be whirled to the scene of the blaze the chances are that the fire could be handled with trifling loss. A delay of five minutes might mean the difference between a chimney fire and a disaster. Therein lies the purpose of the chemical tanks in the hose wagons.

Seven more Webb wagons, identical in general lines with the three now in service, have been ordered and three more Couple-Gear trucks like the one at 31's house have been contracted for. These will be used for aerial ladders, etc.

Commissioner Johnson's plans for the wholesale additions to the present motor-propelled fire-fighting apparatus do not necessarily include standardizing any of the automobile apparatus at present in the department. The matter of standardization is being taken up by the board named by the commissioner and tests will be held to determine the best general types for standards. A new kind of apparatus is in contemplation which will be a sort of scout automobile chemical engine for the outlying districts.

One effect that will be noted in the elimination of the horse-drawn vehicles will be the lengthening of the aerial ladders and the increase in size and efficiency of the trucks used for that service.

Some of the best-informed men in the department favor automobile tractors upon which the fifth wheel of the present steam pumping engine can be placed. This would make it possible to disconnect the pump from the tractor in case of accident and substitute horses for the mechanical power. No gasoline pumping engines have answered the requirements of the department so far in the matter of volume of water thrown, but much effort is being made to perfect such a device.

Twenty-one new fire houses have been ordered by Commissioner Johnson and these will be equipped with motor apparatus. In addition to these automobile apparatus will be installed in a number of existing fire houses, thus doing away with horse equipment gradually.

Of the first 100 pieces to be purchased by the department it is likely that there will be twenty pumping engines or tractors drawing steam pumping engines, all of which, of course, will be motor-hose wagons, scout chemicals and a few cars for the transportation of administrative heads.

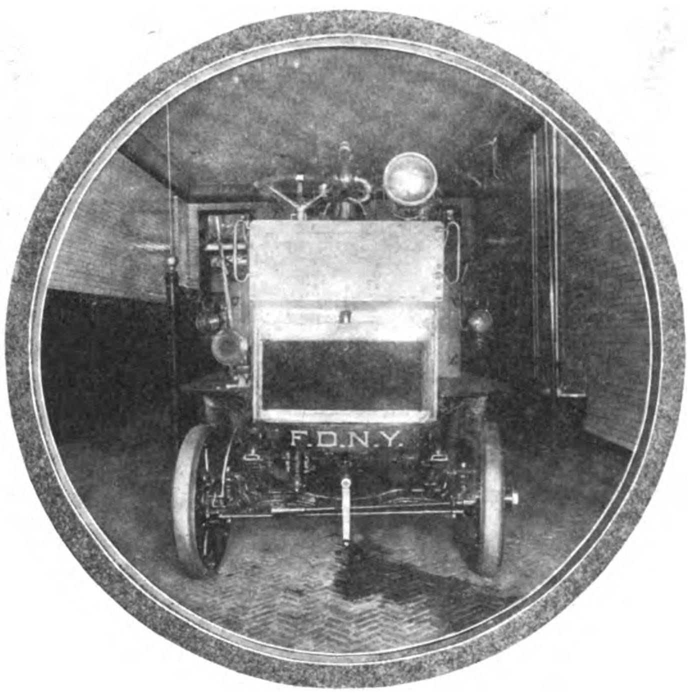
The high-pressure zone is being extended and eventually will cover all the congested districts, thus widening the field of usefulness for the hose wagon equipped with a giant nozzle and capable of taking the streams from four or more plugs.

The main advantages to be found in automobile apparatus consist in their higher speed, which allows a wider radius of action, higher efficiency because of the increased power and speed and lowest cost. The records of the department show that the average up-keep and maintenance of a three-horse team and apparatus is about $1,080 annually. This includes shoeing and feeding the horses and overhauling and repairing the apparatus.

A high-pressure hose wagon of corresponding type to the above would cost less than $100 for gasoline, oil, grease and mechanical attention and repairs, including tires. Thus the taxpayers would save $1,000 a year on the operation of each wagon that displaces three horses. In addition they gain augmented protection because of the speed of the wagons in getting to the scene of hostilities and the increased efficiency of the fire-fighting equipment itself.

Of course there would not be as much as $1,000 difference between the cost of operating a tractor drawing a steam engine and a horse-drawn steamer, because the water in the boiler has to be kept hot all the time, no matter what the motive power of the apparatus. But even on that basis there is a sharp economy shown by the elimination of the horses that formerly pulled the steam pumps. It is likely that the saving would amount to $700. It is easily figured that the department will save at least $120,000 a year when the 150 pieces of motor-driven apparatus have been installed.

The men who are connected with the companies to which automobile engines and wagons have been assigned are enthusiastically in favor of them. The absence of horses from such fire houses is a welcome relief to the noses of the men and the lack of flies is certainly appreciated by the men who are obliged to sleep in daytime. No matter how much a man may love the horse he hates to clean him, and no matter how educated the sense of smell may be nobody to date has confessed to liking the strong ammoniacal odor inseparable from horses.



Knox hose wagon, a 50-horsepower truck assigned to Engine House 72

The streets of New York, particularly in the congested, high-pressure districts, are in fearful condition for fast operation and the commissioner has entered protest with the borough officials. The strain on automobile mechanism traversing some of the rough streets is almost impossible to sustain and is most unfair in the way of a test of efficiency. So far the various engines and other apparatus have stood up staunchly, but unless the streets are repaired or paved the usefulness of such apparatus will be reduced in a pitiful manner and much of the well-intended improvements and innovations of the commissioner will be nullified by the *laissez-faire* attitude of the department in charge of the work of keeping the city streets in good condition.

Blitzen Benz Sets

During the two-day automobile meeting Burman in the giant Benz car established a a circular dirt track. There was a great on Saturday. The fields in all the races except Saturday were wide, while on Monday they

NEW MARKS were set for the one and two-mile distances on circular dirt tracks at the two-day automobile race meeting that came to a close on Labor Day at Brighton Beach. The Blitzen Benz, driven by Burman on Saturday, reduced the two-mile record to 1:37.89, knocking off about three seconds from the best previous time for the distance. On Labor Day the same car and driver clipped 1-10 of a second from the mile distance, making the circuit in 48.62 seconds.

The track was in better shape than ever before, especially on the final day, and with good weather two big crowds turned out to enjoy the sport. There were probably 15,000 paid admissions during both days. Only one accident happened and that was not serious. This incident came off in the final race on Labor Day, when Spencer Wishart, in his big Mercedes, attempted to catch the flying Mercer in the handicap race. The car blew a right rear tire at the club house turn and plunged through the fence overturning with the young millionaire. It was in the last lap of the race, which probably accounts for the lack of fatalities, for to the amazement of the big crowd, no sooner had the car capsized in the ditch than an ambulance dashed out on the track among the rushing contestants and galloped up to the prostrate Mercedes. Wishart certainly would have been no worse than second but for the accident.

Of the racing there is little to be said. On the first day the finishes were all tame and on the second they were all close. They were so tame on the first day that the spectators lost interest to a great extent save in the first heat for the Remy Bras-

Fall at Brighton

New Marks Sprinting

at Brighton Beach, which ended Labor Day, new level for the one and two-mile circuits of crowd present on Monday and a good one the handicaps were small and the finishes on were of the eyelash variety.

sard and trophy. In this event three entries from the Moross string constituted the field and the most carping critic could no: wish for a prettier race or a more stirring finish. In fact all three cars led at one stage or another and a blanket could have covered them at the finish. It was highly artistic, particularly Disbrow's driving of the Mercedes representative of the string. The final heat was also a spectacular triumph with the result never in the least doubt but the winning margin was slight. The big crowd was somewhat astonished when it was announced tha the Moross Mercedes was to be driven by Oldfield, but their fears were quieted when it was learned that the driver was not the redoubtable Barney, now under the official ban.

Close finishes were the order of the day in the final session. In fact, it seemed as if the "order" was followed a trifle too literally. In several of the races the winner lay off the pace and just nosed out the second horse in furious drives that aroused much enthusiasm. The first event was taken by an E-M-F, or rather the E-M-F which just galloped all the way and won going away. The Mercer took the second without much of a struggle and National 20 annexed the third class race. The same car also won the big class event in comfortable style. The first heat of the Brassard contest was won by the Benz in a nose finish with its stable mates, the Jenatzy Mercedes and the 200-horsepower Hotchkiss.

The 50-mile feature brought out a field of four cars including an Opel, Mercer, National and Jackson. The Opel set a fast pace for five miles when it was headed for a moment by the

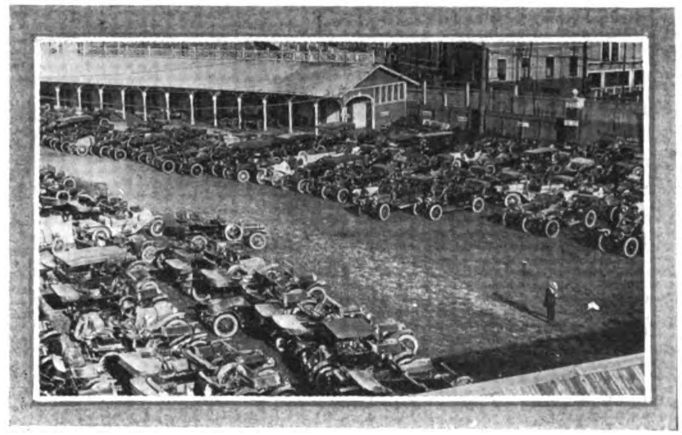
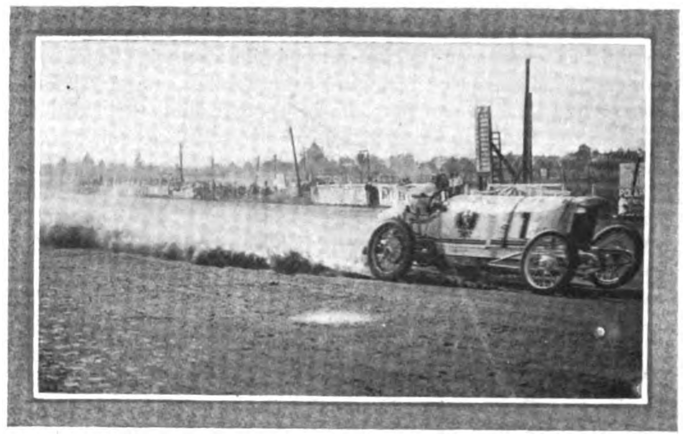
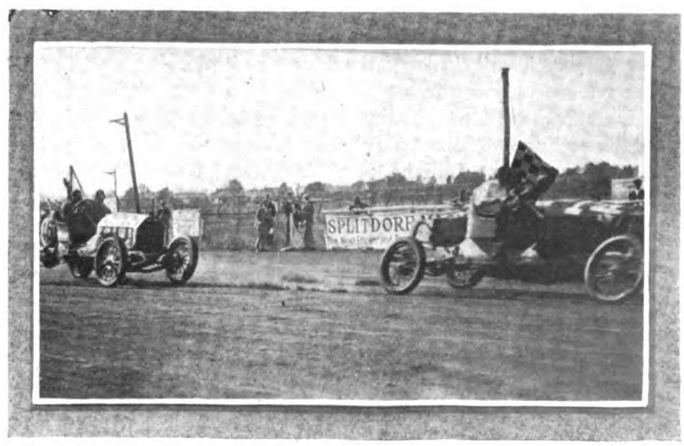
Hotchkiss No. 8 doing the clubhouse turn in Remy Brassard race



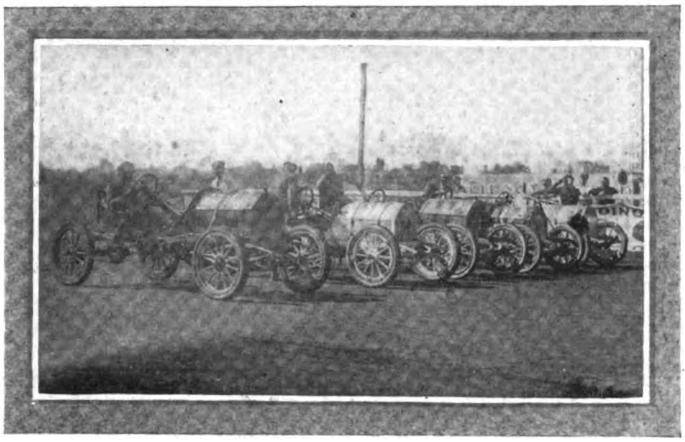
Some five hundred cars parked at Brighton Beach on Saturday



Burman in Benz breaking one-mile track record in 48.62 seconds



Opel (Burman) and Benz (Oldfield) in a close finish



Jackson, Paige-Detroit, Penn "30," Lancia and E-M-F (wniner) lined up for small car race

Mercer and then reassumed the lead clear to the wire. The National suffered tire trouble early and often and was afflicted with a sooty spark plug in the middle distance, losing eleven laps during the tire changes. The Jackson pursued a troubled course for half the distance and retired from what was announced to be carbureter troubles. The Opel ran steadily and quietly from start to finish, closely accompanied by the Mercer, until the forty-seventh mile, when a dangerous blow-out on the clubhouse turn caused the loss of over a lap. Hughes handled his car in masterly style and after limping around to the paddock made a wonderfully quick tire change and was out on the track again in pursuit of the curious looking German car. The Opel won eased up in 50:07.13, slightly less than 60 miles an hour.

The last race of the first day was the prettiest on the card. It was a free-for-all handicap and a Benz car from scratch proved the winner, getting up in time to defeat the Mercer and E-M-F in a wild drive.

The second day's card furnished a series of the most remarkable finishes ever seen in any automobile races. The E-M-F lay second and third for four and a half miles, taking the dust of the Paige-Detroit and part of the time trailing the Penn 30. But when the final run came along Tower moved up quickly and swung into the stretch on even terms with the pacemaker. From there to the wire it was a hair-raising struggle with the honors going to E-M-F.

In the second race it seemed impossible to make a contest with only the Mercer and Schacht entered, but Hughes in the Mercer proved the fallacy of such a supposition. The Schacht led for part of the distance or until the Scotch driver was ready to get into action and then there was nothing much to it but the Mercer.

The Opel showed its quality in the third class event by winning from a Benz and a National. Burman at the wheel of the winner was first at the wire rather easily by a very tight margin, with Oldfield in the Benz just far enough away to get second money. As has been recounted, the final heat of the Remy Brassard was another magnificent triumph of art and clever driving by all three of the Moross pilots.

The ten-mile event for big cars brought a field of four to the line, including the Opel, National, Mercer and the big Mercedes racer owned and driven by Spencer Wishart in the recent 500-mile sweepstakes at Indianapolis. The Opel made the pace all the way, but the Mercedes kept shooting at the leader on every turn only succumbing at the very end. The Mercer was a close third the National going out with a puncture on the first turn.

The fifty-mile race went to the Mercer, after the Mercedes had suffered its second blowout. The pursuit of the low-hung yellow automobile driven with supreme skill by Hughes, by the big-hooded gray racing car was extremely interesting. Hughes never took a chance and when he found that his rival had eliminated himself from first place, barring a broken axle or something of the sort, he finished the distance easing up and allowing the Mercedes to regain a lap.

The last race of the day and meet looked like a tragedy for a minute during the last lap of the free-for-all handicap. There was a big field on the track and the Mercer had gradually worked through the small fry and was out in front passing the stand on the last lap. Up the stretch was the E-M-F that had shot its bolt and directly behind the Michigan car came the National and the Wishart Mercedes. The National was going well for the first time during the day and Wishart was pushing the German car to the limit. The National was on the rail and when Wishart opened up at the wire the Mercedes shot ahead and took a long slant for the first turn, intending to displace the National and close the gap on the leader. Wishart made a quick rush for the turn, but was so close to the National after taking the rail position that the National was obliged to hold hard and shut off.

Suddenly the stands were electrified by the sound of a tire explosion and out of the cloud of dust the big gray car was seen to make a dive diagonally across the track. Clear to the pole the car shot with the driver doing manful work in an endeavor to hold it on the track. Just for a second it seemed as if he would succeed and then a cloud of fence rails and splittered posts told the tale of going through the fence.

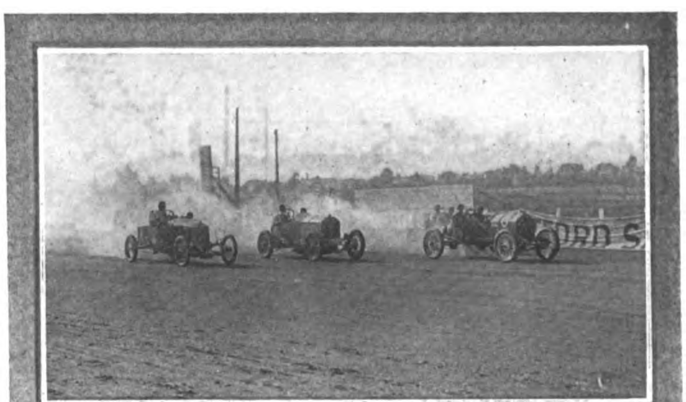
The car tottered on the side of the ditch and then turned over, Wishart leaping out in safety. The extraordinary proceeding anent the visit of the ambulance among a dozen racing automobiles has been told. Just why the driver did not take the regular road is one of those mysteries for which there is no explanation. At any rate he did not do so, but nobody was hurt. The meeting was a glittering success from the financial and artistic viewpoints and the public got a great big measure of interesting spectacles.

Preparing for Chicago's Six-Day Run

CHICAGO, Sept. 3—The pathfinding trip for the Chicago Motor Club's reliability run was completed to-day when the Halladay scout car carrying John P. Dods of the Official *Automobile Blue Book* and his staff drove in from Grand Rapids, Mich.

Several changes have been made in the original route laid out, particularly on the second day. Instead of going from Indianapolis through Terre Haute and Vincennes to French Lick, stopping half of Sunday at the last-named place, then driving to Louisville in the afternoon, it has been decided to go south to Seymour via Franklin and Columbus, then west through Brownstown to Bedford, Salem, Pekin, Borden, New Albany to Louisville, where Sunday will be spent. The third day's run will be from Louisville to Cincinnati, the fourth day to Columbus, the fifth day to Detroit, the sixth day to Grand Rapids and the seventh home, a distance of approximately 1,400 miles.

The run will be a stock-car proposition and will be a grade 1 event with technical penalties and technical examinations to determine the winners. There will be two divisions, one for touring cars and the other for runabouts, while in addition there will be a team trophy and a fuel economy prize.



National (Sheets), Mercedes (Wishart) and Opel (Burman) in the fifty-mile race on Labor Day

A Plethora of Valveless Ideas

Differing Materially From Conventional Practice

In the series of valveless motors illustrated in this motor one thing that will strike the reader is that they differ in many ways from what has already been done along this line. Who knows but what among the apparently impossible propositions that have been evolved in the last few years there resides the basic principle of an entirely practical, successful motor.

THE man who said "There is nothing new under the sun" might have modified his ideas if he had lived in the twentieth century. There is no doubt that the proposition of evolving something new in the endeavor to create a motor that will do away with the poppet valve has given a good deal of food for thought to the inventively inclined.

Martin Uses a Rotary Valve Consisting of a Split Ring

The objects of the invention shown in Fig. CC are to balance the valve carrier and construct a valve in such a manner as to avoid pressure thereon, and to provide a silent-working mechanism of simple construction for controlling the gases to and from the cylinders. (A) in Fig. CC represents a transverse section of a cylinder of the motor. The working cylinder A has two ports, B and B1, which first act as inlet ports and then as exhaust ports. C represents the valve casing, and the rotating valve shaft E is carried in the bearing D. F and G represent the inlet and exhaust passageways in the valve casing. H and H1 act as valve carriers. The split rings I are formed in the shape of tubes, and each has a gap at I1 between its edges, being open at both ends. The valve finds a seating at C1, and C2 in one of the passageways in the valve casing which place the valve in communication with the cylinders. The valve carrier H is formed with disc-shaped ends H2, which fit against the cylindrical interior of the valve casing, and are held in position by the valve covers D1. Each pair of these discs H2 is connected by a central portion or rod of reduced sectional area, which at its center is provided with a disc H forming the valve carrier. Around recesses H3 in the exterior of the valve carrier H are pinned the split rings or valves I, which by being placed in the recess H3 are properly balanced. This construction prevents pressure from getting inside the valve ring I and expanding against the valve seating. The valve carriers H have grooves cut in them. The intake and exhaust ports F and G are placed in the head of the cylinder,

Oscillating Valve with Shuttle Cam of French Design

The principle involved in the design of the motor shown in Fig. CD is applicable to cylinders with the valves in double file, as well as in the single file form illustrated. The valve V acts as a distributor valve, controlling both inlet and exhaust ports by its reciprocating motion, which is effected by a shuttle cam C through the medium of a roller R carried by the oscillating foot F of the valve spindle. The motion may also be imparted by an adjustable bell crank with a hardened toe-piece in contact with and rocked by a cam of conventional form. During the reciprocating movement, excepting when subjected to the pressure of compression and explosion, the valve is relieved of contact by a coiled spring S interposed in the vertical shaft S1, the latter being split for that purpose. The shape of the valve V is shown in the plan view of a cylinder B in Fig. CD. The working cylinder A has a port P, and as the valve V reciprocates, the inlet and exhaust passageways are uncovered, placing the cylinder in communication with them.

Ward Motor Has Sliding Block in the Cylinder Head

The method of controlling the gases in the motor designed by W. C. Ward is shown in Fig. CE. The cylinder wall is cast with a lug L1, which acts as a bearing to the upper end of the vertical shaft S, which is driven by suitable means from the crankshaft at half-speed thereof. The upper extremity of the shaft carries a cam-shaped disc A, with a specially grooved slot B cut therein, in which is engaged a roller C of the slide valve D. The valve proper is formed with exhaust ports E and F, and a transverse web G which has an enlarged foot to cover the cylinder port J during the time that the motor is compressing and exploding the gases. The cam A being rotated, the valve D will move to the left, which will place the port J of the cylinder into communication with the exhaust ports E and F, allowing the burned gases to find an exit through the passage K in the cylinder head, which, as will be seen, is amply provided with water-jacketing surfaces. The continued rotation of the cam A draws the valve D in the opposite direction (to the right); when the foot of the transverse web G passes over the port J, the latter will be placed in communication with the valve chest L and the induction manifold through the port N.

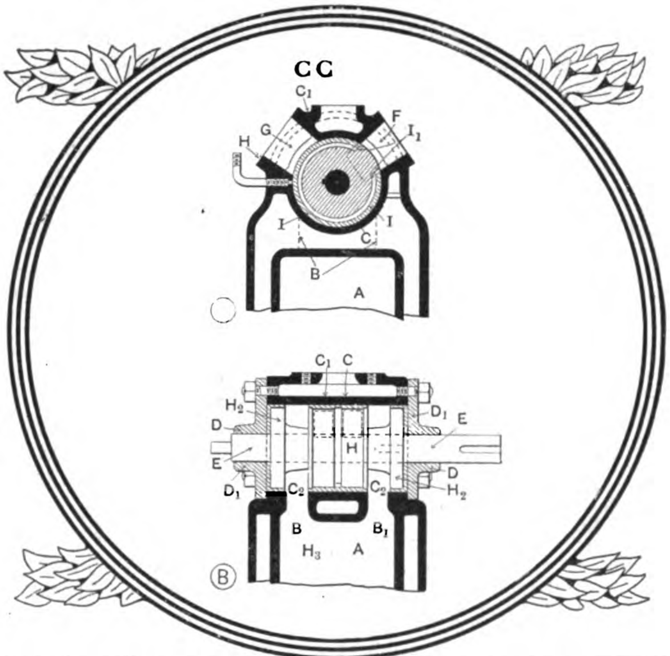
A Combination of a Rotary and Poppet Valve

The section of the head of a cylinder shown in Fig. CF is the invention of W. McLeod, Coventry, England, and shows how a poppet valve has been combined with a rotary shutter valve in controlling the gases. As will be seen in Fig. CF, it consists of a single poppet valve of unusually large size which controls the opening of the exhaust and closing of the induction, and a rotary valve which controls the operations of closing the exhaust and opening of the intake. The valve setting, which is taken from the *Autocar,* is shown in Fig. CG. The rotary valve runs at half engine speed and has but one port, which is of slightly oblong shape. At the point where the exhaust opens the port of the rotary valve coincides with the exhaust passage, so that on the poppet valve A being depressed by the cam J there is a free exit for the burned gases. The cam J holds the poppet valve open while the rotary valve continues its revoltuion until the port is closed, thereby finishing the period of exhaust. Continuing its rotation, the intake port is placed in communicaion with the cylinder through the slot in the rotary valve and as the poppet valve has been held open all this time, this closes when the piston has started to ascend on the compression stroke. During the compression and working strokes of the piston, the poppet valve is held closed by the spring S, the rotary valve, however, continuing to rotate, so that by the time the piston has descended and is within 42 degrees of the bottom of its stroke, the poppet valve again opens, placing the port P in communication with the cylinder.

The rotary valve in this motor is entirely unaffected by the pressures in the cylinders, as during compression and explosion strokes it is covered by the poppet valve A. The poppet valve remains open twice as long as is the case in the ordinary arrangement and owing to its large diameter only a small lift is necessary. The method of operating the valves can be seen by referring to Fig. CF. The shaft is caused to rotate either by means of a silent chain which is becoming the accepted form for this style of transmission, or by a vertical shaft driven by bevel gearing from the crankshaft. The shaft carries a series of cams J, and a wormwheel G. The operation of the cams is conventional and needs no explanation. The gear G meshes with the gearwheel G1 attached to the extremity of the shaft F, which at its other extremity carries a bevel gear. This meshes with another gear E attached to the rotary valve B. The spindle of the poppet valve A passes through the hollow spindle of the rotary valve in the manner shown.

Rotary Disc Valve of the Blood Motor

This type of motor, shown in Fig. CJ, was described recently in The Automobile and consists of a rotary disc valve with a port cut therein which is caused to register with the intake and exhaust passageways, being operated by means of three sets of bevel gearing. The shape of the motor casting is clearly shown in the longitudinal section of the motor, which is of the single-cylinder, four-cycle type.



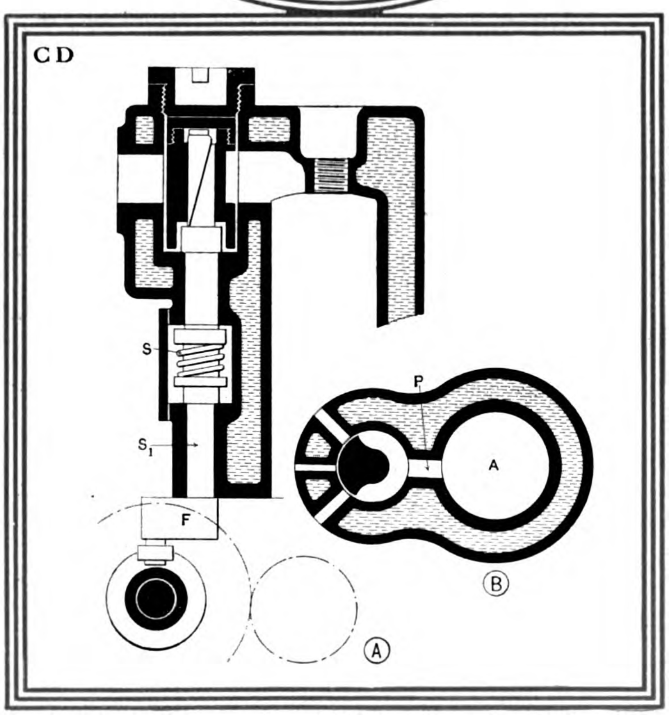


Fig. CC—Sectional views through the Martin Motor, showing the construction of the rotary valve

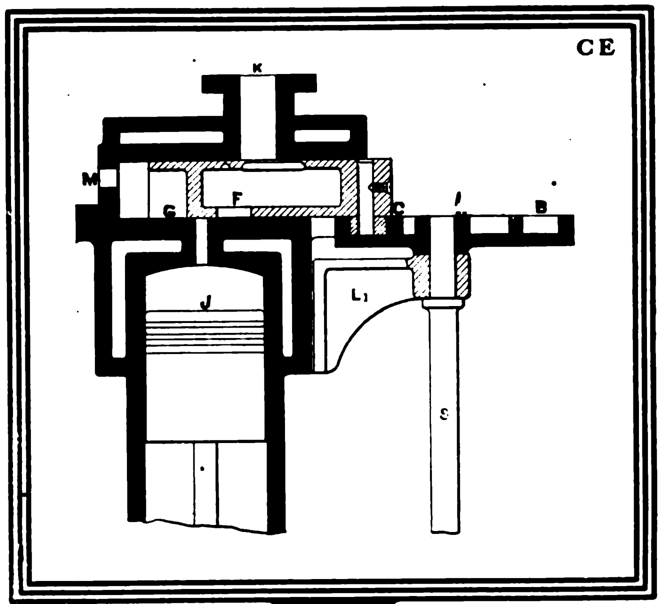
Fig. CD—Sectional transverse and plan views of a motor, with an oscillating shuttle cam valve

Hewitt Controls Tandem Cylinders by Piston Valves

This invention relates to the method of working tandem differential-cylinder, internal-combustion engine, which consists in cutting off the supply of mixture to either cylinder independently, or to both cylinders, and simultaneously opening such cylinder or cylinders to the atmosphere, so that three different powers can be obtained. The point of interest in valveless motors consists in the methods by which a tandem engine is controlled by piston valves working in cylinders open at their ends to the two engine cylinders. Fig. CI is a transverse sec-



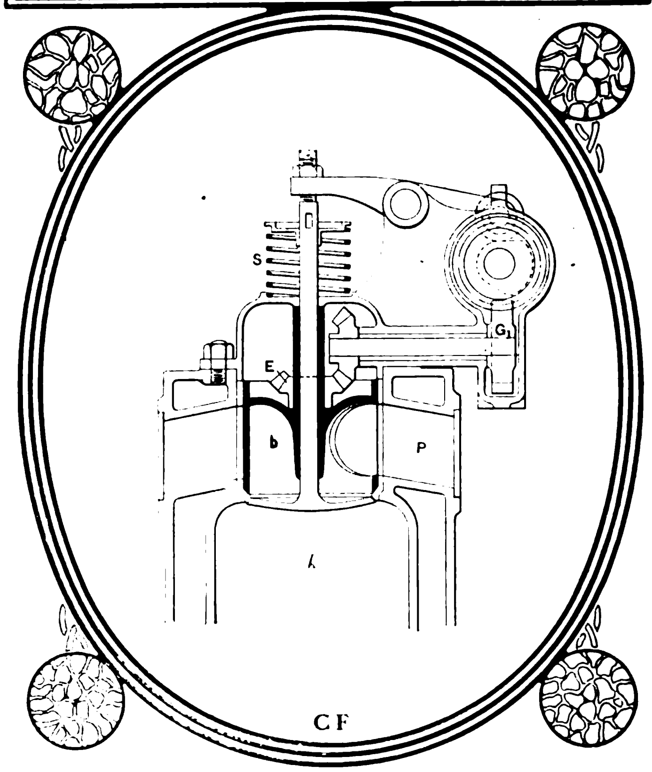


Fig. CE—Ward motor, showing the method of operating the slide valve in the cylinder head

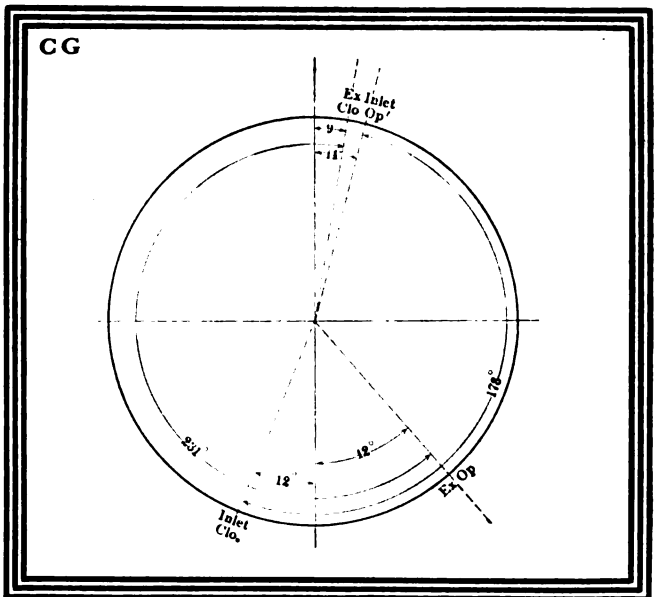
Fig. CF—Combination of poppet and a rotary valve employed in the McLeod motor tion through the induction valve of the motor; the two cylinders A and B are arranged one above the other in tandem form, the lower one being of larger diameter than the upper. The piston C is continued down and carries the lower piston B. The valves are double-ended pistons, are driven at half-speed from the crankshaft. They are set to uncover the ports alternately at either end of the piston valve, so that openings and closings to one cylinder are repeated half a revolution of the



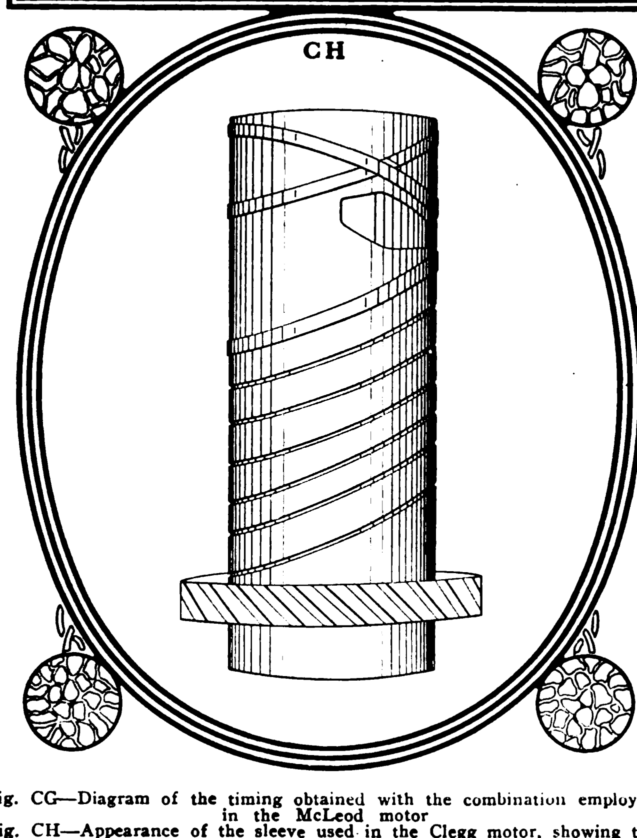


Fig. CG—Diagram of the timing obtained with the combination employed in the McLeod motor

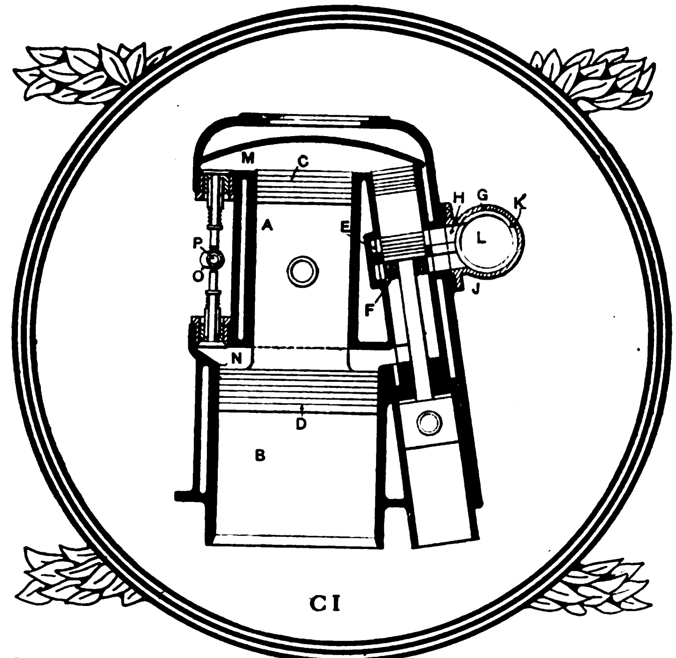
Fig. CH—Appearance of the sleeve used in the Clegg motor, showing the elliptical expansion rings

valve crank afterwards in the other cylinder. Each cylinder has induction ports E and F, which open separately into the induction pipe G, forming valve ports H and G. A sleeve K, rotating within the induction pipe G, has a port L registering with the ports H and J in the induction pipe. The two air or relief valves M and N have springs which are strong enough to resist the suction during the induction stroke, and their stems terminate to meet the cams O on the shaft P, these cams being so arranged that either or both valves can be opened, thus nullifying either or both cylinders. The sleeve K and the shaft P. are connected to a lever under the control of the driver.

Clegg Uses Elliptical Rings with Rotary Sleeve

The sleeve shown in Fig. CH is one from a motor designed by W. H. Clegg. The feature of this construction lies in the man-



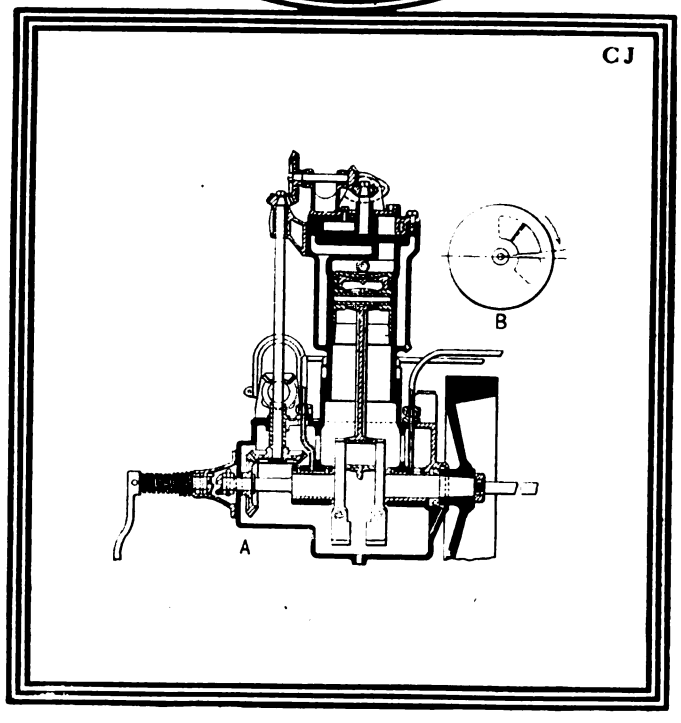


Fig. CI—Section through the intake valve of the Hewitt motor, in which tandem cylinders are employed

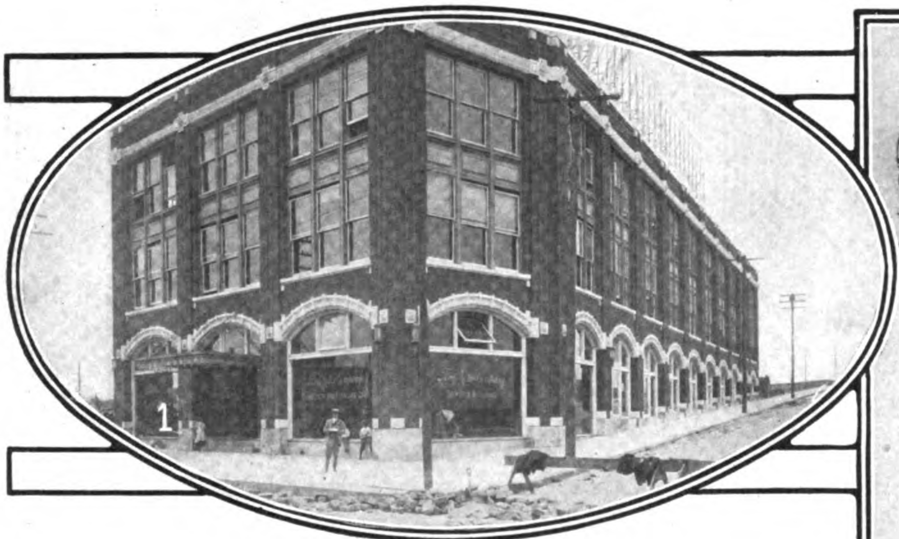
Fig. CJ—Section through the Blood rotary disc-valve motor, showing method of operating the discs

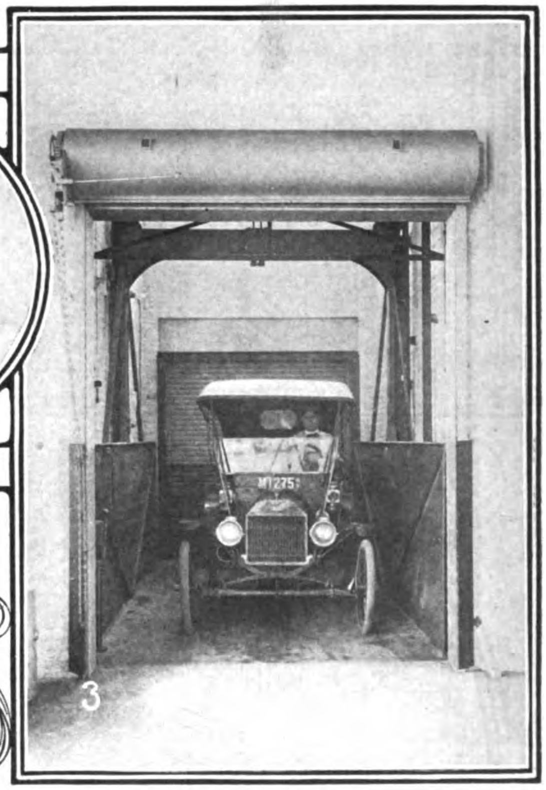
ner in which the rings are cut and fitted; these are elliptical in shape. By making a simple attachment to an ordinary lathe, there is no difficulty in cutting the grooves in the sleeve or turning the piston rings in the manner shown. The idea of the inclined ring is to prevent uneven wear, and each ring comes into contact with a far larger surface of the cylinder wall than would be the case with the ordinary type of ring. It will be noticed that the grooves in the cylinder are cut elliptically.

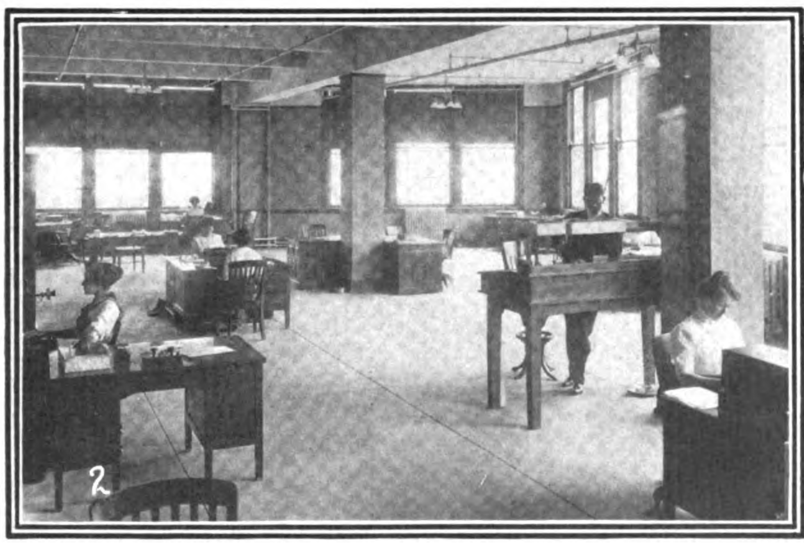
More Service for Ford Owners

Long Island Building Open for Work

Complete plant of the Ford Motor Company, dedicated to keeping the cars owned in territory contiguous and adjacent to New York in running order, has been finished and already a large force of men is employed in all departments. There is much room for expansion, and the present big building could be run up ten stories on the existing foundation if the necessities should require.







1—The new Ford service building at Honeywell street and Jackson avenue, Astoria, L. I.

2—The main offices located on the second floor are large and commodious

3—Elevator connecting the various floors and one of the inlets from the railroad landing

TEN thousand owners of Ford automobiles living in New York, New Jersey and Connecticut will be interested in learning that the magnificent new service department of that company practically has been completed and is prepared now to take up its work for them.

Good service is now regarded as one of the most important advantages to offer a prospective buyer and almost without exception the makers of automobiles have recognized the fact in some degree. The expression of this phase of marketing automobiles in New York takes various shapes and forms, the highest examples of which are shown in the new buildings of the Packard Motor Car Company, the Ford Motor Company, the White Company, Pierce-Arrow and several others.

Millions of dollars have been invested in these enterprises and only a real good start has been made so far. Judging from the past and present, the future holds out the certainty of numerous similar installations.

Service in its applied sense means keeping the car on the road. No matter how much a car may have cost it is worthless unless it will run, and the value of the "service department" is measured exactly by the amount it serves in time and expense in keeping the car running at high efficiency.

The Ford company has had a service department connected with its New York branch house for years, just as most of the selling companies in New York are equipped, and the new building simply means an attempt to furnish more and better service.

The lot, which is 250 by 265 feet, was purchased about two years ago and the building was commenced in March, 1910. The lot faces on Jackson avenue and Honeywell street, just where Astoria and Long Island City come together. Jackson avenue is the main artery of travel from the Queensboro bridge, and Honeywell street is only about half a mile from its eastern end.

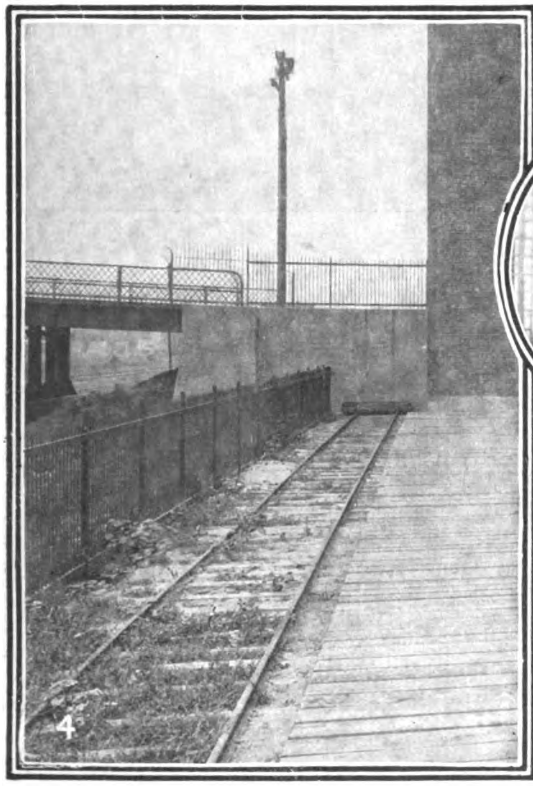
Plenty of Room for Expansion

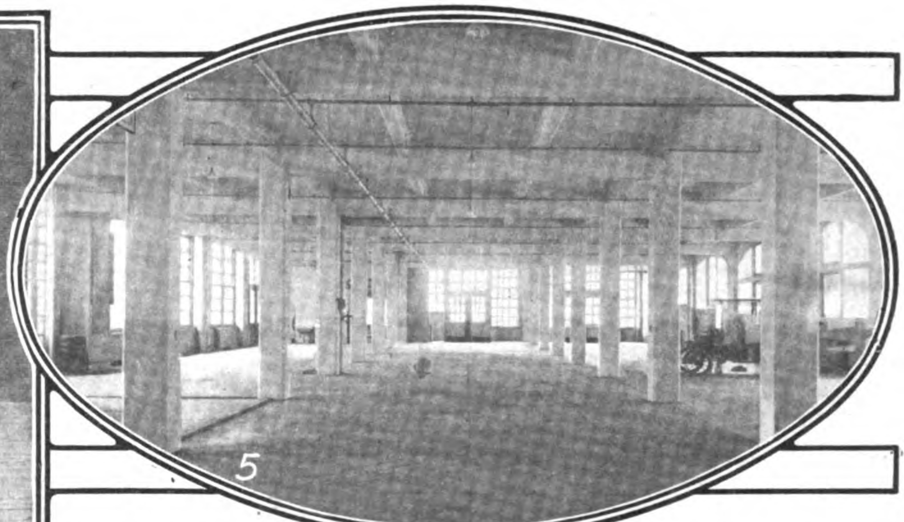
The present building occupies only a part of the lot and its construction has been accomplished with the idea of future additions. For instance, the walls are much thicker and more substantial than would be required for a building three stories high, and the roof as it stands to-day could be converted into another floor at small expense.

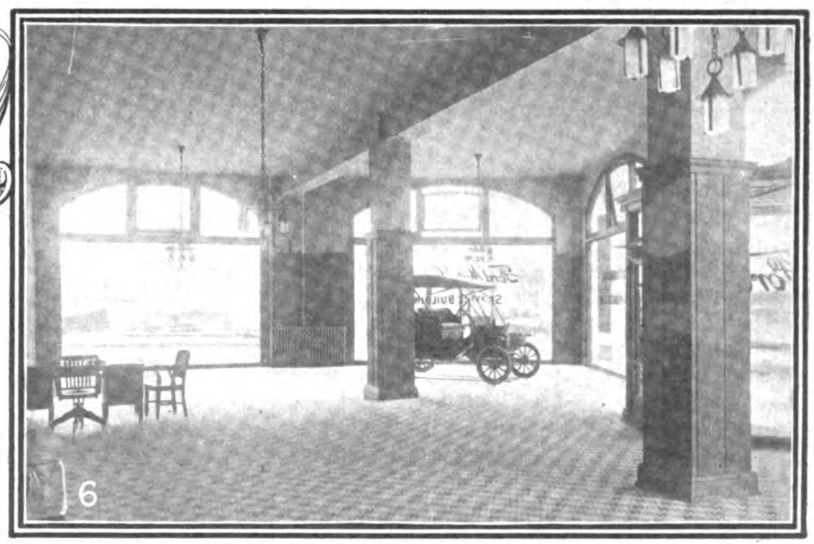
The present building measures 75 feet in width by 223 feet in this part of the plant. The floor space of each of the four floors is 15,800 square feet or a total of 63,200 square feet in the four floors.

The main floor is divided into two parts, the front being cut off from the main room by a bulkhead at the second file of pillars. The interior of this room has been fitted up with massive but severely plain furnishings and decorations. The pillars are paneled with oak and the floor is tiled with enameled material. The front and both sides are occupied with wide show windows and the room will be used as a display place. The ceiling is 15 feet 9 inches high.

Back of the bulkhead is the garage, another giant room extending to the rear line of the building, rectangular and measuring 175 by 75 feet. At the side entrance of the building is stationed the timekeeper of the plant and the man responsible for the comings and goings of men and material.







4—Long platform beside Ford plant from which seven cars can be unloaded at once

5—Showing the size of the storage room and garage on first floor of the building

6—The show room, finished substantially in tile, concrete and hardwood panels

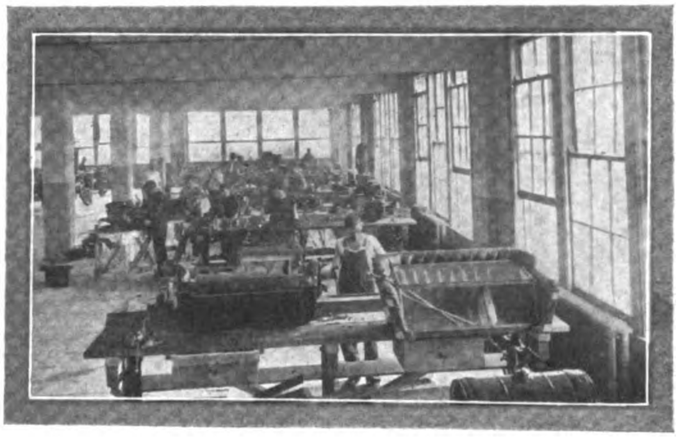
on Honeywell street and 195 feet on the inside of the lot.

Its foundations are of rock and concrete and its walls 2 feet thick. The sub-basement, floored with concrete cement, is all thrown together in one vast room which is used for storage of completed cars. The ceiling of the basement is 12 feet 9 inches high and is connected with the outside and the other floors by a giant electric elevator. At the back end of the basement is the boiler room, which is separated from the rest of the structure by fire walls and is so isolated that one cannot reach it unless by going outside the building and entering from the rear.

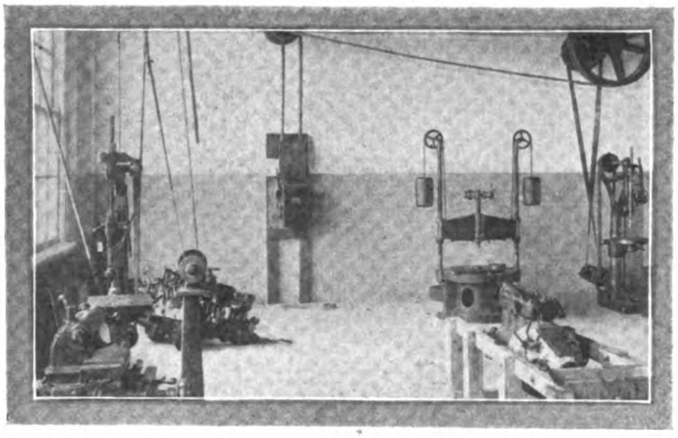
Twenty massive pillars of reinforced concrete extend in double rank through the building longitudinally and are carried from sub-basement to roof. There is storage room for 300 cars

How the Spare Parts Are Carried

Ample room is afforded for over 200 cars on what would correspond to "live storage" in the ordinary garage. Like each of the other floors, this one has connection of course with the elevator, and at the rear of the building a spur of the Pennsylvania Railroad reaches across the whole structure and along a substantial freight platform so that seven cars can be loaded or unloaded at the same time. A door at the left side of the building also affords an inlet into the main building from the platform. The same may be said for a door through the center of the rear wall.



7—Where the actual work is done; the first table is for body repairs; second and third, engine assembly, and others, transmissions, axles, etc.



8—Machine tools with which the Ford service plant is equipped

The second floor, the ceiling of which is 14 feet 6 inches high, is one of the most interesting and important factors of the plant. In front and corresponding in size to the showroom on the ground floor is the office where fifteen persons are employed with records, correspondence and accounts. Back of the cross-bulkhead is the parts storage department. At the left side of the room is a series of adjustable bins of various sizes, all opening upon small aisles. These bins are numbered to correspond with the catalogue parts of the Ford automobile and there is one for each screw and washer, spring clip and block of cylinders, side member and ignition system as well as every other part contained in the automobile.

The card contains a statement of how many of the pieces have been placed in the bin and when any are withdrawn in filling orders, the fact is noted on the card before the clerk moves away from the bin.

There is a plain warning in each bin as to the minimum number of parts of the particular kind that it should always contain and when the stock has been reduced to that minimum level orders for replenishment are given. When a part is withdrawn, the clerk not only notes that fact, but he subtracts the number of parts he is taking from the number contained in the bin, showing the exact state of the stock at a glance.

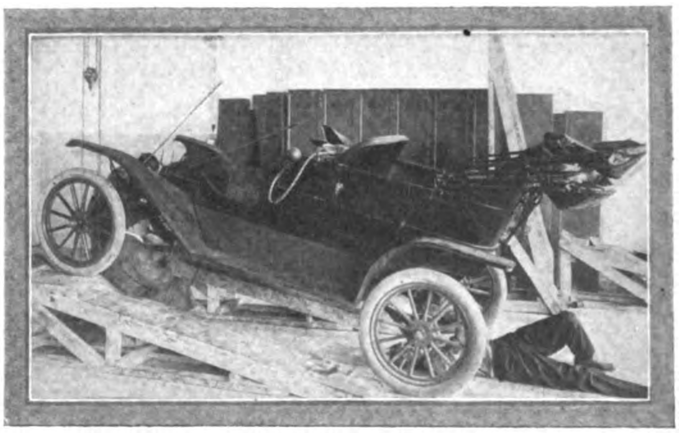
An exact check can be thus kept on stock by comparing the original orders with the cards at stated periods.

There are thousands of these bins in this department, but very many of them contain the complete parts of former models. In fact, parts for the six-cylinder car made by the company several years ago are given considerable space although, of course, the emphasis is laid on the current model. In the bins there are parts for the assembly of fifty complete cars, from top to tires and from taillight to radiator.

The system of handling repairs is not widely different from that in use in other well-equipped plants. The car needing repairs is brought in and inspected. Then the foreman issues an order on the storekeeper for certain parts by number. A copy of this order is kept by the foreman, the original goes to the superintendent and the triplicate is transmitted to the stockroom. The order is filled from the bins and a receipt is taken by the stockkeeper from the foreman.

The records of the superintendent are used as the basis of billing the work, and on a particular job the foreman's order

9—Where the body work is done; a dust-proof varnishing room partly finished is shown at the left



10—Runners used to elevate the front of a car make forward repair work easier

for parts, his bill for time used in his department and other expense bills are assembled under one charge number in the accounting department.

Keeping Track of Labor and Material

In the stockroom are complete parts for all models subsequent to 1904.

On the top floor is the repair department, painting and varnishing department and the department devoted to body work.

The body department is located in front and the repair department in the main division of the floor. In the body department, which is also equipped with a complete plant for painting and structural repairs, is a dust-proof varnishing room. This feature is not quite finished at present but will be in the course of a short time. The idea is to partition off space sufficient to handle two automobiles and by making the walls and interior partition dustproof with heavily woven cloth covering, to furnish a place where the final touches of body decoration will not be damaged by dust sticking to the drying varnish.

A fire door affords entrance to the repair department proper, which is one long room, 175 by 75 feet. On the left after passing the fire door is the place where the automobiles in various stages of repair are quartered. They stand along in a row from one end of the room to the other and at the time of the visit of a representative of THE AUTOMOBILE there were probably a score of cars on the floor. The system of handling repairs is very simple. After the work is laid out and the exact character of the repairs to be made is established the car is dismantled as far as is necessary and the body is given a space in the row.

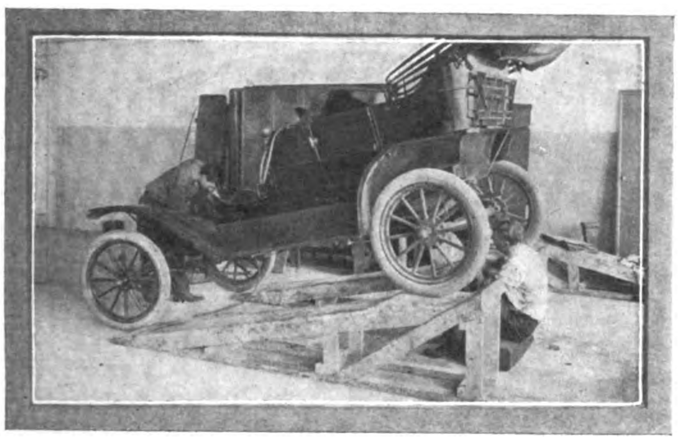
Equipment Seems to Include Everything

If there is to be some structural repair of the body, the damaged parts are removed to the first group of tables on the right side of the floor where vises and woodworking tools are arranged and where several men may work at once. If the motor is to be overhauled and repaired, it goes to the second group of tables and the transmissions are assigned to the third.

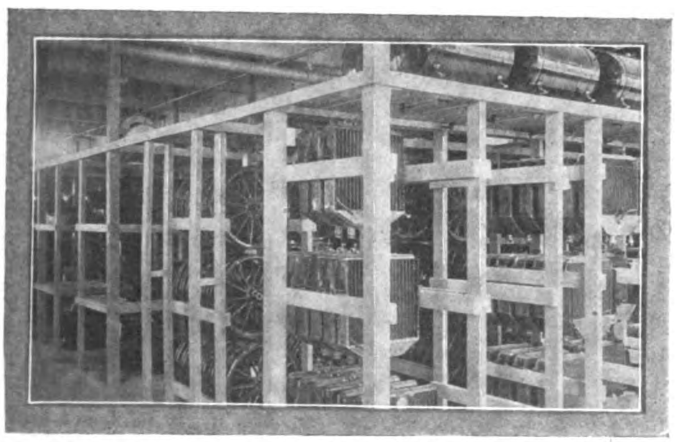
Just after passing the fire door there is a screened room at the right in which the power-driven machine tools are installed. These consist of lathes, drills, press, buffing and grinding tools, shaping and milling tools and constitute a battery of sufficient scope to handle any ordinary work.

There are many little refinements of action in the work performed at the Ford plant. One little device, the invention of the foreman of the repair department, is a pair of inclined runners upon which the car may be placed in such a way as to avoid the necessity of working in very close quarters. The runners raise first the front end of the car and then the rear and by using them access to the axles is made comparatively easy.

The building is as nearly fireproof as any similar building can



11—When the car is reversed it gives plenty of room to work under rear axle



12—Some of the racks containing Ford parts, ready for any kind of a demand

be. Aside from a small amount of paneling and an occasional board here and there for a variety of purposes there is nothing combustible in the plant except the gasoline, oil and the cars themselves. In order to prevent fire danger the building is also equipped with a detailed system of sprinklers with fusible plugs that melt at a low temperature, thus insuring a deluge of water upon any point from which much heat radiates.

There is no big power plant in the Ford Service Building, the boilers and engine room referred to before being an auxiliary. The power plant is represented by a heavy feed wire, over which passes the electric force from the public station.

The sanitary accessories of the building are most complete and ample. Shower baths, comfort rooms and lavatories are distributed through the building.

Railroad Facilities Are Ample

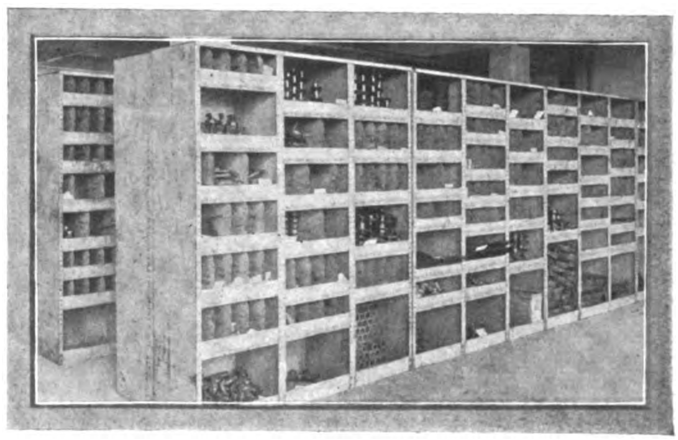
Directly in the rear of the building is the spur track of the Pennsylvania Railroad and back of this switch are the main lines of the Long Island Railroad, all of which simplifies the problem of freight transportation.

It is the intention of the company to maintain a stock of cars at the plant which may be drawn upon in emergencies by dealers, but from the physical characteristics of the building as it stands there appears to be a vastly more significant future outlined.

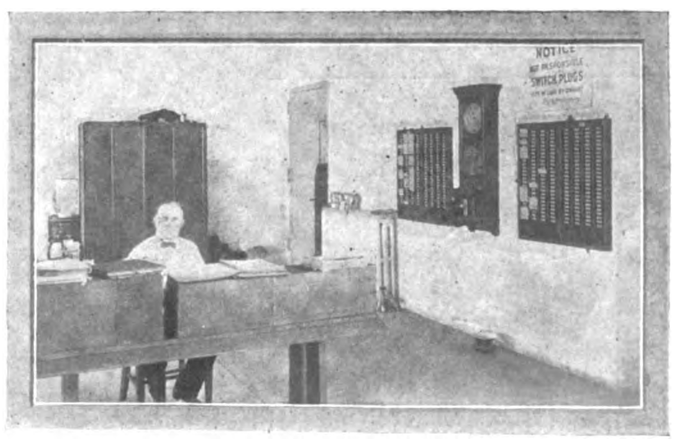
As has been said, the present building can be increased to ten stories on its existing walls and foundations and the fact that only about one-third of the lot is occupied by the building makes future expansion among the probabilities.

If it is in the minds of the company to establish a vast assembling plant on Long Island to supply not only the contiguous territory but also the export requirements, the real estate and building now there would form a substantial nucleus for such an undertaking.

However, at present such a development seems far in the future and the immense building with all its modern fittings will be used to better Ford service. At this stage of progress the plant employs fifteen persons in the offices and seventy in the shop and repair departments. In the immediate future the latter item will be increased to 100 men and if the full capacity of the plant was filled the payroll of the shop force would contain at least 125 names. There are about a score working in the stockroom and a dozen are employed as floormen or demonstrators.



13—Every part, nut and bolt going into the Ford cars is carefully listed and binned as shown here



14—An important part of any commercial enterprise is keeping track of what comes in and goes out

Letters Answered and Discussed

Dressing for Mohair Tops

EDITOR THE AUTOMOBILE:

[2,805]—Would you be kind enough to tell me if you know of any kind of dressing for mohair tops? I would esteem it a favor if you would give this your attention at an early date. F. R. FRIBLEY.

Bourbon, Ind.

Manufacturers of mohair goods and others acquainted with their wearing qualities, etc., advise the use of plain soap and water as a medium for keeping the mohair top in proper condition.

When the top becomes dirty and takes on a "frowzy" appearance brush very briskly with a stiff broom, or wash thoroughly with a solution of castile soap and soft water. Apply the solution with a wool sponge and dry off thoroughly. This is said to be the only safe method of treating a double-texture mohair top with a rubber interlining. The application of oil of any kind, of gasoline or any cleaning preparation is very detrimental to the rubber interlining.

Plain soap and water and the whisk broom are the reliable cleaning and preserving mediums of all mohair fabrics.

Marking the Flywheel

Editor THE AUTOMOBILE:

[2,806]—As I am about to take down my engine to overhaul and clean it, I wish to be sure that I get the timing correct when replacing the valve mechanism. As the engine is at present, the timing is correct, and I have no desire to make any changes in that direction. I am aware that there is a method of marking the flywheel, but do not know exactly how to go about it. Would you kindly give me directions as to how to proceed? AMATEUR.

St. Paul, Minn.

The marks placed on the flywheel indicate the upper and lower dead centers.

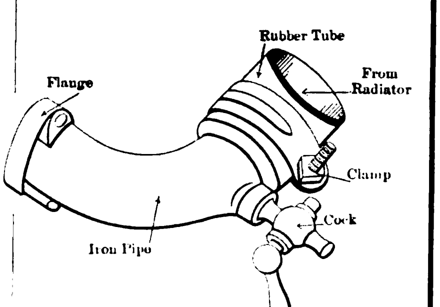


Fig. 1—Showing fitting with drain cock on radiator connection

the position of opening for both the inlet and exhaust valves and of closing for each valve. A piece of sheet brass is cut into the form shown in Fig. 3 and used as an indicator, or a mark is put on the engine base, which fulfills the same office. Chisel marks are then placed on the flywheel, and the initials of the operation indicate what is taking place when the mark registers with the indicator, as, for instance, in the illustration 1 E. O. indicates that the exhaust valve of cylinder number one has just started to open. In the case of several operations taking place at the same time, such as the exhaust for cylinders one and three, opening at the same relative position of the flywheel, the lettering would be 1-3 E. O.

Keep It "Right Side Up"

Editor THE AUTOMOBILE:

[2,807]—Being a subscriber to your journal, I take the liberty to make a query, which I hope to see in an early issue of THE AUTOMOBILE. Would a motor lose any power if the engine were turned upside down so that the pistons exerted their power in an upward direction instead of downward? In this case the crankcase would, of course, be above the cylinders. The lubrication is considered to be perfect. A SUBSCRIBER.

Tiffin, Ohio.

If the lubrication were taken care of the engine would run. After the engine was stopped a pool of oil would probably collect in the cylinder head. We advise running the engine right side up.

Soldering Aluminum

Editor THE AUTOMOBILE:

[2,808]—Kindly give me a receipt for soldering the aluminum base of an automobile. I would like to know where I can buy the special solder or flux necessary for this class of work. CHARLES DEAN.

Queen Anne, Md.

The soldering of aluminum has not as yet been perfected, although fairly satisfactory results have been obtained. Repairs made by the oxy-acetylene and electric welding processes, however, are highly satisfactory. A receipt which has been used to advantage in Germany is as follows: Tin, 80 per cent., and zinc, 20 per cent. The flux consists of 80 parts of stearic acid, 10 parts chloride of zinc and 10 parts of chloride of tin. A solid nickel soldering iron should be used, so as not to discolor the metal.

Fitting Drain Cock

Editor THE AUTOMOBILE:

[2,809]—There is no drain cock on the bottom of the radiator of my automobile. Would you kindly tell me how to install one in such a position that it would be possible to drain all the water off in case I wished to store the machine for any length of time? Any information you could give me on the subject would be greatly appreciated. R. S. STEWART.

Tuckahoe, N. Y.

Where the radiator is connected to a pipe by means of a rubber tube, as is usually the case, a fitting such as that

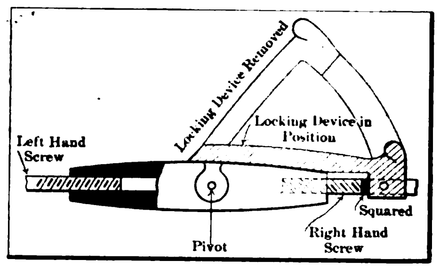

Fig. 2—Illustrating a method used by a subscriber in locking the brake adjustment

shown in Fig. 1 may be purchased, which will have a boss into which a plug or a cock may be screwed, as shown in the illustration.

Locking Brake Adjustment

Editor THE AUTOMOBILE:

[2,810]—The sketch I am sending herewith (Fig. 2) illustrates a locking device which I have installed on the brake rod of my car. I think it is superior to the usual method of fastening by lock nuts. The lock is held in the turnbuckle by means of a pivot, about which it is free to turn. When in position, as shown, it is held by a pin which passes through the squared rod. E. F. S.

Garden City, N. Y.

Desires Names of Cars

Editor THE AUTOMOBILE:

[2,811]—Do you know of any cars being made with planetary transmission, three speeds forward and one backing speed? I would greatly appreciate the names of these cars if you would give them to me at an early date. J. W. MELTON.

Richmond, Va.

We have no list of cars using the type of transmission you describe.

Screen in Intake Line

Editor THE AUTOMOBILE:

[2,812]—I am using a very poor grade of gasoline and find great trouble in completely vaporizing it, especially at low speeds. I have been advised to put a screen in the intake manifold. Would you please tell me how it is done?

CHARLES BEECHAM.

Wellston, O.

It cannot be recommended as highly advisable to place a screen in the intake manifold. The method of inserting is shown in Fig. 4. An indentation is made in each of the two joining flanges, into which the flange which holds the screen is fitted.

An Unexpected Kick

Editor THE AUTOMOBILE:

[2,813]—After having stopped my motor for a few moments I found it necessary to start it again, so I proceeded to crank

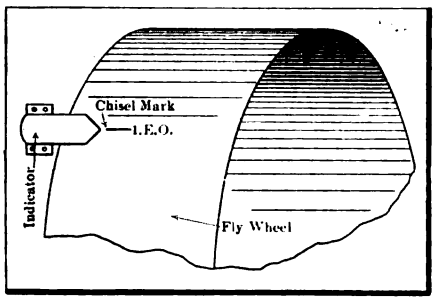

Fig. 3—Method of marking the flywheels of a motor so as to replace timing mechanism properly

it in the usual manner, when suddenly the crank was jerked from my hand and I narrowly escaped painful injury. This is the first time the motor has ever kicked back while being cranked and I would be much obliged if you could give any causes to which it may be due. J. F. S.

Greenlawn, N. Y.

The fact that the motor was cranked right after having been stopped, taken in connection with the probability that you have had experience enough to retard the spark before cranking the motor, tends to show that the cause of your trouble was an overheated cylinder. The overheating was doubtless due to carbon deposits (which may be removed by using a good decarbonizer) or to a projection in the cylinder.

Opinions of an Outsider

Editor THE AUTOMOBILE:

[2,814]—I notice a good deal of discussion in the automobile trade magazines lately in regard to "what is the matter with the automobile trade." It seems that the sales are not what they are expected to be or what they should be. A number of reasons are advanced to account for the conditions, but there are some reasons that are apparent to a person "on the outside" that I have never seen mentioned. I refer to the lack of courtesy and of selling ability in the agencies and branch houses.

It makes no difference how much a car is advertised in the magazines and newspapers if the agencies do not have men with the ability and tact to "close the deal" when the advertisements bring in the "prospect," the advertising does little good. If you will go around to almost any agency or branch and pretend you want to buy a car, you will find that the salesmen are, as a rule, young men who know considerably more about something else than they do about selling automobiles, and questions about details are generally answered evasively (through ignorance), or pertly.

If as much selling ability (to the ultimate consumer) were used in the automobile industry as is used in selling typewriters, adding machines, the cash register, and many other lines of industry, there would not be so much "what is the matter with the automobile trade" discussed in the trade papers. The market for motor vehicles has hardly been entered yet compared to what it will be when manufacturers begin to sell the public what the public needs instead of what they think the public wants, and back their product up by salesmen who can sell the goods. It seems that the extraordinary demand a few years ago gave the manufacturers and dealers an inflated opinion of themselves and they have not recovered from it yet.

Some recent articles in the various automobile trade papers prompted me to write this to give you the views of one who is not connected with the automobile trade, but is interested in the progress of the automobile.

Fort Worth, Tex.

A Leaky Needle Valve

Editor THE AUTOMOBILE:

[2,815]—If you can give me any advice that will help me out of my difficulty I should be very grateful. My car ran very satisfactorily up to a short time ago when it suddenly became very balky on low speeds. The exhaust would emit great quantities of grey smoke and the engine would heat up greatly and then stop. If the motor was run at high speed it would smoke in the same manner and heat up but not to such a large extent as in running up a hill, for instance. I have adjusted the carbureter according to the directions of the maker but that does not seem to overcome the difficulty at all and I am sure that there must be a derangement somewhere.

JOHN EDWARDS.

Scranton, Pa.

The trouble is evidently one of too much gasoline. There might be some particle of foreign matter in the needle valve which holds the same open, or the float may leak if it is hollow. Examine the valve and grind if necessary.

Exhausts Batteries Rapidly

Editor THE AUTOMOBILE:

[2,816]—I have been greatly interested in reading about the troubles of car owners and your answers to them and would like to make an inquiry. I have a small car and for some reason my batteries are continually drained out, although two experts have gone over the wiring and say they see nothing wrong in it. I had a switch put in between the batteries and the timer so that when running on the magneto the batteries could be cut off entirely.

Last year I used about ten sets of batteries and this year have already used about six. Each set consisted of four batteries. I have been very careful not to run on the dry batteries, but have switched over to the magneto as soon as the engine is cranked. I would appreciate your opinion concerning the cause of the trouble.

H. G. VANDEVENTER

Mount Sterling, Ill.

It is very difficult to determine wiring trouble when it cannot be inspected. The indications are that there is a short circuit which might be constant or take place under certain running conditions, or the batteries may be in such a place that they chafe together causing their insulation to wear so that there is a slight contact between them after they have been used for a time. Another source of trouble may be the switch which you have inserted in the line. A switch is very apt to be connected up in such a way that current is allowed to pass through and hence cause the short circuit.

Fitting A Magneto

Editor THE AUTOMOBILE:

[2,817]—I am desirous of fitting a magneto to my car which at the present moment has only coil ignition. Would it be advisable to buy a second-hand magneto?

Chicago, Ill. A. B. S.

It is risky to buy second-hand magnetos as there is no "come back" if anything goes wrong.

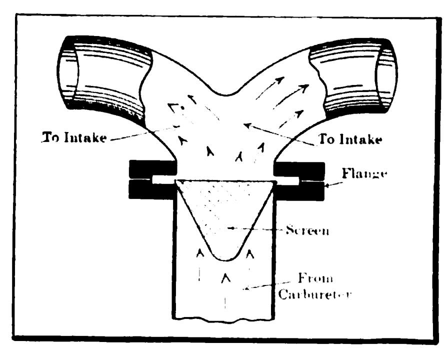

Fig. 4—Showing indentation in flanges so as to form a place for the supporting flange of the screen in the intake manifold

My 1912 Automobile

Some Conceptions of What the Ideal Car Should Be

The invitation to our subscribers to describe their ideal 1912 car has struck a popular chord. The responses show a wide appreciation of the salient points of car design and a knowledge of the points which tend to reliability and comfort. THE AUTOMOBILE *hereby continues the invitation to its readers to mail in their conception of the features which should be embodied in next year's car. The information given should include such points as:*

Horsepower	*Clutch*	*Tire sizes*	*Equipment*
Bore	*Gearset*	*Rear Axle*	*Cylinder type*
Stroke	*Drive*	*Front axle*	*No. of cylinders*
Ignition	*Springs*	*Control parts*	*Cylinders, how cast*
Lubrication	*Wheelbase*	*Body features*	*Price*
Carburetion			

In addition to giving these details the reasons for your points of selection should be stated concisely and clearly.

As a benefit in the matter of comparison some details of the average cars for 1911 are given below.

Each communication must be legibly written on one side of the paper only; it must be properly signed with the writer's full name and address, and if the writer does not wish his own name to appear in print he may request the use of any nom de plume.

Any reader desiring to make line drawings, showing details of his ideas of his car or some of its parts, is requested to do so.

Editor THE AUTOMOBILE.

DETAILS OF AVERAGE 1911 CARS WHICH WILL ENABLE READERS TO MAKE COMPARISONS IN DISCUSSING 1912 MODELS

	$1,000 *and thereabouts*	$1,500 *and thereabouts*	$2,500 *and thereabouts*	$4,000 *and thereabouts*
Horsepower	20.5	29.525	35	43.66
Bore	3.98 *inches*	4.19 *inches*	4.40 *inches*	4.875 *inches*
Stroke	4.12 *inches*	4.64 *inches*	4.98 *inches*	5.39 *inches*
Wheelbase	100 *inches*	114 *inches*	119 *inches*	124 *inches*
Front tires	31.4 *x* 3.3	33.1 *x* 3.8	35 *x* 4	35.7 *x* 4.27

Clutch	*Disc*	*Multiple disc*	*Cone*	*Multiple disc*

Wants Conservative Design

EDITOR THE AUTOMOBILE:

Having driven and cared for several moderate-priced cars in the past few years, and having thereby gained some insight concerning their defects and good points, I herewith submit my idea of a car that would appeal to the owner-driver, of moderate income, and could be sold at about $1,200.

First, considering the power plant, the motor should have four cylinders, with the cylinders cast singly, if possible, or if not, in pairs, but never en bloc, as accessibility is of prime importance to the owner who cares for his own car. Another objection to the en bloc type of casting is the limited amount of bearing surface for the crankshaft. The bore of the motor should be 4 inches and the stroke 5 or 5 1-4 inches, the long-stroke motor permitting greater power at slow engine speeds, thereby reducing gear changing in congested sections and in hill climbing. There are practically no long-stroke motors used in any of the moderate-priced cars, the manufacturers evidently not wishing to assume the expense of designing new tools and fixtures to replace their regular models, in which the stroke in very few instances exceeds the bore more than 1-2 inch. The valves should all be on one side, being of slightly larger diameter than at present and given ample lift to develop the full power of the motor. Each valve spring and push rod should have an easily detachable aluminum casing of cylindrical shape, to protect valves from dust and deaden the noise.

Ignition should be by storage-battery and generator, with one of the systems of spark distributor now on the market, and this equipment would also take care of the lighting of the car and would not be any more expensive than the combined cost of the magneto, coil and gas tank. The dynamo would, of course, keep the storage battery always charged to its capacity, thereby making for long life for the battery. The motor should be water-cooled by the thermo-syphon system, the inlet and outlet manifolds being made slightly larger than at present to insure perfect circulation. The radiator should be large enough to perform what is expected of it easily. As nothing adds to or detracts from the appearance of a car so much as the style of the radiator, care should be taken to make this of as neat a design as possible, preferably square tube.

The motor should have a self-starting device, as no car is complete that obliges the operator to leave his seat to start the engine. The system by which gasoline is pumped to the cylinders and the engine started by turning on the switch offers the simplest and least expensive way to obtain this result. The motor should be fastened to the frame at three points, in such position that it is entirely under the hood, so that any cylinder may be removed or any adjustments made without interfering with the dash or body of the car.

The transmission should be by sliding gears, selectively controlled, the gearcase being mounted on the rear axle assembly, while the control levers are in the center and the steering wheel on the left-hand side. There should be three forward speeds and one reverse; the reverse should be at least as fast as the lowest forward speed. In this day of flexible motors it is easily possible to run a car backward slowly enough, even if many of the reverse speeds were double what they are at present. The reasons for the left-hand steering wheel are so obvious that I will not dwell upon them. The steering gear connections should be so made that, even if worn excessively, it will be impossible for the ball joints to drop from their sockets. The front axle should be of the I-beam type. The frame should be double-dropped, as 10-12 inches road clearance is quite sufficient, as the low center of gravity obtained by the dropped frame is particularly desirable, since it eliminates skidding to a large extent, making it practically impossible for the car to "turn turtle."

Wheels should be strongly made, with Q. D. rims, and tires 36 by 4 inches all around. Springs should be semi-elliptic in front, three-quarter elliptic in rear, with shock absorbers included in the design so proportioned as to work in harmony with the springs. By this means much could be added to the comfort of the passengers. This would be appreciated greatly, as at present most of the cars of moderate weight are notoriously rough-riding when they are used on other than smooth roads.

The wheelbase should be about 112 inches and the body designed with a view to comfort, the backs of the seats being high enough to insure this quality. Not a few manufacturers, desiring to obtain a low, rakish, straight-line effect, have lowered the backs of the seats so that touring in these cars is always accompanied by weariness. Comfort and easy-riding qualities are almost as important as mechanical perfection, while appearance should be subordinate to both, for it is easily possible to design a good easy-riding car to look as well as some of the bone-shaking creations designed to afford a racy appearance.

In almost all five-passenger cars of 110-inch wheelbase or more the front seat is crowded close to the dash, while quite a lot of room goes to waste in the tonneau, between the rear seat and the back of the front seat. This space could be utilized to good advantage by slightly lengthening the space allotted to the front compartment. By thickening the back of the front seat slightly, a compartment could be made to accommodate the extra shoe, there being a hinged cover over this compartment. The body should have doors in front, and these doors should be readily removable.

For a moderate-weight car the semi-floating type of rear axle is quite efficient, the full-floating type not offering sufficient improvement to warrant the extra expense. The gasoline tank should be sufficiently above the carbureter to insure perfect feeding when climbing steep hills. The carburetor should be the best that money can buy. No manufacturer should equip his car with a cheap carbureter, for even the highest priced and most efficient carbureters are relatively inexpensive, and the difference in price between a good carbureter and a poor one does not atone in the slightest way for the action of the motor equipped with the latter, when compared with how it would act when equipped with the former. No motor is better than its carbureter.

The weight of such a car as I have described ought not to exceed 2,800 pounds, and by liberally using vanadium steel and aluminum fittings where possible, could probably be kept down close to 2,600 pounds. All exposed bright parts, including all lamps, wind-shield, etc., should be enameled. The owner-driver who cares for his own car does not want to spend half his time polishing brass.

There should be no traps of any kind on the running boards, but a compartment having doors should be built integral with the back of the rear seat. In this compartment would be places for luggage, shelves for tools (each tool having its individual place) and room for storage battery, thus permitting the entire space under the front seat to be used for gasoline tank.

In summing up, the main points for improvement are longer stroke motors, more accessible motors; easier-riding cars, secured by larger wheels, and properly designed springs and shock absorbers rather than excessive weight; more comfortable seats; more room for driver; higher grade carbureters; self-starting devices, and compartments to carry all accessories, thus eliminating all traps from the running boards. In conclusion I would state that all manufacturers should design their own tops and windshields to especially conform to the particular model, and always fix their price to include same in equipment of car.

A. H. Silver.

Red Lion, Del.

Idea of Popular All-Around Car

Editor The Automobile:

In your issue of the 24th inst. you invite contributions from your readers as to their conception of what the 1912 car should be. I am only a car owner who drives his own car, but I have been a student of the automobile industry from the beginning, and I believe the description I give below is of a car that would prove universally popular and would give excellent service under practically all road conditions.

The motor should be six-cylinder, 4-inch bore and 6-inch stroke, cast in pairs, with open water jackets and bolted together, giving an en bloc effect, but giving the benefit of separate castings; cylinders should be T-heads, all valves enclosed; flywheel and fan combined; the pumps and magneto should be mounted on a cross-shaft at the front of the engine, allowing ample room to get to crankshafts through side plates on crankcase. Engine base and case should be cast with web so as to abolish the mud pan. The engine bearings should be four in number and of large ball-bearing type. The engine thus described will be practically 40 horsepower under S.A.E. rating, but would no doubt really develop 50 horsepower under brake test, and would be amply powerful.

The ignition should be double. There is really no virtue in dual ignition. If the magneto is all right the car can be cranked on the magneto; if the magneto should have something wrong with breaker box mechanism the battery is also out of use. The oiling system should be crankcase circulating, with sight feed on dash and with a glass float gauge on crankcase.

The carbureter should be constructed so as to have a gasoline adjustment on the dash. The clutch should be multiple-disc with not less than 51 discs, and run in oil.

The gearset should be carried amidships, or might be installed as a unit with the clutch, or the fan might be of the coventional type, but shaft-driven, and the engine, clutch and gearset installed as a unit. The gearset should be four-speed, direct on third.

Springs, semi-elliptic in front, 2 x 40; rear three-quarter elliptic, and 2 1-2 x 45 inches.

Shaft-drive with two universal joints and tension rod, should be nearly straight-line drive.

Wheel base, 116 inches, which will give ample room in body for a four-passenger car. The frame should be pressed steel, double drop and inswept at front to permit of turning in the average street.

The steering should be of the irreversible type, with large steering wheel; connections all above front axle. The radiator should be of real honeycomb type and should be hung from trunnions on the side frames.

Tire sizes should be 36 x 5 all around, and should be on demountable quick-detachable rims.

Front axle should be drop-forged I-beam with integral spring perches; the rear axle should be full floating and wheels bolted to brake drums.

Spark and throttle control should be on top of steering wheel, and both moved upwards for advance. Also should be foot accelerator. Should be double brakes on large drum 17 x 2-1-2, internal and external, both equalized; foot pedal for service brake, with cam arrangement so that farther depression will apply emergency brake also, thus doing away with emergency lever. A patent has been allowed on a practically automatic gear-shifting arrangement that is destined to revolutionize gear shifting on pleasure cars. This will do away with the side shifting lever, transferring its duties to the automatic arrangement, allowing the steering wheel to be continued on the right side of car and allowing free entry from both sides of the car. The clutch pedal to be the left-hand pedal, which follows the almost universal practice.

This car should be built to weigh not exceeding 2,600 pounds. The body should be of fore-door type, with ventilators, front seats divided purposely to prevent more than two persons on the front seat. A pocket could be inserted in the division between the seats and every advantage taken to have the car convenient and comfortable. The upholstering should be the smooth finish because it lasts twice as long as tufted, though not quite so comfortable.

Equipment should be absolutely complete, self-starter, electric lights, top, top boot, windshield, hand horn, cut-out, license hangers, robe and foot rails, magneto, shock absorbers, bumper, tools, some form of inflating tires, speedometer, demountable Q. D. rims, one extra rim, tire hangers and trunk rack.

If one of the reputable manufacturers would undertake to put this car out with a guarantee for life of car, in my opinion they could make a handsome profit at a price of $2,500 and would get orders for the entire output within sixty days from their announcement, but it would be folly for any of the newer and less known manufacturers to undertake its production.

Robt. N. Hughs.

Atlanta, Ga.

Little Bits of Motor Wisdom

Pertinent Pointers for Repairman and Driver

A series of short stories that will tend to keep the automobilist in touch with matters mechanical and otherwise, covering a field of information that although usually well tilled, needs frequent and careful cultivation to produce the greatest results.

WHEN USING ROLLER BEARINGS—In the effort to get away from sliding contact and its consequent loss of energy in friction one of the modern methods which has found favor is the use of roller bearings. Instead of the metal sliding over a plain metallic face it rolls over a series of small steel cylinders which are arranged as shown in Fig. 1. They are free to turn about their own axis so that the amount of bearing surface is very much reduced, being resolved down to a series of lines. The rollers are of course kept out of contact with each other as, if allowed to touch, their tendency would be to turn each other in opposite directions instead of in the same direction as they would do if performing their ordinary function.

An interesting feature about this type of bearing is the fact that the bearing surface instead of being a plane as is usual in any sort of bearing, consists instead, of a series of lines which are capable of taking a large amount of weight. The roller bearing has met with great success where used upon long axle bearings, where great weight has to be supported. In this case the great reduction in friction is very evident as the line contact has great advantages over surface contact under these conditions. Lubrication is well contained in these bearings and hence it is comparatively easy to keep them in good condition. The friction in a bearing depends to a large extent upon the surface exposed. This fact is brought out well in the observation of a wagon in comparison with a drag sledge. The wagon is much more easily drawn than the sledge because it is supported at two or four points while the sledge has a considerable area which slides upon the ground. Where there is a very large weight to be born, as at the wrist pin of the engine which receives the whole force of the explosion in the cylinder as it is transferred through the piston, the plain bearing is the safest to use. The frictional losses in the wrist pin do not amount to much however as the contact is merely oscillating, and since it is impossible to get such an adjustment where there is no lost motion whatsoever at this point the bearing surface is theoretically the line of contact between two cylinders, *i. e.*, the wrist pin and the bearing bushing.

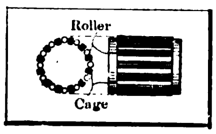

Fig. 1—Showing a roller bearing with the rollers and cage indicated.

HOSE CONNECTIONS OFTEN CARELESS—It is, on the whole, rather unsatisfactory to join the water manifold to the radiator carelessly. It is necessary that the joint be carefully made and is absolutely tight. A small leak in the joint will be responsible for the loss of much of the cooling water and since a new supply is not always available, overheating of the engine may result owing to the lack of a sufficient quantity of water in the system. Temporary repairs can be instituted, but when made, should be followed up as soon as possible by a repair which will hold. The method of clamping is illustrated in Figs. 2 and 3 in which either a semi-circular or a circular metal band is placed about the tube and a clamp bolt put in the position shown.

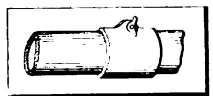

Fig. 2—Type of clamp joint used to advantage in pipe fitting

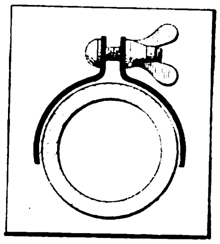

Fig. 3—Showing the winged nut on a clamp joint. This is a handy means of connecting the radiator and tubing.

ALMOST UNBELIEVABLE REPAIRS CAN NOW BE MADE—With the great advances in the knowledge of the oxy-acetylene welding processes the parts that were often thrown away or relegated to the junk pile or scrap heap can often be repaired. This knowledge will save the automobile owner who has been wont to purchase a new casting whenever cracked or broken parts have given trouble. In case of a break, the principal thing to remember is to save the parts, it will save expense.

In the case of a cracked water jacket the crack is first laid open by a partial heating until the full extent of the damage is determined. In case of a very thin crack which will not open up to any extent even under the influence of heat, it is necessary to chisel the opening so that the metal from the melt bar can be run into the crack thoroughly and fill it up solidly.

The oxy-acetylene process leads all others in use for repair work where all sorts of odd jobs are encountered. It is easily carried to different parts of the repair shop and may be controlled readily by the operator, by means of the cocks on the handle. The oxygen and acetylene gas are supplied in cylinders which are renewed when empty, the tubes are attached to these tanks and the gauges are also placed on the line near them. The oxygen is taken from the tank at about 25 pounds to the square inch while the acetylene has a pressure of six to eight pounds. The part to be treated is placed in a charcoal fire and heated up to a dull red heat. This is especially necessary in the case of cast iron as it is very liable to crack after or during the operation if this precaution is not taken, owing to the unequal expansion of the metal.

After the heating has been carried out the burner is taken and the acetylene gas turned on alone, after which the oxygen is turned on until the required flame is given. The flame will vary with the nozzle which is being used. This nozzle is adapted to the work in hand, and it is one of the characteristics of an experienced man in the art of welding to be able to choose the proper tip. The flame is directed around the gap in the metal until it runs, whereupon the melt bar is placed into the aperture and allowed to melt in with the other metal until they are joined so that they become one. When welding the gray iron used in cast cylinders a flux powder of alkaline tendencies is used to bring all the impurities to the surface, so that a strong joint is made, which would not be the case where the weld was filled with impure material.

Different metals require different treatment; steel, for instance, should be hammered on cooling and then, if possible, annealed. A steel which is high in carbon will suffer in the welding process. When welding two metals of different natures together it is necessary that the melting points be within fairly good range of each other in order to get good results.

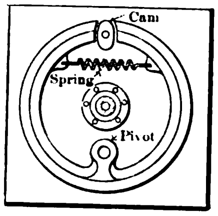

Fig. 4—Illustrating an internal expanding brake with the relative positions of the pivot and spring shown.

INTERNAL EXPANDING BRAKES—The internal brakes are of the expanding type, that is, they are forced against the brake drum by expanding the circle which is bound by the shoes. The brakes are called internal from the fact that they bear against the inside of the brake drum and are so enclosed that grit and dirt cannot readily enter. The expansion is effected by a cam as shown in Fig. 4, which illustrates a brake of this type. When the cam is turned the shoes are spread apart by swinging about the pivot indicated in the figure just mentioned. An important part of the device is the spring which is shown in position; it is installed so that when the pressure on the pedal is released and the cam returns to its original position the brake shoes will not continue to bear against the drum, but will be pulled back to their normal state. A stop is placed so that the shoes cannot go back so far that there will be any lost motion in applying the brake pedal, or, in other words, that the brake shoes will bear against the drum as soon as the pedal is pushed down a very slight amount.

The greatest cause for rapid wear in a brake is the entrance of some gritty material between the shoe and the drum which will cause the brake to heat to such an extent that it will "burn out" leaving the material in a condition which greatly tends to rapid wear. This is an accident which is much more apt to occur in an external brake than in an internal as it is not so easy to cover them properly, but if the external and internal brakes act upon the same drum, if the drum becomes overheated from either shoe it will naturally affect both brakes.

CORRECT VALVE TIMING—In a four-cycle motor of any type or number of cylinders the exhaust valve should be opened long enough before the end of the stroke to allow the pressure to have dropped to about atmospheric before the piston has traveled any great distance on the succeeding upstroke. The exhaust valve should remain open as long as possible, not closing at any rate until the end of the exhaust stroke and generally after the flywheel has traversed about five degrees past the upper dead center. The inlet valve should not open until after the exhaust valve has closed and should remain open for the whole suction stroke so that the full weight or charge is drawn into the cylinder.

The timing of the valves depends to a large extent upon the speed of the gases on entering and leaving the cylinder. This speed is, for a given pressure, determined by the size of the port and the lift of the valve, so that for a relatively small port and slight lift the valve will have to open early and close late. Another factor in determining the timing of the valves besides the area of the ports and the lift of the valves, in relation to the volume of the cylinder, is the speed of rotation of the motor. In automobile motors which are generally of the high speed four-cycle type it is very usual to have the exhaust valve open forty degrees before the completion of the impulse stroke. This corresponds to about 7 inches on the flywheel in the case of a flywheel 2 feet in diameter, or, in any case, it will be one-ninth of the circumference. When the exhaust valve is opened as early as this it is not closed until relatively very late, that is, at about five degrees past upper dead center or occasionally as much as ten degrees. Five degrees would correspond to seven-eighths of an inch on the 2-foot wheel referred to above.

It must not be supposed that when it is mentioned that a certain function has a lead of so much over dead center or a lag of another quantity that it means that any great portion of the stroke is referred to, as the angularity of the connecting rod enters into the problem, and in the case of ten degrees past dead center on the flywheel only a little over nine-thousandths of the stroke, or with forty degrees about nine one-hundredths of the stroke. It is not a very profitable undertaking as a rule for the amateur to attempt to change the timing of the valves on a new automobile as soon as it arrives from the place of purchase; it is a fact, however, that a gain in power will result from a change after the motor has been in use for a length of time and has settled down to its work. It occasionally happens that a machine which, while not mis-timed, has not been set so that the greatest power possible is being derived; in this case it is possible to accomplish a gain by a series of carefully observed trials with different valve settings. It is of great importance that these trials be run off in logical sequence.

SLOVENLY WIRING—When it is such a simple matter to hold the wiring of the motor in such a position that it will not jump all over the engine in a series of wild gyrations while traveling along a rough road, it is a great indication of either laziness or something else of similar nature on the part of the driver. A small T-shaped attachment as shown in Fig. 5 will do away to a great extent with the apparent desire on the part of the wires to jump through the hood.

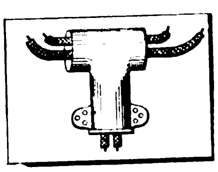

Fig. 5—T-fitting which may be used to hold wires so that they will not chafe

The fitting may consist of an ordinary T-pipe joint to which has been brazed a small flange for holding purposes. The wires are passed through the lower part of the T and out through the upper branches, whence they are conducted to the cylinders to which they belong. This will do away with any possible chafing which will be very apt to exist if the wires are allowed to fly around loosely. Another result of loose wiring is that in its working about it will tend to bend to and fro at the binding posts. This will inevitably result in its fracture. The wire itself may break within the insulation and a thing of this kind is exceedingly difficult to locate as the spark will be perfect when the wiring is in some particular position while if moved slightly it will throw the ends of the wire out of contact and cut off the spark from that particular cylinder.

SIX-CYLINDER FIRING SEQUENCE—If a variance of the order of firing in the different makes of six-cylinder cars may be taken as an indication, there has not as yet been any definite law evolved in regard to this matter. The wiring of the batteries and magneto are fairly well standardized and usually takes the form of that shown in the accompanying wiring diagram, shown in Fig. 6. The most marked difference in any case so far as the wiring is concerned will be the order in which the contact maker will send a current through to the succeeding cylinders. If the cylinders are numbered as shown in the cut, it may be interesting to note the order in which some of the leading makers of six-cylinder

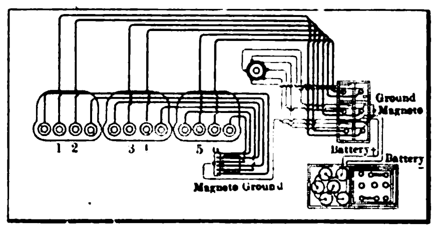

Fig. 6—Illustrating typical wiring diagram of six-cylinder motor

motors arrange their ignition. We will consider eleven makers. Of these eleven, five fired in this order: 1-4-2-6-3-5, three fired as follows: 1-5-3-6-2-4, and the others, 1-2-3-6-5-4, 1-3-2-6-4-5 and 1-3-5-6-4-2.

There are many factors which enter into the determination of the firing order, the greatest being that of getting the gas into the cylinders with as uniform distribution as possible. A manifold of a given design may give widely varying results when the firing takes place in different orders of sequence. It will be noticed that the largest percentage seems to be in favor of not allowing two succeeding cylinders to fire in succession. It is very important that the compression in each cylinder of a multi-cylinder motor should be equal, so that each crank receives the same turning moment. This is in reality much more important in most cases than the order of firing.

Cooling Troubles—Their Symptoms

Overheating Results from a Variety of Causes

The cooling system of a car should be as carefully watched as any other part of the mechanism. Trouble is not always directly due to carelessness on the part of the driver, as poor design may be the guilty factor; however, it is often the indirect result of neglect on the part of those to whom the car is turned over after leaving the hands of its makers.

STARTING with the radiator and following the cooling system through its various phases, it is seen that there are a number of causes for the overheating of the motor, any one of which may give rise to at least several of the others since they are, to a large extent, dependent upon each other. For instance, if the fan is deranged so that the water in the radiator is not cooled sufficiently, it will lead to the deposit of scale on the walls or in the cells, due to the increased activity of the chemical agents within the water under the influence of the greater heat.

There are two types of fans which are in general use, that in which the fan is formed by the vanes of the flywheel and that in which it is driven off a belt from a wheel which is actuated by a reducing gear. In the case of the former, it is necessary that there be no leakage of air past the radiator, and in order to prevent it, the air is confined by means of a tight hood. The first cause of trouble is that the air finds other and easier methods of getting through to the fan than by means of the radiator. This cuts down the cooling ability of the radiator, since it is directly dependent upon the amount of air which passes through it in a given amount of time, so that in case where this type of fans are used the air-tight hoods should be inspected. Where the second mentioned type of fan is used the greatest troubles will be in the nature of its not being driven at sufficient speed, or that it has been twisted on its bracket so that it has come out of alignment. In this case the resulting noise would soon lead to its detection. Occasionally after a belt has been used for a length of time it will stretch so that there will be a larger percentage of slip which will have to be taken up. This can be tightened by means of the adjusting device or by cutting the belt and inserting a new connection.

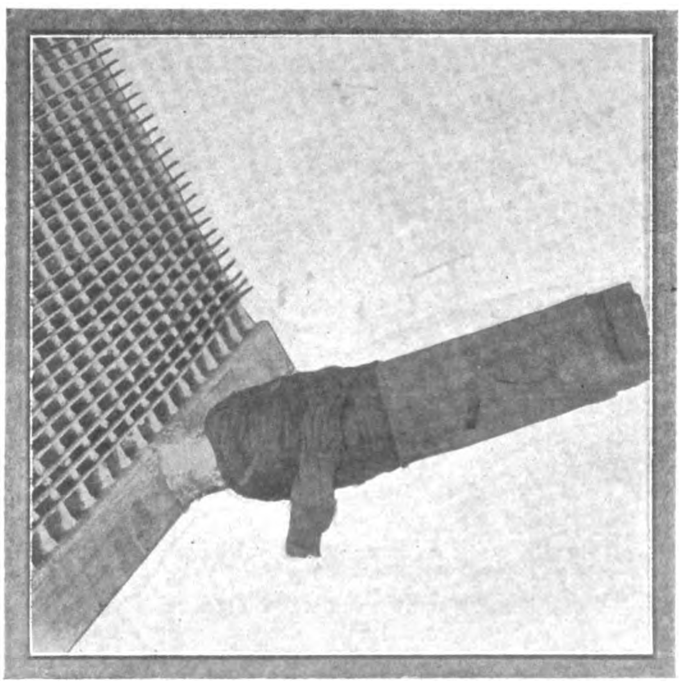

Fig. 1—Illustrating a temporary repair made on a hose connection, which, while satisfactory for a short time, should be immediately replaced by a permanent repair

Fig. 2—Method of making a tight connection between the hose and the radiator. A metal clamp is fastened in place with a small bolt

The greatest damage to the system is caused by the various kinds of obstructions which clog the tubes and interrupt the circulation. The obstructions in the radiator are generally caused by deposits due to the use of impure water, while those in the other parts of the system are caused by imperfect pipe fitting or by foreign matter in the piping. The best way to keep out of radiator trouble is to use the proverbial ounce of prevention and wash the radiator frequently, both on the inside and outside, and in case the only water procurable is known to be very rich in calcium carbonate or calcium sulphate or any of the magnesium salts, some form of scale preventative of a chemical nature may be used which will go far in preventing the formation of scale. Water which contains these salts of calcium or magnesium to any extent is commonly classed as hard and may be detected by its inability to form a lather with soap. It may be remarked right here, however, that it is exceedingly dangerous and inadvisable to experiment with the many detergents which are on the market, as their action on the metal of the radiator is highly corrosive, unless it is absolutely necessary. Ordinary care and the occasional flushing out of the radiator with a small quantity of soda will generally keep it in good condition.

When the obstruction is in the water piping it is apt to be caused by careless fitting more than from any other cause. Where there is a pipe joint in which it is necessary to maintain absolute tightness there will be a gasket inserted to hold the joint tight. It is not an uncommon accident to have this gasket squeezed into the pipe so that it will choke the bore to such a degree that the capacity will be very largely cut down. In this case overheating will be a natural result and the case will be a most puzzling one, for no amount of radiator cleaning will remedy it, and the driver is very apt to think that the trouble lies in the carbureter adjustment or some other part of the mechanism which may be in a state of perfect adjustment. It is impossible to detect the defective washer or gasket until the piping is taken apart and inspected.

In the case of a thermo-syphon system the most common fault is not due to the carelessness of the driver as a rule, but to a lack of foresight in the design. This defect is that of not allowing the water in the cooler to be a sufficient height above the point at which the water re-enters the tank after having passed through the system. The water is circulated to a great degree by the steam generated above the top of the engine

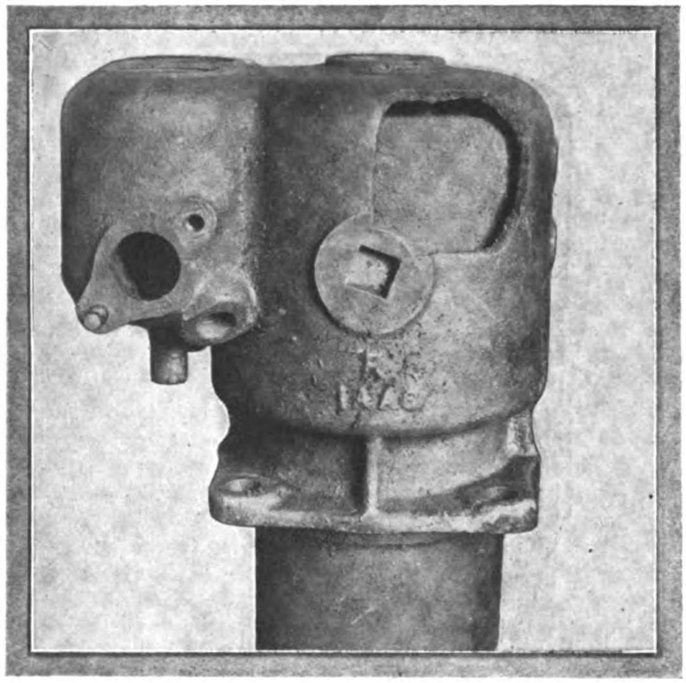

Fig. 4—Broken water jacket which can be welded by the oxy-acetylene process if the missing part is not lost

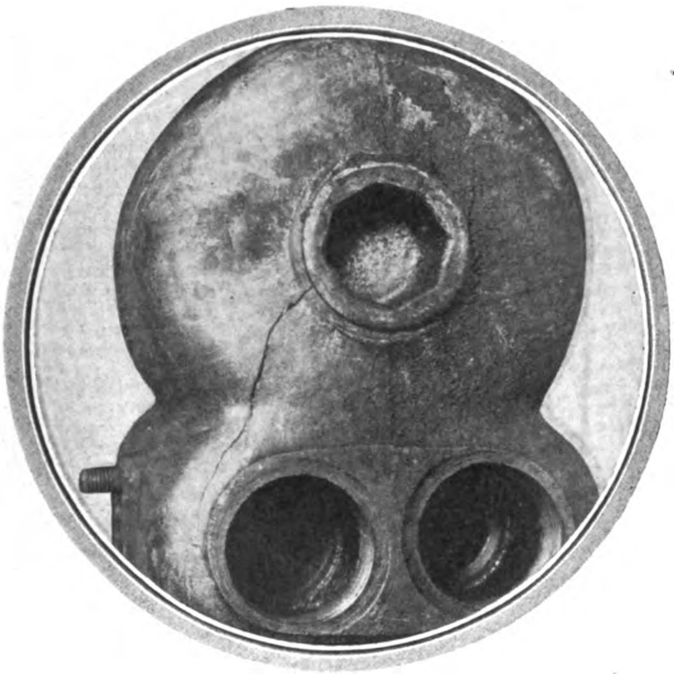

Fig. 3—Showing a cracked water jacket which will allow the cooling water to run away

cylinder at the point of outlet from the waterjacketing; the flow, however, to be satisfactory, must be continuous and this is impossible if the water falls below the tube which carries the water into the cooler so in order that the water will not drop below this level after having run for a comparatively short distance, it should be a matter which is well attended to by the designer. He should be careful that the filler opening is at a good height above the top of the cylinder.

The matter of foreign material in the piping and waterjacketing is largely due to the same causes as those which have been named for the deposits of scale in the radiator. The deposit is to a great degree lime, although there is always a large amount of other matter present. The deposit will gradually accumulate, getting worse and worse until, if not attended to, it will very seriously affect the circulation and hence impair to a great extent the cooling of the motor. A reliable remedy for this as well as for the radiator trouble is hot soda, although there are several patent solutions for sale which are no doubt very good.

The water pump is very seldom the cause of any great trouble in the way of cooling, as a centrifugal pump, which is the type in general use, is so simple that it is not very liable to get out of order in such a way that it permanently cuts off the water supply. The packing might start to leak or the pump may not be driven fast enough, but the former is merely a matter of adjusting the stuffing gland, while the latter is not very liable to ever happen since the correct speed of the pump has been determined in its relation to the engine speed.

The matter of small or contracted piping is another feature which if it were present would seriously affect the cooling system. The piping of a motor is, as a rule, designed to be of ample size to permit the required quantity of water to pass through at the correct velocity. It may be easily seen how a contraction in any part of the piping system would change the whole scheme of flow. The velocity of the water in any part of the pipe must vary inversely with the diameter of the pipe since the same quantity of water must pass through each section in a given time. Hence, the amount of water passing through the pipe in a unit of time would be governed by the amount which passed through the smallest opening in that length of time. If the piping is constricted by an indentation of more or less severe nature the required amount of water will not be circulated through the jackets and the motor will be bound to overheat.

It is, of course, very obvious that a leak in the water system will be responsible for the overheating of the motor. In this case it is not the leak which is directly responsible but the lack of sufficient water due to its having been wasted by flowing from the pipe in which the leak is taking place. Besides being in the piping the leakage may be due to a cracked waterjacket or to a punctured radiator. In the case of the piping it is very often the case that a slight leak has been repaired by the owner in an inadequate manner. An illustration of this is given in Fig. 1, in which tape has been roughly wound about the rubber tubing at the point where the water is taken from the radiator. This repair was no doubt made upon the road and intended to hold the joint until a repair shop was reached. This is often done, the only trouble is, however, that the owner generally neglects to go to the repair shop with his car after having made the temporary repair, but thinks he will take "just one more spin" before the repair is made. Many a time has the owner of a new car, or perhaps more often the new owner of an old car, started for the repair shop with the firm, but often reluctant intention of having a few minor repairs made. The temptation gradually steals upon him to "hit her up" a little before putting the car into the tender hands of the repairman and, as a result, in a short time the driver finds himself far beyond the confines of the town with the motor perhaps running well and the temporary repair, to all appearances, as good as new. He may get through with it, but in a large percentage of cases he finds himself behind a two-horsepower country wagon trailing leisurely along by means of a rope. Human nature is naturally bound to assert itself, but incidents such as the above could, to a large extent, be eliminated by the installation of a few tools and a repair bench in the garage. The method of repairing a leaky hose joint is to cut off the worn end and fit a clamp as shown in Fig. 2. In case the hose cannot be cut off a new section will have to be purchased and the end fastened with the clamp as shown in the illustration just mentioned. It happens sometimes, though happily very rarely, that the lining of the rubber tubing used in this part of the system works loose and acts very much like a non-return valve in that it would allow the water to flow in the opposite direction, while it is washed across the hose by the water in its flow, thus sometimes closing the tube entirely. This is a very elusive mishap to locate and will often give a great amount of trouble, as the indications are the same as any other clogging and no one is apt to suspect the short piece of rubber pipe which, nevertheless, is at the source of the trouble.

When the water goes above the boiling point, which is about 212 degrees Fahrenheit, steam is given off which will cause trouble in many ways. The resulting expansion due to the latent heat of steam will give a pressure in the waterjacketing far above that ordinarily encountered. This will often find its way back into the pump and cause trouble. It may be detected by the steam which escapes from the radiator cap and other joints in the water system. When there is insufficient water in the system boiling will result and, as has already been stated, a deposit of lime with its accompanying evils will be the result. Another difficulty which, it may be happily stated, is not as common as it was at one time is the presence of air locks in the circulating system. This was caused by having large vertical reverse bends in the tubing or connecting pipes, and may be classed as a first cousin to that other trouble of somewhat the same nature, namely, that of kinks in the hose connections.

A note of warning often sounded but as frequently unheeded is to be careful that after cleaning a taken-down motor all the cotton waste is to be carefully removed and even the threads which are so frequently left upon a rough surface after having wiped it with waste are removed. These stray threads have the unhappy faculty of picking out the most pernicious spots in which to collect and clog small but important openings. Rags are often as bad in this respect and it is of great importance that care be exercised in removing any material of this nature to avoid unexpected trouble later on.

Water should not be left in the radiator or jacketing if the car is going to stand in a place where the water will freeze. In very cold weather it should be removed or else a good anti-freezing solution added to the water. The results of carelessness in this respect are a cracked water jacket as depicted in Fig. 3, or in severe cases a break such as shown in Fig. 4. While these breaks can be welded, they are very nasty things to handle.

The illustrations herewith are taken from photographs which were secured by the courtesy of the Haynes Automobile Co., 1715 Broadway, New York City, who extended the privileges of their repair shop.

Tires and Rims

Tires are the means provided of transmitting the power from the motor to the road surface, and in a large degree the pleasure derived from a day's drive depends upon the amount of trouble given by the tires.

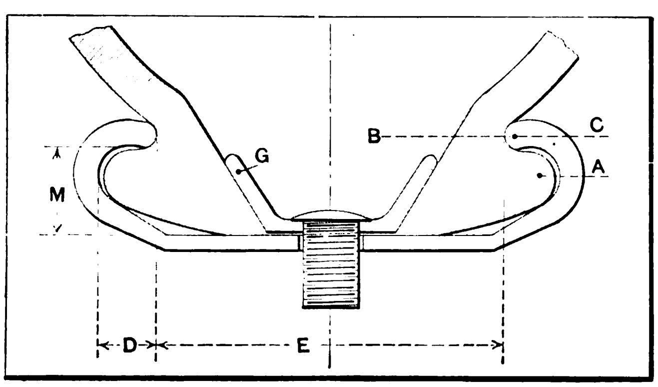
AUTOMOBILING is nearly always exhilerating and as tires play such an important part it is a wonder owners do not pay more attention to them. There are certain things that the amateur has to be told in order that he may appreciate the service that certain parts have to perform. The weakest part of a tire is at the point where the side wall leaves the bead, and in order that the tires should give the maximum life it is necessary that they fit into the bead snugly.

The bead may be dented through running on a deflated tire or when passing over some obstacle. Passing over stone so that the bead receives a slanting blow is sufficient to cause the bead to become dented. This will unduly pinch the tire, with the result that the canvas at this point will be forced to undergo undue strain and in time give way.

Unless the tire fits the rim blowouts will not be at all unlikely. The following table shows the different dimensions of rims for various sizes of tires, and it would be well for the autoist if he has trouble with his tires to carefully measure the rims with a pair of calipers to ascertain if the dimensions are correct. It is false economy to try to fit a tire to a rim which was never intended to take it, because if the tire is too small the stretching that the tire undergoes spoils it, while on the other hand if the tire is too big for the rim it will not stay on properly. The dimensions in the table are in millimeters as it will be found, for people who are not used to working down to small fractions of an inch, that this form is simpler:

Tire Pressure.	90 lbs.	100 lbs.	120 lbs.	136 lbs.
E	51	62	67	77
D	8	9	11.5	12
M	12	15	16.5	16.5

The point E denotes the width of the rim at the lips, and it will be found that inside calipers are the best for making the measurement, or outside calipers may be turned, so to speak, inside out and used as inside calipers. The distance denoted by D may be best found by inserting a rule in the rim, and the same applies to M. One point that should be borne in mind is that although D may be correct as well as M, nevertheless it is necessary for E to be correct also, otherwise the tire will have a tendency to pull out of the rim.



Section through the rim of an automobile wheel indicating various measurements

THE THERMO-SYPHON SYSTEM—While it is common talk to the effect that the thermo-syphon system works by natural circulation, the fact remains that steam is generated at the hottest zone over the combustion chamber, and this steam, coming off of the surface in a slug, rushes away through the course of least resistance, and acts very much as the plunger of the pump. It has the potential force of the energy stored in it, and is perfectly capable of doing mechanical work in substantially the same way that the plunger of a pump drives water before it, or creates a depression into which water runs. In addition to the mechanical effect of the slugs of steam driven off during each power stroke, there is the natural difference in temperature between the water over the hot zones and that in the rest of the cooling system, and to some extent this difference is responsible for the circulation: this alone, however, would act sluggishly.

Ramifications of the Maxwell

Dealing Particularly with the "Special" Model

It is proposed to show in this article the latest type of the Maxwell line and the distinctive features of the models, also some of the processes of manufacture. A department is set aside to the testing of the various parts before being assembled in the chassis.

A NEW model has been added to the Maxwell line of cars manufactured by the Maxwell-Briscoe Motor Company, of Tarrytown, N. Y. It will be known as the Maxwell Special rated at 36 horsepower. In addition to this model the buyer's choice comprises the Maxwell Mercury, which is a roadster guaranteed to cover a mile a minute, rated at 30 horsepower; a 25-horsepower car known as the Maxwell Mascotte with either a touring or roadster body, ending up with the 16-horsepower runabout of the past season with certain refinements, now known as the Maxwell Messenger. The system of designating cars by name rather than by letters or numerals is a happy one, as it is more convenient to remember a car in this manner than by several meaningless hieroglyphics.

It is proposed in this article to deal more particularly with the Maxwell Special, and unless specific mention is made of any other model the description and details that follow will have reference to the Special. The motor is of the four-cylinder, four-cycle type, with the cylinders cast individually. The valves are placed on opposite sides of the motor as the cylinders have T-shaped heads. A general idea of the motor, together with the housing of the transmission and clutch units, can be seen by referring to Fig. 9, which shows the exhaust side of the motor, and Fig. 10, which shows the intake side, with the cover that encloses the timing gears, clutch and transmission removed. It will be seen in Fig. 9 that the flywheel is placed at the front extremity of the motor, and is cast from a special grade of iron, and is 19 inches in diameter. The face width is 2 1-4 inches, and in order to maintain a perfect balance both the sides and the face are ground, which operation is shown by referring to Fig. 18, from which it will be seen that the weight is carried at the periphery and the spokes form a fan to assist in inducing an air draft through the radiator. The bore of the Special model is 4 1-4 inches, and the stroke of the piston is 5 1-4 inches. The extreme length of the cylinders is 9 29-32 inches. The valves are of the mushroom type and the diameter of the valve seat opening is 1 3-4 inches, and the lift allowed to the intake valves is 5-16 of an inch, while the exhaust valve is given a lift of 11-32 of an inch.

A point of which the average owner of a car is ignorant is the proper timing of his motor. In the Maxwell Special the intake valve opens 15 degrees after top dead center, or 2.487 inches on the rim of the flywheel, and closes 40 degrees, or 6.632 inches on the rim of the flywheel after the lower dead center. The exhaust valve closes 10 degrees, or 1.658 inches on the rim of the flywheel, after the top dead center and opens 40 degrees, or 6.632 inches on the rim of the flywheel before lower dead center. From this it will be seen that there is a period between the closing of the exhaust valve and the opening of the intake when the cylinder is in a manner creating a vacuum, and it has been found by the manufacturers of this car that this method of timing tends to induce a stronger depression in the carbureter, thereby filling the cylinders with a proportionately larger amount of mixture properly atomized.

The crankshaft shown in Fig. 1 has five main bearings, which are plain babbitt, and the diameter of the journals is 1 3-4 inches. The length of the front bearing, the extension of which carries the flywheel, is 3 1-4 inches long. The intermediate bearings are 2 5-8 inches, and the rear bearing is 2 13-16 inches long. It will be seen that a gear is attached to the end of the crankshaft and this forms the master pinion for driving the trains of half-time gearing. The clutch assembly is attached to the extension arm piece on the end of the crankshaft and the primary shaft of the transmission, which is of the square type, on which the sliding gears are attached, being a continuation thereof, terminating in a step type of journal, and the master part of the universal joint that is placed outside of transmission housing. The piston, together with the connecting rod, cap, bolts and shims, are shown in Fig. 21. The piston is first turned and afterward ground from a special gray iron, the grinding operation being shown in Fig. 18. The operator, in this illustration, can

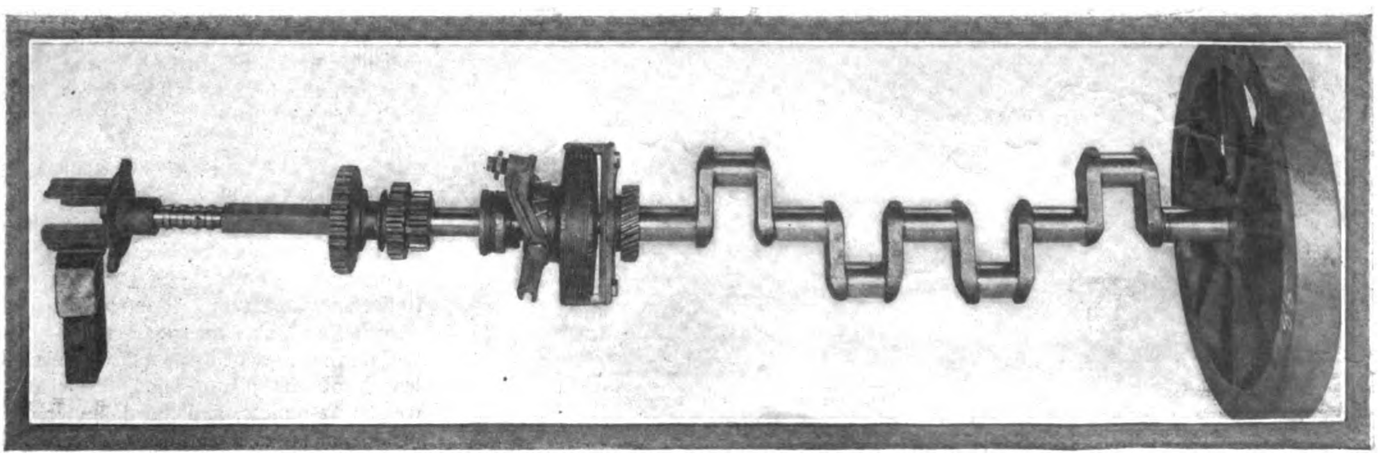


Fig. 1—Showing the assembly of the flywheel, crankshaft, clutch, primary shaft of the transmission, sliding gears and universal joint

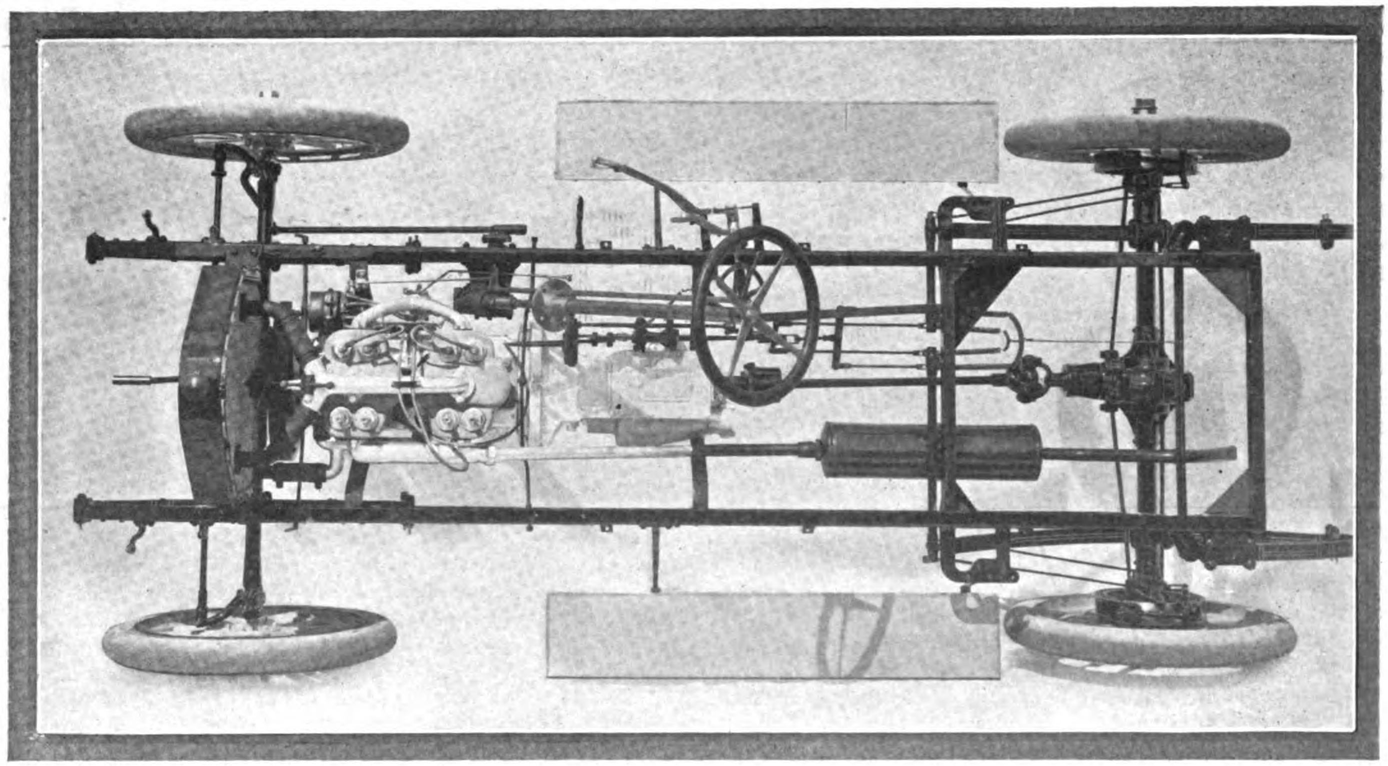

Fig. 2—Plan view of the Maxwell Mascotte chassis, showing the assembly of the motor with its three-point suspension and other details

be seen placing micrometer calipers on the piston to determine down to an infinitesimal small margin the necessary clearance for a good working fit. The cylinders are treated in a similar manner, only in this case a special cylinder grinding machine is used instead of the one illustrated in Fig. 17. Fig. 21 shows the piston P, which is fitted with four piston rings with diagonal slots. The ring R4 is placed near the base of the piston, and while retaining a goodly quantity of lubricant between it and the ring R3 serves, in a measure, to prevent an excess of oil escaping past it, which would thereby find its way into the cylinder spaces.

The lubrication system in this motor might be termed the semi-splash system. The actual lubrication of the reciprocating part is dependent upon splash. Beneath each connecting rod a trough T, as shown in Fig. 21, is screwed in position by the four arms A1, A2, A3 and A4, and the cap of the connecting rod is fitted with a knife-edge extension K seen in the same illustration, which churns the oil up at each revolution of the crankshaft.

Fig. 22 shows a sectional view of the base chamber with the two center connecting rods dipping into the scoops. Below the scoops the base chamber forms a reservoir for the oil that is poured in through the filler O, the correct level being ascertainable by opening the cock C1 while the oil is being poured in. Should the oil, however, reach above the level of this drain-cock, the motor will not of necessity become over-lubricated unless the oscillations of an uneven road were to cause the oil to be thrown up in larger quantities than was provided for by the makers. Fig. 9 shows the exterior of the base chamber and a gear-driven pump P driven by helical gearing from the exhaust camshaft. The oil is taken along the pipe P1 in Fig. 22 into the pump and thence driven under pressure to a sight feed situated on the dashboard. In some makes of cars this feed is so small that, owing to the dirty state of the oil that is continually being passed through the motor, the sight feed becomes black and it is impossible to see whether the oil is circulating or not. This fault cannot be laid at the door of the Maxwell. Fig. 15 shows the size of the sight feed at O. After the oil has passed through the feed it returns along a single pipe which passes the whole length of the base chamber, and maintains a steady stream to each trough below the crank throws. The big ends of the connecting rod are lubricated by means of the oil that finds its way down the slot S. there being a hole drilled at the base of this into the bearing. The lower half of the bearing is also drilled so that each half of the journal receives its full quota of lubricant. The bearings are filled with an anti-friction metal and five shims of varying thicknesses are provided for each connecting rod so that an infinitesimally small amount of wear can be taken up as soon as it becomes apparent. Refinements of this description make the possessor of a car feel more confident in its maintenance. The length of the piston is 4 5-8 inches and weighs 61 ounces, and the diameter of the piston pin is seven-eights of an inch. The camshafts of the motor are driven by helical-cut gears driven from the master wheel,

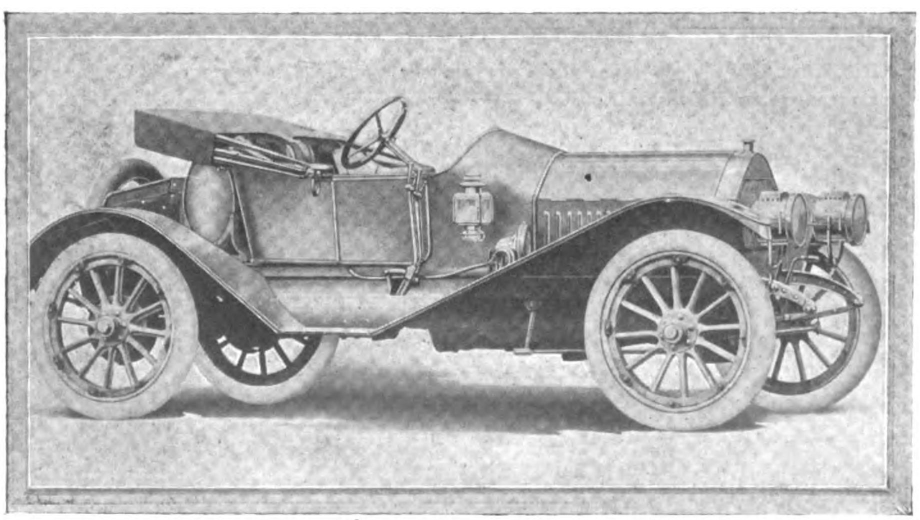

Fig. 3—General appearance of the Maxwell Mercury Roadster, with vestibule body

which is attached to the crankshaft. The diameter of the camshaft is three-fourths of an inch and is supported by five plain babbitt bearings which are driven into the aluminum housing, and afterward reamed to size. The cams are attached to the camshaft by means of taper pins. Fig. 14 shows the operation as carried out in Tarrytown of cutting the gears for the halftime wheels. Both sides of the motor, as can be seen from Figs. 9 and 10, are fitted with inspection doors which make it possible to readily inspect the working parts of the motor without taking same asunder. The crankshaft is held in position at its front and rear extremities by covers formed integral with sliding blocks that complete the housing fore and aft of the base chamber. This style of fitting is carried out in the transmission, which makes it possible after the cylinders have been removed to lift out the whole unit as shown in Fig. 1.

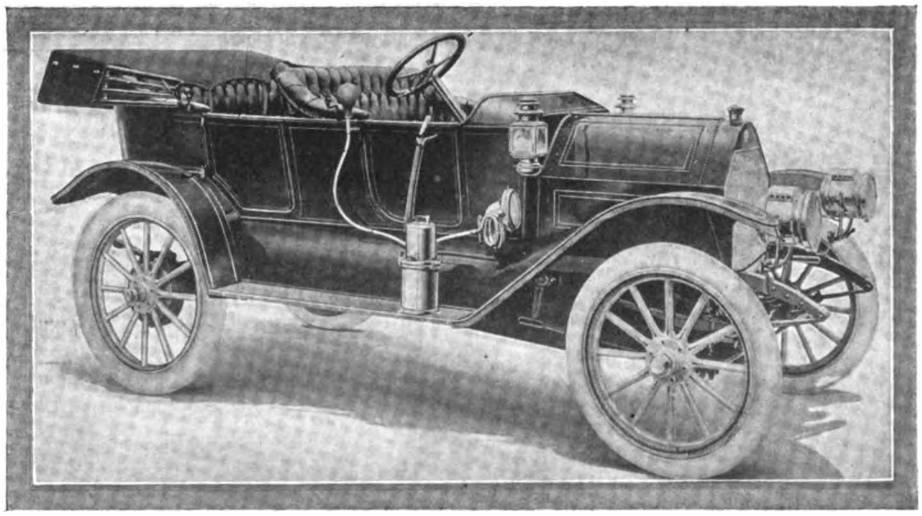

Fig. 4—Maxwell Mascotte 25-horsepower touring car with flush-sided fore-door vestibule body

In Fig. 12 is shown the front end of the motor and the method in which the Splitdorf magneto is held in position. The intake camshaft is extended through the base chamber and attached to it is a gear wheel which meshes with the gear attached to the armature shaft of the magneto, and being geared two to one, the magneto runs at engine speed. A cover is provided that fits over the gears and in order to eliminate noise the magneto gear wheel is made of compressed fiber faced on both sides with a sheet of steel to prevent any expansion under load. The extension of the crankshaft carrying the flywheel also forms the resting place for a pulley wheel which drives the fan belt. The ignition is obtained by means of a magneto in connection with a non-vibrating coil and batteries for starting.

The location of the coil is well shown in Fig. 15, where it will be seen that a switch is provided upon the coil controlling both battery and magneto ignition. Fig. 9 shows the method adopted on this model of casting the cylinders and introducing the water to the lowest point of circulation at W1, W2, W3 and W4. The water is circulated on the thermo-syphon principle, the pipe conducting the water back to the radiator being of large diameter and bifurcated at the point where it leaves the forward cylinder, entering the radiator at two points a little over half way up, instead of at the top as is usual. A fan driven by a circular rawhide belt provided with a ready means of taking up slackness maintains a good suction of air through the radiator at all speeds of the motor, and as it runs upon ball bearings little power is taken up in its operation.

The carbureter, of the float feed constant level type, is located on the right-hand side of the motor and placed sufficiently high to permit of easy adjustment if it should be found necessary at any time.

The clutch employed on this model is of the multiple-disc type, both sets of discs being made of steel with ground faces. The component parts of the clutch may be seen by referring to Fig. 6. The part A is attached to the crankshaft, and bolted thereto by means of studs S and S1 is a crosshead C. This has two protrusions upon which the part is resting engaging the jaws J and J1. The disc D with a castellated shaft

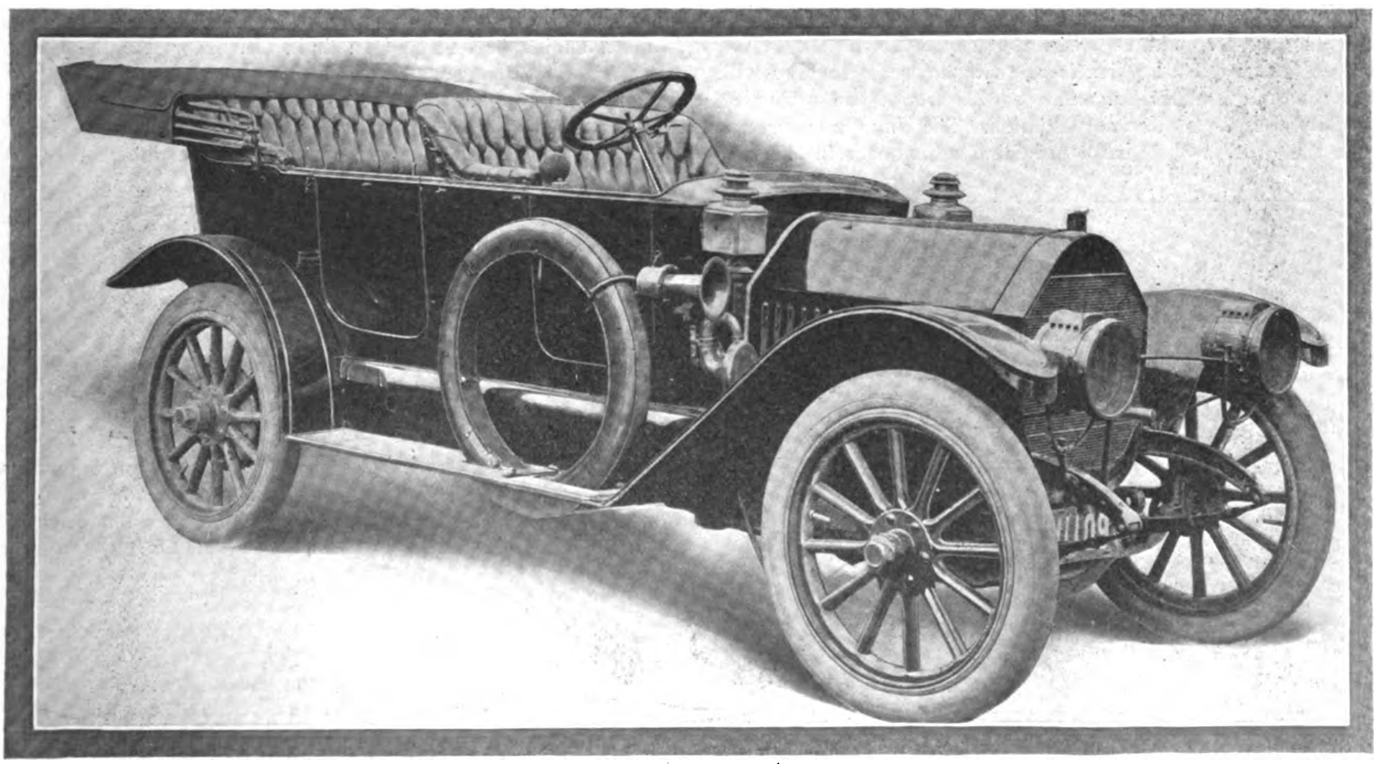

Fig. 5—Showing the Maxwell Special 36-horsepower fore-door touring car with full equipment

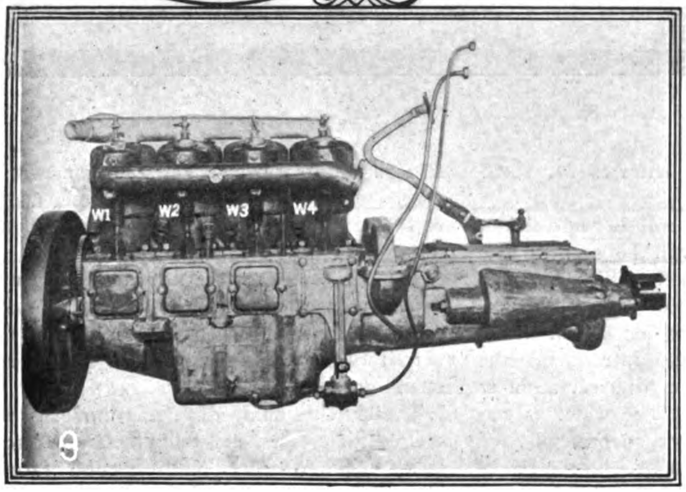
Fig. 8—Various parts forming the general assembly of the steering mechanism



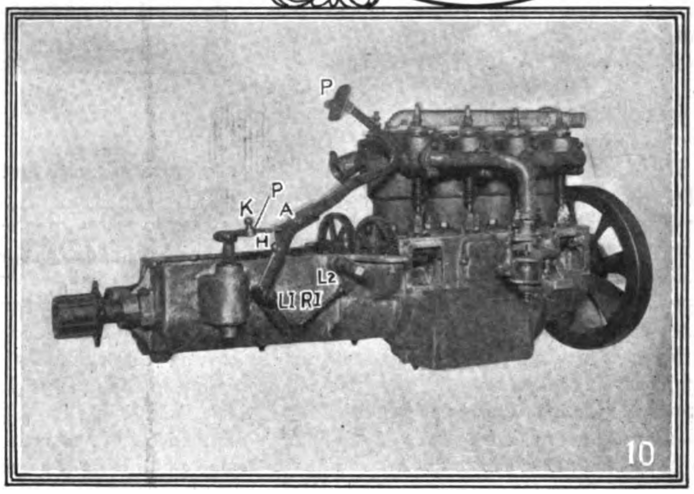


Fig. 9—Exhaust side of the Maxwell Special motor, showing the method of obtaining a three-point suspension and the lubricating pump

Fig. 10—Intake side of the Maxwell Special motor, showing the adjustable valve push rods, and half-time gearing and pedal control

S2 passes over the journal J2 and alternate discs of the type as shown at D1, which have six slots cut in them to correspond with the keys on the shaft S2, form the driving members. The ribs R and R1 engage with the slots S3 and S4 of the disc D2 which alternate with the discs of the type shown at D1. The plate P1, the inside of which is cut with keyways, engages with the keys on the shaft S2, and the pressure of the spring S3 maintains the plates in contact relation. The ring R2 is screwed on to the threads T, thereby providing adjustment in the case of wear. A collar C1, which is at the same time a ball bearing, receives the engagement fork and compensates for the thrust when the clutch is disengaged. The parts P and P1 are attached to the ends R and R1 by the set screws, thus preventing the plates from expanding beyond a given limit. In order that the plates may properly disengage the driven plates of the D2-type they are cut at four points and the edges turned outward as a substitute for disengagement springs. The clutch is operated by a pedal P1, shown in Fig. 15, which, at the same time, serves to

apply the emergency brake when pushed right home. The general assembly of the pedal and interlocking mechanism is shown in Fig. 10. When the pedal P is depressed the lever arm L1 is drawn backward carrying with it the rod R1 and the lever L2. This lever is attached to a cross-shaft inside the clutch housing to which in turn is attached a cam. This cam forces the disengagement fork backward and an adjusting screw as provided serves to regulate the amount of disengagement. The hole H receives the rod that operates the emergency brake and by depressing the pedal farther than is necessary to disengage the clutch the brake is brought into action. The knob K in Fig. 10 is connected to the change-speed lever, and a device is provided which makes it impossible to change speed unless the clutch is withdrawn, or to engage the clutch unless the gear lever is either in the neutral or one of the gear positions. This consists of a plate P which rotates with the knob K and fitted with slots and it is necessary for the arm A of the change-speed pedal to engage one of these slots otherwise the clutch is withheld. The

emergency brake, which is operated by a lever placed on the right of the driver, also disengages the clutch in the same way as indicated by the emergency brake pedal, a separate cam being employed. Ignition and throttle levers are provided below the steering wheel, working on ratchet sectors, and a pedal is also employed to control the gases. The general control can be seen by referring to Fig. 15. The transmission is shown as seen from above in Fig. 7. The lever which operates the train of sliding gears works in a push-through type of quadrant. The gear G1 when meshing with G2 gives the first speed. When the gears G3 and G4 are in mesh, as shown in the illustration, the second speed is in operation. The high gear is obtained when the dogs D1 are caused to mesh with the corresponding members in the interior of G3. G5 is attached to the extension of the clutch shaft and is in constant mesh with G6. The gear G5 has a bronze bush within which the extension of the shaft S1 runs. The power is transmitted from G5 to G6 and thence to the several gears situated on the shaft S2, and so back to the primary shaft S1 when the gears are caused to mesh by the shifting fork F1. The reverse is obtained by meshing the gear G1 with the gear wheel G7. In this case the power is transmitted from G5 to G6, thence to G8, which is in constant mesh with G7, and so back to G1.

The secondary shaft S2 is carried at its forward and rear extremity upon long roller bearings, and the primary shaft S1 on anti-friction white metal bearings. The slides S3 and S4 form the upper half of the bearings and are detachable by removing the nuts N1, N2, N3 and N4. The cover that encloses the transmission is made in one piece together with the part that encloses the timing gears and clutch housing, and is readily removable for the purpose of inspection. The power is transmitted from the transmission to the live rear axle by means of a propeller shaft fitted at the forward and rearward ends with universal joints, the rear universal joint being shown in Fig. 13. The live rear axle is of the full-floating type and this is shown in Fig. 13 with the half cover removed. The driving pinion together with its bearings is housed in the part of the casing marked C1, and the differential assembly comprising the crown wheel W1, differential cage D1 and the supporting bearings are held in position by the braces B1 and B2. When these are removed it is possible to lift the differential bodily from the housing should this be found necessary at any time, of course, after the jackshafts have been withdrawn. A tie rod T1 is placed beneath the axle with an adjustment at either extremity and serves as a strengthening member. Fig. 11 shows the assembly of the brakes, the jackshaft and the torque member, as well as the three-quarter elliptic springs, and the method of attachment of the latter. The torque tube T1 is attached at its rear extremity to an arm and at the forward extremity to a ball socket. B attached to the side member of the chassis. Rubber buffers are provided to prevent the chassis frame striking the springs, the forward ends of which are supported in a common bracket that is used at the same time as the supporting member for the brake levers. Both the brakes operate upon the common brakedrum, the outside diameter of which is 12 inches, and the face being 1 3-16 inches. The friction surface thus obtained is 82 1-2 square inches per brake. The operation of milling the four surfaces of the universal joint is shown in Fig. 16 in which four cutters rotate at the same time and plane the interior and exterior surfaces of the fork. The rear springs are 50 1-2 inches long and 2 inches wide, and as it can be seen by Fig. 11, are of the three-quarter-elliptic type. The front suspension of the chassis is taken care of by semi-elliptic springs of the same width as the rear, but 36 inches in length. The front axle is an I-beam drop-forging and the wheelbase of the car is 114 inches having a tread of 56 inches. The wheels are 34 x 4 inches and are fitted with quick detachable rims. The steering assembly is shown in Fig. 8. It is of the worm-and-sector type, the sector fitting into the recesses R and R1 of the casing C and the cover C1. The journals J and J1 run respectively in the bearings B and B1 which are turned from steel, case-hardened and ground to fit. The sector S engages with the worm W, which latter is held in position at its lower extremity in the bronze bushing B2, which fits into a recess of the casing C. The upper end of the worm-shaft is held in position by the threaded cover T which is provided with a bronze liner. The adjustment of the worm and sector is effected by tightening of the slotted head H of the part T. The drop arm of the steering D is attached to the square end S1 of the sector S, and a bolt which engages with a slot in one of the angles of the squares maintains the parts rigid.

The general appearance of the Maxwell "36" can be seen by referring to Fig. 5, in which it will be noticed that the shape of the radiator has been altered and is now made of the true honeycomb type. The front compartment of the fore-door body is provided with ventilators, thereby removing an objection that is sometimes made for this style of coach work, and in order to better carry the spare tire, a countersunk well is formed in the runningboard as shown in the illustration. Besides supporting the tire better, the reduction in height greatly improves the appearance of the car. It will be noticed that the side balances between the runningboard and the chassis frame entirely cover in such parts as spring shackles and brake levers, and give the car a very clear aspect. The Maxwell Mercury mile-a-minute roadster is shown in Fig. 3, with large capacity gasoline tank, waterproof baggage compartment and spare tire carried behind the bucket seats. The general appearance of the Maxwell Mascotte 25-horsepower touring car, having a 4 x 4-inch motor, is shown in Fig. 4, the chassis of which is shown in Fig. 2.

In order to ensure that the parts that are fitted in Maxwell cars have been thoroughly tested before being delivered to the chassis assembling department, a special force provided with the proper facilities makes a thorough test of the various assemblies in the first place. Fig. 21 shows the manner in which the lubricating oil pumps are attached by suitable means to an improvised camshaft. With the aid of the step pulleys it is possible to cause the pump to rotate at a speed equivalent to from 4 to 60 miles per hour. The oil is then forced to gauges which are placed on the testing board, as can be seen by referring to the illustration, and the flow thereby ascertained. It is not often that a leak in this type of pump occurs, but it may happen that the gears are either to tightly in mesh or not enough so, in which case all errors can be rectified before the car is handed over to the customer.

It is of vital necessity for any company who wishes to obtain the confidence of the buying public that it should make independent tests of all apparatus that it does not manufacture itself. A point that is sometimes overlooked by testers is that although a spark plug may fire perfectly under atmospheric conditions, nevertheless, when under the pressure of the compression in the cylinder, which, for example, may be 70 pounds, the plug would utterly fail. The method adopted in the Maxwell plant of testing all ignition apparatus that goes into the cars is shown in Fig. 19. The magneto is fitted to a base and rotated at varying speeds by means of a belt. The spark plugs are screwed into small chambers C1, C2, C3 and C4, provided with glass windows. Pressure is then introduced into these chambers, the amount being indicated by the dial D. A relief valve V placed in the air circuit regulates the amount of pressure in the small compartments and by turning this either to the right or left, in which case the pressure is varied, it is possible to ascertain if either the plug or the magneto which includes the step-up transformer coil are in working order.

In order that the compression of the motor in each of the four cylinders should be maintained uniform, it is necessary that the tension of the piston rings should be equal, for, unless this is so, a certain amount of compression will be liable to leak, thereby upsetting the carefully planned calculations of the designers. The method adopted can be seen by referring to Fig. 20. A bracket is provided in which the lower half of the piston ring is attached by means of a thumb-screw. The opposite side of the slot is then attached to a bracket having two arms, from which is suspended a hook which in turn carries a weight balance. The operator in this instance is seen placing an additional weight upon the balance, and a ready calculation of the weights imposed will give the tension of the ring.

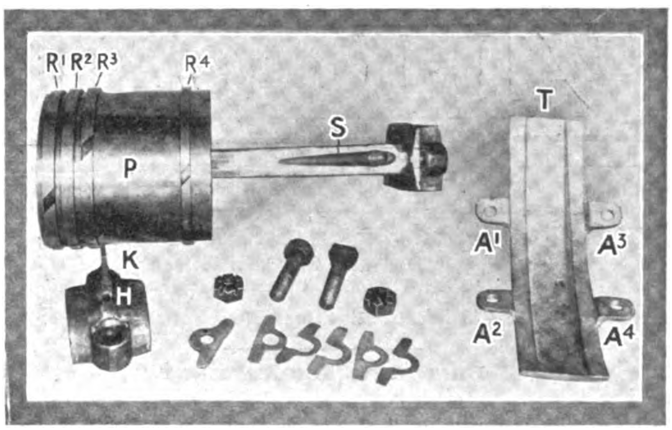

Fig. 23—Showing the piston, connecting rod, cap and shims and one of the troughs used in the lubricating system

A Muddy Weather Tip

STARTING a car on a muddy day is a most disagreeable undertaking, as the starting handle is usually besmeared with mud. This may in a measure be overcome by fitting a boot for the handle to rest in, but the leather soon becomes sodden with moisture and the consequences are almost as bad as if no protection at all were used.

Quite apart from the inconveniences that attend the starting there is another aspect that is more important. The mud that is thrown up by the front wheels bespatters the face of the radiator and quite a large proportion is sucked between the interstices thereby restricting the flow of air that has to pass in order to effectively cool the water. Some of the foreign matter finds its way into the motor compartment and if allowed to remain will cause rust to set in, the disadvantages of such a state of things being obvious.

In order to overcome these inconveniences, a pair of leather flaps can be made so that they can be attached by strips extending sufficiently low to protect the starting handle and carried up slightly above the frame to protect the radiator. Being detachable and perhaps detracting from the general appearance of the car, they may be carried under the seat ready in case of need.

Calendar of Coming Events

Handy List of Future Competitive and Show Fixtures

Shows

Jan. 1-5, 1912......New York City, Grand Central Palace, Annual Show, Automobile Manufacturers' Association of America.
Jan. 6-13...........New York City, Madison Square Garden, Twelfth Annual Show, Pleasure Car Division, Automobile Board oi Trade.
Jan. 10-17..........New York City. Madison Square Garden, Annual Show, Motor and Accessories Manufacturers.
Jan. 10-17..........New York City, Grand Central Palace, Twelfth Annual Show, National Association of Automobile Manufacturers.
Jan. 15-20..........New York City, Madison Square Garden, Twelfth Annual Show, Commercial Division, Automobile Board of Trade.
Jan. 27-Feb. 10....Chicago Coliseum, Eleventh Annual Automobile Show under the auspices of the National Association of Automobile Manufacturers.
March 2-9.........Boston, Mass., Tenth Annual Show, Boston Automobile Dealers' Association, Inc.

Race Meets, Runs, Hill-Climbs, Etc.

Sept. 6-9..........Buffalo, N. Y., Grade I, Reliability Run, Automobile Club of Buffalo.
Sept. 8-9..........Hamline, Minn., Track Races, Minnesota State Automobile Association.
Sept. 9............Augusta, Me., Hill Climb.
Sept. 9............Cincinnati, O., Road Race, Fern Bank Dam Association.
Sept. 9............Hartford, Conn., Track Races, Connecticut Fair Association.
Sept. 9............Port Jefferson, L. I., Hill Climb, Port Jefferson Automobile Club.
Sept. 9............Riverhead, L. I., Road Race, Port Jefferson Automobile Club.
Sept. 12-15........Omaha, Neb., Third Annual Endurance Run, Omaha Motor Club.
Sept. 13...........Grand Rapids, Mich., Track Races, Michigan State Aute Association.
Sept. 15...........Knoxville, Tenn., Track Races, Appalachian Exposition.
Sept. 16...........Syracuse, N. Y., Track Races, Automobile Club and Dealers.
Sept. 16-17........Kansas City, Mo., Track Meet.
Sept. 18-20........Chicago, Ill., Commercial Reliability Run, Chicago Motor Club.
Sept. 19...........Burlington, Vt., Reliability Run, Merchants' Protective Association.
Sept. 23...........Philadelphia (Point Breeze), Track Races, Philadelphia Automobile Trade Association.
Sept. 23-25........Detroit, Mich., Track Races, Michigan State Agricultural Society.
Sept. 25-30........Atlantic City, N. J., Convention and Exhibition of the Carriage Builders' National Association.
Sept. ....Denver, Col., Track Races, Denver Motor Club.
Sept. ....Steubenville, O., Hill Climb, Automobile Club of Jefferson County.
Oct. 6-13..........Chicago, Ill., Thousand-Mile Reliability Run, Chicago Motor Club.
Oct. 7.............Danbury, Conn., Track Races, Danbury Agricultural Society.
Oct. 7.............Philadelphia, Fairmount Park Road Races, Quaker City Motor Club.
Oct. 7.............Springfield, Ill., Track Races, Springfield Automobile Club.
Oct. 13-14.........Atlanta, Ga., Track Races.
Oct. 14............Santa Monica, Cal., Road Races.
Oct. 14 (to 25)....New York City, Start of the Annual Glidden Tour, en route for Jacksonville, Fla.
Oct. 16-18.........Harrisburg, Pa., Reliability Run, Motor Club of Harrisburg.
Nov. 1.............Waco, Tex., Track Races, Waco Auto Club.
Nov. 2-4...........Philadelphia, Reliability Run, Quaker City Motor Club.
Nov. 4-6...........Los Angeles,-Phoenix Road Race, Maricopa Auto Club.
Nov. 9.............Phoenix, Ariz., Track Races, Maricopa Automobile Club.
Nov. 9, 10, 12.... San Antonio, Tex., Track Races, San Antonio Auto Club.
Nov. 27............Savannah, Ga., Vanderbilt Cup Race, Savannah Automobile Club.
Nov. 30............Los Angeles, Cal., Track Races, Motordrome.
Nov. 30............Savannah, Ga., Grand Prize Race, Savannah Automobile Club.
Nov. ....Columbia, S. C., Track Races, Automobile Club of Columbia.
Dec. 25-26.........Los Angeles, Cal., Track Races, Motordrome.

Foreign Fixtures

Sept. 9............Bologna, Italy, Grand Prix of Italy.
Sept. 10-20........Hungarian Small-Car Trials.
Sept. 16...........Russian Touring Car Competition, St. Petersburg to Sebastopol.
Sept. 17...........Semmering, Austria, Hill Climb.
Sept. 17...........Start of the Annual Trials Under Auspices of *l'Auto*, France.

GREATER ACCESSIBILITY NEEDED

ACCESSIBILITY is more needed on many cars than any other feature at the present time. Accessibility is needed because it reduces cost of car operation. The lack of accessibility means expense. That car does not exist which will not give trouble sooner or later; it may have a clean sheet for a good many miles, but the day will come when an exhaust valve spring will weaken and a new spring have to be used; then comes the test of accessibility. It is a difficult task to change a valve spring on some motors. Often on the exhaust side the manifold is carried so low down that it is difficult to get an ordinary valve-removing tool into position without danger of getting the hands burned by rubbing against the hot manifold. Added to this complication is that of having the magneto mounted so that it is directly in the way of reaching one, or perhaps two, of the springs, and here is where more time and patience are lost.

The foregoing is but an introduction to the opening chapter of what might develop into a resumé on inaccessibility in motor cars. Go to the opposite end of the car and try to adjust the emergency or foot brakes on not a few machines. In some it is an impossibility to adjust them without getting on your back on the ground, with your head perhaps in advance of the axle. When in this position it is further necessary to work your entire arm up through a labyrinth of rods, etc., to some out-of-the-way wingnut or perhaps an ordinary nut with lock nut. These have to be turned by a special wrench; it would be bad enough if they could be worked by hand, but demanding the use of a special wrench in such a restricted quarter adds to the misery. When the thought-to-be-right adjustment has been made the driver, owner or passenger, worms himself out from under the car and tries his brakes only to find that they have been over-adjusted or not adjusted quite enough. He repeats his laborious performance once again and, if good luck is not on his side, he may have to perform the task a third time. It takes a lot of patience for such gymnastics; it takes a lot of clothes also, and if the owner has put on a holiday suit it is ready for the cleaners, even although he has made use of a long duster in his work.

The majority of motors need to have the carbureter primed occasionally before starting. There are a score of cars at present on the market in which you run a big chance of getting three or four grease spots on the coat sleeve every time you reach in to press on the priming rod. This is expense to the owner. He may not charge it up to the operating expenses of the car for the year, but he should. It is just as much an expense as buying a new tire is; just as much an expense as having the brass work cleaned; just as much an expense as having the body polished from time to time, and just as much an expense as having the carbon removed from the cylinders. Car owners should be honest with themselves and keep the expense account correctly.

Every car owner should remember that inaccessibility is costly and particularly so when his car goes into the repair shop to have some part repaired or replaced. Every other part of the car that has to be removed before the broken part can be reached is adding to the cost of the repair. But this is only half of the story, as these inaccessible parts have to be put back in place again and the owner should bear in mind that he pays his 75 cents an hour for his inaccessibility. This is a part of the cost of operation. Not a few owners have wondered at the repairman's figures showing a certain repair on one make of car at a certain figure and the same repair on another car at nearly double the price. Inaccessibility is the answer. In buying a car the buyer should look to the costs of inaccessibility. He should look into the accessibility of the carbureter and its adjustments, to the brake adjustments, to the crankcase oil drains, to the clutch lubrication, to the lubrication of the universal joints, to the valve springs, to the fan adjustment, to the magneto, the water pump, the ignition wiring, the grease cups on the running gear in hidden places, as well as to a dozen or more details that will come up in the ordinary running of the car.

It would be a blessing to the industry if there were a reliability run every year in which the designing engineers were the drivers and mechanics. It would show to them the error of their ways in hundreds of cases. The points in question are often not engineering problems at all—the engineering design of the major part has been correctly carried out—it is the positioning of some appurtenance that gives the trouble. A carbureter may be of the best design obtainable, but if it is mounted with the needle valve or throttle adjustment between it and the motor crankcase it is entirely wrong. Cases of this kind are on record to-day; some makers who had such conditions a year ago have since altered them.

As a solution of the problem, or, better still, as a method of bringing accessibility more to the front, THE AUTOMOBILE suggests an accessibility contest for cars.

Instead of running the cars on the roads they are simply parked and the trial consists of removing parts from the cars and replacing them. Such a contest offers an unlimited field.

A few of its possibilities are: The time required to adjust each set of brakes; time needed to jack up a front or rear wheel; time to remove a carbureter; time to drain off water from a carbureter; time needed in changing a spark plug; time needed in draining the dirty oil from the motor crankcase and refilling; time needed to empty the gasoline tank and refill; time needed to adjust the clutch spring tension; time required to turn up all of the grease cups on the car; time that is taken to change a valve spring; time needed to put on a new fan belt; time required to adjust the lower bearing of a connecting rod; time to take off and replace the radiator; time for removing and replacing the magneto; removal and replacement of the water pump; putting on a new ignition terminal, etc., etc. The outcome of such a test would be most valuable, it would be an education to the car builders, and it would be a means of reducing cost of car operation to an amazing extent.

Garden Spaces Drawn

THE first official act of the Automobile Board of Trade in connection with the 1912 show at Madison Square Garden took place at 4 o'clock yesterday at headquarters, it being the drawing for positions at the show. In all 58 manufacturers drew for positions. The order of drawing was determined by the total value of cars manufactured by the different makers for the fiscal year up to June 30. This output was determined from the figures of the recent A. L. A. M. organization and by sworn statements from the different makers for their product from January 1 to June 30. First choice fell to the Buick Motor Company, who selected position 14 on the main floor. This is immediately in front of the entrance on the right. Second choice went to the Overland, who took position 15 on the center on the left. The order of the remainder in the oval in the center of the Garden floor was: E-M-F, Cadillac, Packard, Maxwell, Pierce, Chalmers, Hudson. The drawings beneath the gallery on the first floor in order were: Mitchell, Reo, Stoddard-Dayton, Oakland, White, Peerless, Locomobile, Oldsmobile, Stevens-Duryea, Winton, Pope-Hartford, Lozier and Franklin. Marmon could have had the last space on the main floor but preferred a position in the first balcony, this giving Stearns the last available place on the ground floor. The order of drawing for the first balcony was: Thomas, Everitt, Alco, Brush, Knox, National, Autocar, Premier, Elmore, Columbia, Jackson, Pullman, Haynes, Moline, Moon, Selden, Corbin, Lambert, American and Matheson. The drawing for Exhibition Hall on the ground floor was: Mercer, Case, Cartercar, Inter-State, Simplex, Amplex. The Speedwell had the preference of drawing before the Amplex, but preferred a position on the second balcony. The others in the second balcony in the order of drawing were: Garford, Ohio, Palmer & Singer, Marquette, Daimler, Atlas and McIntyre. These will occupy but one side of the balcony, the other side being given over to motorcycles. The usual space will be devoted to accessories. The show will be a duplication of last year, namely an exhibition for pleasure cars and accessories the first week and the second week devoted to commercial vehicles and accessories.

In the drawing nearly all of the companies were personally represented. Colonel George Pope was in charge assisted by M. L. Downs, secretary of the show.

List of General Motors Holdings

DETROIT, MICH., Sept. 4—An interesting document recently filed at Lansing gives what is believed to be the first authentic list of factories comprising the General Motors group. The list is as follows: Buick Motor Co., Cadillac Motor Co., Olds Motor Co., Elmore Manufacturing Co., Cartercar Co., Northway Motor and Manufacturing Co.; Marquette Motor Co., Randolph Motor Car Co., Rapid Motor Vehicle Co., Reliance Motor Truck Co., Welch Co. of Detroit; Welch Motor Car Co., Champion Ignition Co., Jackson-Church-Wilcox Co.; Michigan Auto Parts Co.; Oak Park Power Co., McLaughlin Motor Car Co., Ltd., and the Weston-Mott Co.

Ask for Glidden Changes

BY far the most important feature that came up in conjunction with the meeting of the National Association of Automobile Manufacturers yesterday was a recommendation from this organization to the Manufacturers' Contest Association that a change be made in the 1911 contest rules of the A. A. A. governing reliability runs. The recommendation was to the effect that the rules be immediately changed so that a grade 4 reliability contest can be held without the entrants being registered stock cars. This recommendation was made at the request of President Hooper, Counsel Terry, and Chairman Butler, of the American Automobile Association, and was made so that the present Glidden Tour can be competed for by unregistered cars. The recommendation will be considered by the Manufacturers' Contest Association at its meeting to-morrow. The voting members of the N. A. A. M. were generally favorable to the change. If the change is made it will allow many private owners to enter the tour with cars which are not registered. This change if made will only affect grade 4 contests, which penalizes for lateness at controls only and does not take into consideration penalties for work done on the road or final technical examinations.

Another important matter was the receiving a recommendation from a special committee of the Manufacturers' Contest Association, headed by Howard Coffin and Howard Marmon, on the question of the future of contests. The M. C. A. Committee brought up the matter of the national organization financing the contest board, the contest board being merely a body for the sanctioning of contests. The matter was immediately referred to the contest committee of the N. A. A. M., which committee will report the matter at the October meeting.

Philadelphia representatives presented to the N. A. A. M. the outline of plans for the organization of an insurance company solely for the control of automobile insurance, which would cover every form of accident, fire, theft, etc. The proposed organization of such a company is the outcome of the dissatisfaction in settling present motor car insurance claims. No definite action was taken in the matter. The majority of the stock would be held by car and accessory manufacturers. One feature of the policies would be that cars damaged by accident or fire would be repaired at the agency or factory of said car.

Annual Round-Up of Studebaker Dealers

DETROIT, Sept. 4—The present series of excursions being conducted by the Studebaker Corporation's E-M-F Company factories have taken a greater scope in introducing maker and dealer than anything of its kind. During the past week the Studebaker dealers from the Central and Western South have been present for two days each, as guests of General Manager Flanders. They will be succeeded by other delegations this week, as follows:

Sept. 5, Philadelphia and Washington; Sept. 6, Chicago, Ill.; Sept. 11, Dallas and Oklahoma; Sept. 14, Kansas City; Sept. 18, Indianapolis; Sept. 21, Minneapolis; Sept. 25, Fargo; Sept. 29, Des Moines and Sioux Falls.

Fast Time at Old Orchard

OLD ORCHARD, ME., Sept. 5—World's records were established at old Orchard Beach this afternoon. Unless there is some dispute over the length of the course—and there cannot very well be, for the A. A. A. has a certificate that it was of proper length—new marks have been set up for 25 miles and 50 miles.

In the 25-mile race (ten laps for the necessary distance), Louis Disbrow, in his special Pope-Hartford, nosed out Jack Rutherford in his National, in the last 500 feet of the route, and won in the remarkable time of 15:25—thought to be the record for the distance. The last event of the day, a race of 50 miles (20 laps of the course), was won by Rutherford, in his National, in 30.06 1-5, which, if correct, beats the old record by more than eight minutes.

The famous racers who have been at the three days' meet declared that Old Orchard Beach offers the best race course in the world. W. T. Kincaid, chairman of the contest committee of the Old Orchard Automobile Association, announced that there would be more races next year, earlier in the season, for three prizes aggregating $3,000. Following is a summary of Tuesday's events:

Mile Exhibition Against Time

Pos. Car.	Driver	Time
Stanley	L. F. N. Baldwin	:40

Five Mile Exhibition

Pope-Hartford	Louis Disbrow	3:58

Twenty-Five Mile Free-for-All

1. Pope-Hartford	Louis Disbrow	15:25
2. National	John M. Rutherford	15:26
3. Buick	G. C. Jessup	15:26⅕
4. Pope-Hartford	C. L. Bowler	15:36⅕
5. Interstate	Harry Endicott	15:39⅕

Match Race Ten Miles

1. Cole "30"	V. A. Neilson	7:56⅕
2. Interstate	H. J. Habich	7:56⅖

Fifty-Mile Race, Free-for-All

1. National	John M. Rutherford	30:06⅕
2. Pope-Hartford	Louis Disbrow	30:15⅘
3. Pope-Hartford	C. L. Bowler	30:40⅕
4. Interstate	Harry Endicott	
5. Jackson Flyer	Harry Cobe	

SUMMARY OF MONDAY'S RACES

Special Match Race, Five Miles

Car.	Driver.	Time.
1. Cole 30	Henry J. Habich	8.04
2. Chalmers-Detroit	N. A. Mitchell	8.56

Exhibition, Five Miles for Record

Pope-Hartford	Louis Disbrow	3.03

Free-for-All, One Mile Time Trials, $50

1. Stanley Steamer	L. F. N. Baldwin	42 seconds
2. National 40	John M. Rutherford	47 seconds
3. Buick 17	G. C. Jessop	54 seconds
4. Interstate	Harry Endicott	54 seconds
5. Pope-Hartford	C. L. Bowler	57 seconds

Class D, Free-for-All, Ten Miles, $100

1. National 40	John M. Rutherford	6.15
2. Pope-Hartford	Louis Disbrow	6.23

Exhibition Mile

Stanley Steamer	L. F. N. Baldwin	44 seconds

The First Day's Races

The first day's races were thoroughly successful and well contested. In the ten-mile contest there was a tough fight for honors. "Jack" Rutherford's National 40 finally won out. He got the lead at the start and maintained it throughout the route, though he was hard pressed by Louis Disbrow in the Pope-Hartford. The time of the winner was 6 minutes and 15 seconds.

Old Orchard beach, in being laid out for races, presented some difficulties at first. The whole beach is fully six miles long, but at the west end there are rocks and in the middle is the famous Old Orchard steel pier. Pillars from this structure were removed and a good course, two and a half miles in a straight line, was provided. Over this the five-mile races and the ten-mile races were run and the mile races were pulled off with a straightaway course for the distance covered. It was thought at first that some accidents might result because of the passage under the pier, but there was not even a semblance of a mishap. The fact that it was a holiday attracted fully 50,000 people on the beach to witness the races. On the beach, the crowd extended for the full length of the course. The Seventh Company of the National Guard, under command of Capt. Goodier, of Biddeford, did patrol duty, and aided in keeping the crowd back from the course.

It looked for a while, though, as if the races would be called off for the people got too near the course and simply would not move, but they were finally forced back to proper limits.

In the mile time trials Baldwin, in his Stanley steamer, covered the course in 42 seconds, which was the best time. Rutherford closely approached him with a 47-second mile.

The really best time of the day was made by Louis Disbrow, in his Pope-Hartford, in an exhibition five-mile event. He covered the distance in 3.03, which was at the rate of better than 98 miles an hour. Rutherford, in the ten-mile free-for-all, did the course at the rate of 96 miles an hour.

Seventeen Start in Buffalo Run

BOLIVAR, N. Y., Sept. 6—Seventeen contesting cars made the start from Buffalo this morning on the first stage of the second annual reliability tour given under the auspices of the Automobile Club of Buffalo. Heavy showers last night made the roads out of Buffalo unspeakably bad and as the result few cars escaped penalty. The morning's run was through very hilly country and extra water and gasoline were required by the majority of the cars during the morning.

The run is scheduled for four days, each day's run ending at the parking station established on the spacious lot on Main street, just south of the Pierce-Arrow establishment. The outer mark on to-day's run is to Bolivar, N. Y.; Thursday, Dansville, N. Y.; Friday, Warren, Pa.; and Saturday, North Java, N. Y.

The tour is being run under the management of the Contests and Runs Committee of the Automobile Club of Buffalo, composed of Orson E. Yeager, chairman; Arthur W. Kreinheder, E. C. Sutton, I. N. Stewart, J. A. Murphy, Augustus H. Knoll and W. E. Blair.

There were nineteen entries, as follows:

Number	Car.	Driver
8	Everitt	J. W. Gardham
27	Paige-Detroit	J. E. McFadden
26	Warren-Detroit	J. S. Mohrhardt
21	Ford	G. Morton Wolfe
14	Ford	M. B. Leahy F. L. Rockelman
12	Ohio	E. A. Glaney
5	Cole "30"	E. A. Green
6	Lion "40"	H. L. Blomstrom
11	Schacht	E. W. Werick C. H. Werick
24	Oakland	Harold Harwood
20	Krit	Howard A. Bauer
29	Hupmobile	C. A. Almendinger M. R. Birk
3	Flanders	B. W. Scott
4	Flanders	T. R. Bell
9	Flanders	G. M. Herron
1	Maxwell	Charles F. Monroe
z	Maxwell	E. G. Gager
10	Maxwell	Thomas Costello
28	Abbott-Detroit	Frank H. Denny

Good Racing at Salem

SALEM, N. J., Sept. 4—The happy combination of perfect weather conditions and a holiday, served to attract a throng of 5,000 enthusiastic spectators from Philadelphia and South Jersey towns to-day to witness the automobile races conducted under the auspices of the South Jersey Motor Club, at the organization's Labor Day matinee meet on the half-mile track here.

Although many of the races were not blessed with an overabundance of entries, interest was sustained throughout the afternoon and the crowd was well repaid by some clever and daring driving. All races were run off as originally carded with the exception of Event No. 3, which went by the board by reason of the failure of one of the cars entered to put in an appearance. In two other events the issue was settled without a struggle, two out of the three cars in one failing to finish, owing to mechanical trouble, and in the other, containing but two entries, one dropping out before the finish, the winners triumphing in hollow fashion.

The event that stirred up the most enthusiasm and which created the most excitement was the trial against time for five miles. The former record for a half-mile track in New Jersey was 6:45, established at the Mt. Holly track, Mr. Harvey Ringler piloting a Mercer car, clipped two and one-fifth seconds from the old mark, the watches catching him as 6:37 4-5 seconds. Ringler was also successful in the first event, a five-mile affair, his opponent, Bob Morton, driving a Kline Kar, being forced to drop out. Tire trouble seemed to pursue the Kline Kar throughout the afternoon, as for one cause or another it failed to finish in any of the events entered.

The Velie car maintained its fine work of Saturday last at Pottstown and won both of the races in which it was entered, J. David at the wheel. Vincent Padula, of Philadelphia, had an easy time capturing the second event, five miles, neither of his opponents, a Kline Kar and a Metz, being able to stick.

In the concluding race of the day, a handicap event, the Abbott-Detroit, with Vincent Padula at the wheel and the Mercer car, Harvey Ringler driving, the finish was so close that the result is in doubt, there being little to choose between the two cars.

A.A.A. to Boost Good Roads

New York, Sept. 6—At to-day's meeting of the Executive Board, American Automobile Association, the National Good Roads Board was authorized to arrange for a Federal Aid Good Roads Meeting to be held in Washington, D. C., in September. The matter will be entirely in charge of Chairman Diehl of the Good Roads Board.

The North Dakota State Automobile Association was admitted into membership with the A. A. A. It is made up of three clubs and 200 individual members. This makes a total of 40 State associations in the parent body with an aggregate membership of over 50,000. The Bannock County Club of Idaho, and the Greensborough and Winston-Salem Clubs were admitted.

The matter of the Glidden Tour was taken up. At present there are thirty-five entries in hand and it is expected that seventy-five will be received by the closing date. This tour is to be a good roads boosting proposition and the majority of the entrants are private citizens of the South. In order to make the run more popular it is understood the Manufacturers' Contest Association will recommend the abolition of the stock car technical examination in conjunction with this run. This is being done in order to allow many private owners of unregistered stock cars to enter the tour.

Seven Clean Scores in Lake Tahoe Run

San Francisco, Sept. 1—The hardest endurance run ever held in Northern California has just been completed. It was a four-day endurance test between this city and Lake Tahoe and return, a distance of 520 miles, a great deal of which is through the Sierra mountains, rising to a height of 7,000 feet. About two dozen cars took part in the run, but only fifteen of these were officially entered as contestants. Of these fifteen seven secured perfect scores, as follows: American "Fifty" driven by Stanley Gawne; Buick "26," driven by Claud McGee; Buick "30," driven by Fred E. Gross; Elmore "30," driven by Bruce W. Aurandt; Flanders "20," driven by Stanley Jonas; Franklin "18," driven by A. S. Chisholm (official pilot car); and Winton "Six," driven by Harry L. Owesney.

Preparing for Port Jefferson Climb

Sixteen events will make up the program of the Port Jefferson hill climb, which is scheduled for Saturday, September 9. De Palma's Fiat, which holds the present record of the course—20.48—will not be in evidence, although there will be no dearth of fast cars among the competitors. The work of resurfacing the hill and banking the elbow turn has been in progress for some time, and the prospects for cutting a liberal slice off the present figures are considered excellent.

Westcott Wins 200-Mile

COLUMBUS, OHIO, Sept. 3—A crowd variously estimated at between 25,000 and 28,000 attended the 200-mile automobile race held under the auspices of the Columbus Automobile Club at the Columbus Driving Park Sunday, September 3. The race was one of the most successful in the history of automobile racing in Ohio and several records on a dirt track were broken.

Lee Frayer in a Firestone-Columbus went one of the miles in 54 seconds flat, which is a record in a contest on a dirt track. The time of Harry Knight in a Westcott, who won the race handily, was 3:45.00 flat.

There were three cars which finished the 200 miles out of the eight starters. Jackson No. 2 car driven by Max Borst and entered by J. P. Adamson, the local Jackson dealer, finished in 4:15.00 flat, while Jackson No. 1 driven by John Borst, a brother of the other Jackson driver, finished just 1 minute later, the time being 4:16.00.

The starters in the race were: Jackson, driver John Borst, entered by J. P. Adamson; Jackson, driven by Max Borst, entered by J. P. Adamson; Cino, driver William Fritsch, entered by Haberer & Company; Ford, driver W. G. Lake, entered by Ohio Auto Sales Company; Marquette-Buick, driver Frank Lawwell, entered by Leyman Buick Company; Wescott, driver Harry Knight, entered by the Wescott Motor Car Company; Firestone-Columbus, driver Lee Frayer, entered by Lee Frayer; Cole, driver G. Morris and John Jenkins, entered by Cole Motor Car Company.

The race was a sweepstakes with the purse of $1,000 divided into three moneys, viz., first money, $500; second money, $300; third money, $200. In addition the winners of the first three places received valuable trophies in the shape of loving cups.

The start of the race was made at 1:40 p. m., with the cars going at an estimated speed of 30 miles per hour. The lead was at once taken by Leo Frayer in the Firestone-Columbus, who kept it until the eighty-sixth mile when the car skidded while making a curve and went through a fence. Frayer was pinned under the car and was taken out after some trouble. He was not seriously injured and is expected to be around in a few days. The car was put out of commission by the accident which cannot be accounted for by Frayer.

The Westcott car driven by Harry Knight then took the lead and held it until the end. The car was never in danger and was compelled to stop only twice during the 200-mile race. The first stop was made after the car had made 114 miles and was for gasoline and oil; another stop was made later for one tire.

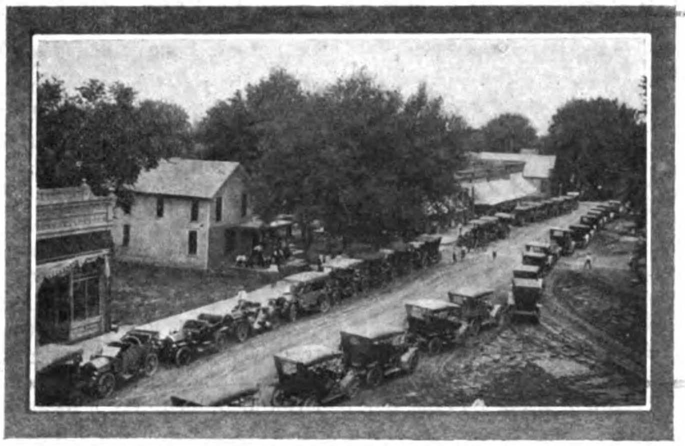
The Cino, driven by William Fritsch, only made 14 miles before it was compelled to leave the track because of magneto trouble. At the end of the thirty-first mile the Ford car, driven by W. G. Lake, was compelled to leave because of trouble with the water cooling system. The Cole entrant, driven by John Jenkins was compelled to leave at the end of the seventy-third mile because of engine trouble.

The accident that put the Firestone-Columbus car out of commission occurred at the end of the eighty-sixth mile on a bad turn in the track. The Marquette-Buick when in second place at the end of the 198th mile threw a tire and skidded into the inside fence. Frank Lawwell had given away to William Fritsch and Ben Lawwell was acting as mechanician. The latter was thrown high in the air but escaped serious injury and Fritsch was not scratched at all.

The winner of the race, Harry Knight, made the sixth mile of the distance in 58 seconds flat, which was his fastest mile.

24-Hour Race Announced for Brighton

During the running of the races at Brighton Beach on Monday, it was announced that application had been made to the Contest Board for a sanction for a 24-hour race to be held on that track between September 23 and 30. According to the announcement ten entries have been made.



More than two-score automobiles at one of the checking stations of the 100-mile Farmers' Sociability Run, at Kalona, Ia.

Farmer's "Sociability" Run

One of the greatest advantages of the auto on the farm is the sociability it affords, and the farmers are finding out that the automobile is fast doing away with the isolation and disadvantage of farm life. It is also encouraging the young folks to remain on the farm and putting a stop to the influx to cities.

In this connection, it is of interest to learn that forty-three farmers of Kalona, Iowa, have just completed what is said to be the first "Sociability" run ever held by farmer motorists. The tour covered 100 miles, starting at Kalona. The route led through Washington, Brighton to Richland and return. Not a single one experienced any mechanical trouble, which added greatly to the pleasure of the trip.

When it is remembered that these forty-three farmers all live in the same locality some idea is gained of the extent to which farmers are purchasers of automobiles. In this particular instance every car used in this run was the "Dreadnought" Moline.

Transcontinental Truck Arrives on Coast

San Francisco, Aug. 26—The first half of a most remarkable motor truck test was completed yesterday, when the Packard three-ton truck arrived here from New York. While this is not the first time that a motor truck has crossed the continent, it is the first instance that such a test has been made a day-to-day affair. The time of the Packard was forty-six and a half days from the time the big truck started from New York. The number of days that the Packard was actually on the road was forty-one, the other five and a half days being spent in the larger cities along the route.

The car is in charge of W. T. Fishleigh, body engineer of the Packard Motor Car Company. Accompanying him are E. L. Burnett and A. Haener, of the experimental department of the Packard Company.

Small Fields at Gearhart Beach

Tacoma, Wash., Sept. 2—Over 2,000 enthusiasts witnessed the races at Gearhart Beach on August 26. In the first race a Locomobile, driven by C. A. Barstow, won, covering the distance in 5 minutes 26 seconds. D. C. Reynolds, in a Pierce-Arrow, was second. The only other entry failed to finish. Carl R. Gray, president of the Hill lines in Oregon, presented a cup to the winner.

Robert Bearce, driving a Marion, won the second race in 5 minutes and 48 seconds. George Crab, in a Warren-Detroit, was second, and F. W. Perkins, driving an Overland, third. The race was for the Astoria Centennial Cup.

The third race was a handicap event and was captured by D. C. Reynolds in his Pierce-Arrow in 5 minutes and 30 seconds. C. A. Barstow, in a Locomobile, was second and Robert Bearce, driving a Marion, third. The Gearhart Hotel presented the winner with a cup.

The number of entries in the three races scheduled were not as many as the committee had anticipated.

Velie Stars at Pottstown

Pottstown, Pa., Sept. 2—The annual fair of the Montgomery County Fair Association was brought to a successful termination to-day by an afternoon of automobile racing conducted by the South Jersey Motor Club, the meet attracting more than 5,000 persons.

Interest centered in the attempt to lower the existing record for the mile circular track of 1 minute 2 1-5 seconds, hung up by the Mercer car last year, Harvey Ringler driving. William Mullin turned the track, clipping 1 1-5 seconds from the mark, negotiating the circuit in 1.01.

The carded events were five and ten-mile races in which Philadelphia pilots shone. Notwithstanding the fact that rain had continuously fallen for the preceding week or more and the sun had not put in an appearance until Friday, the track was in fine shape and the average time of the winners good. The fastest time made during the day was in event No. 6, won by the Velie car in 5.26 1-5 for the five miles, while the slowest was in th esecond event, 11.57 for the ten miles being the time taken by the Mercer car driven by Ringler.

Practically the same cars and drivers will take part in the races at Salem, N. J., on Labor Day. Summaries:

Ten miles, 161 to 230 cubic inches

Position.	Car.	Driver.	Time.

Sued for Appropriating Gasoline

Akron, Ohio, Sept. 4—Automobilists of Ohio and Michigan who have had occasion to ship their cars by boat either from Cleveland to Detroit or vice versa are up in arms over what they declare to be unfair treatment they have been receiving from the Detroit & Cleveland Navigation Company. When autos are run aboard D. & C. steamers at either end of the line the gasoline is of course drained from their tanks, in compliance with a marine fire insurance regulation. Arriving at the other end of the line an arbitrary rule is enforced, by which the boat company replaces only three gallons at the Cleveland end or five gallons at Detroit. Sometimes as much as twenty-five gallons are taken from tanks at the beginning of the run, and autoists have naturally felt that they had room for complaint, but their objections have thus far brought no revision of the rule. B. P. Foster, a Cleveland manufacturer and member of the Cleveland Automobile Club, who claims that on several occasions he was relieved of much more gasoline than was returned to him, has authorized his attorneys to begin suit against the D. & C. Company for the difference between the gasoline taken and the gasoline returned, or its equivalent in money. It has been estimated that the company has already benefited to the extent of thousands of gallons of gasoline by its rule.

Big Month for Winnipeg Motorists

WINNIPEG, MAN., Sept. 2—The automobile racing enthusiasts of Western Canada will have their speed hunger appeased on Saturday, September 16, when the annual Fall race meeting of the Winnipeg Automobile Club will be held on the mile track at Kirkfield Park.

In addition to the track races the endurance run to determine next year's holder of the Oldsmobile trophy will be held September 29-30. This contest is held over a central Manitoba course of 455 miles, which includes roads of every variety. Some forty starters are expected to compete.

The race card for the Kirkfield Park meet includes the following events:

Ten-mile race, for stock cars up to 160 inches piston displacement.
Ten-mile race, for stock cars from 161 to 230 cubic inches displacement.
Ten-mile race, for cars from 231 to 300 inches displacement.
Ten-mile race, for stock cars, 301 inches displacement and over.
One-mile open attempt for record.
Five-mile open race for stripped cars.
Dunlop trophy race, 25 miles. Open to any car or driver resident in the province.
Ten-mile open race for stripped cars.

Records Stand at Scranton

SCRANTON, PA., Sept. 5—Five efforts to break the record of 1.08 for a mile on a half-mile track failed at the Minooka Driving Park yesterday, Ralph De Palma making the trial twice, and R. A. Ammerman, Eugene Cusick, and Willie Haupt each once.

De Palma made the best time in his giant Simplex, a mark of 1.11 being credited to him. Two accidents marked the afternoon's sport. Eugene Cusick, of Scranton, in his Buick, driving in the five-mile, non-stock, class "C" free-for-all against De Palma and Haupt, had a narrow escape from death when he collided with the fence at the upper turn. A fence rail pierced the radiator.

Harry Kaufman, in a Buick, in the first event, two miles, non-stock, Class "C," likewise ran into the fence.

A crowd of 5,000 witnessed the races, which were under the auspices of the Scranton Racing Association. Summaries:

Pos.	Car.	Driver.	Time.
		Event No. 1—Two Miles

Record Crowd at Amarillo

AMARILLO, TEX., Sept. 5—The two-day race meet came to a close this afternoon in a highly sensational manner, when Carl Reeves, of Midland, Texas, driving a National "40" wrecked his car while going at a rate somewhat more than 70 miles an hour, caused by striking a soft earth roll at the inner line of the track. The machine was torn almost part from part, but one wheel retaining its spokes. The driver was thrown entirely across the track, sustaining a scratched elbow and bruised hip.

The first race of the afternoon was thirty miles, won by Staver-Chicago, driven by Nikrent, in 28 minutes and 27 seconds; second, Staver-Chicago, driven by Monckmeier, 28 minutes, 43 seconds; third, E-M-F, driven by Johnson, 30 minutes and 36 seconds; fourth, Cadillac, driven by Mullins, 30 minutes 56 seconds.

The second race, sixteen miles, was won by the E-M-F, driven by Johnson; time, 15 minutes and 55 seconds.

The 100-mile race was won by the National "40," driven by Wilcox; time, 96 minutes 56 seconds; second, Staver-Chicago, driven by Monckmeier, 103 minutes 15 seconds.

The 50-mile event went to the National "40," driven by Wilcox; time 46 minutes 59 seconds; second, Marmon, driven by Johnson. It was in this race that Reeves so narrowly escaped death.

On the first day the first event of twenty miles was won by the E-M-F 30, driven by Reeves, in 20 minutes 15 seconds, the Marion, driven by Day, finished second, and the Buick, driven by Tripplet, third.

The second race, thirty miles, was won by Staver-Chicago, driven by Monckmeier, in 29 minutes and 6 seconds, with Staver-Chicago second and E-M-F, driven by Reeves, third.

The fourth race, at fifty miles, was won by a National 40, driven by Reeves, in 44 minutes and 37 seconds, with National 40, H. E. Wilcox, second.

Setting Dates for Show Banquets

Dates for the big show banquets are being made and already it has been announced that the annual dinner of the Motor and Accessory Manufacturers will be held on the evening of Thursday, January 11, at the Waldorf-Astoria. A big attendance is already assured.

Tentative plans are also in process of formation with regard to holding a big combined banquet of the exhibitors and officers of the Automobile Board of Trade show at the Garden and of the National Association of Automobile Manufacturers show at the Palace. The function will probably be staged at one of the big uptown hotels and the date will probably be Tuesday, January 9.

New Entry to Gasoline Field

Hupp Corporation to Build Cars of That Type

A runabout type of automobile is now being manufactured by this concern, which has been known formerly by its activity in the electric field. through its production of the Hupp-Yeats. Other types of body will be added to the line as the business develops, and the cars produced will be known as the R. C. H., after the initials of the president of the corporation, R. C. Hupp.

THE announcement made by the Hupp corporation, of Detroit, Mich., during the first annual convention of this concern, brings to light the interesting fact that a new gasoline car known as the R. C. H. is about to find its way on the market. Heretofore this corporation has been known by the production of the Hupp-Yeats electric, to which it had confined its efforts.

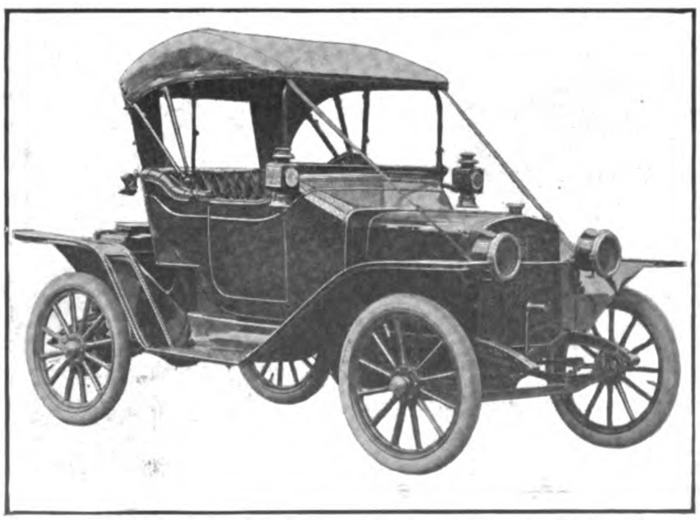

Fig. 3—Showing the finished vehicle, known as Model F

It has been arranged at present to manufacture but one model —that being of the runabout type—and to add others as the business increases. This car will be known as Model F and has a rating of 22-horsepower, the body being of the completely enclosed torpedo type, with a seating capacity of two and a rear platform large enough for a tool box and a double rumble seat. The wheel base is 86 inches, the tread 56 inches and the tires 30 by 3 inches. The steering wheel is on the left and the change gear lever in the center, so that the car can be entered from either side. There is not any emergency brake lever; the gearbox is a unit with the rear axle.

The motor is of the long-stroke type, having a bore of three and one-quarter inches and a stroke of five inches; this is a ratio of 1 to 1.54. The cylinders are cast en bloc. The crankshaft revolves on two bearings, and the valve action, including the timing gears, is completely enclosed. In Fig. 1 the exhaust side of the motor is shown with one of the valve cover plates C removed. The action may be readily inspected by removing the bolt B, which holds this cover in place, and the crankpit may be examined by removing the inspection cover D. The exhaust manifold E is provided with air cooling flanges, and is held to the cylinder casting by means of four through bolts F, which terminate in bosses in the inner casting. The magneto M is driven by the shaft S, which is rotated by and connected to the gear G.

On the right side of the motor, Fig. 2, the carbureter is seen to be fitted within the base casting, the object being to preheat the mixture to insure vaporization. The short intake pipe P is connected to the manifold M at H, the manifold being held to the cylinder casting by means of three studs, B. On this side of the engine the oil filler pipe F and the oil level glass G are located.

The cooling system is of the thermo-syphon type, with ample water jackets and fan in the flywheel. The intake is at I and the outlet at T. The radiator has a height of 23 inches and a width of 24 inches.

The lubrication is effected by means of the circulating splash system, the oil being maintained at constant level and circulated by means of a pump, the position of which is indicated by O, Fig. 2. The oil reservoir is in the lower part of the crankcase.

The clutch is of the cone type G, Fig. 5, with a self-contained thrust and an adjustable, grease-tight universal joint of hardened steel. A short shaft with a universal joint at each end connects the clutch with the forward end of the propeller shaft within the torsion tube, a considerable change in alignment being allowed by these joints. The propeller tube P is supported at the rear by the gearbox.

The gearset is of the three-speed, selective, spur-gear type, mounted on roller or plain bearings as specified by the purchaser. The gears are of chrome vanadium steel, and are hardened to prevent wear. The jackshaft and pinion shaft are of the same material as the gears. Upon the pinion shaft are mounted the sliding gears, which are held in position by four integral keys. The gearbox is divided vertically, so that the gears and shafts may be removed by simply unbolting the case. The rear half is integral with the axle housing.

The rear axle is of one-piece construction, with a cap at the rear which permits of the removal of the differential. Roller bearings support the differentials at either side and the thrust is taken by two ball bearings. The pinion and bevel gear are adjustable in both directions.

The steering gear, shown in Fig. 4, of the irreversible worm-sector type, is mounted on the left side of the frame. The steering wheel is 16 inches in diameter. The post is nclosd in a stationary black enameled tube. The right pedal R operates the external brake and the left pedal first disengages the clutch and then by a continuance of motion applies the internal brake, a slight forward motion of this pedal locking it in any desired position.

An accelerator pedal controlled by the right foot regulates the carbureter, and an adjustment just above the pedal determines the lowest speed possible when the foot is removed. The two brake rods extend from the control levers to the equalizers, located back of the axle, through the center of the chassis. This gives a concealed braking arrangement. The brake drums are 10 inches in diameter and 1 1-2 inches wide.

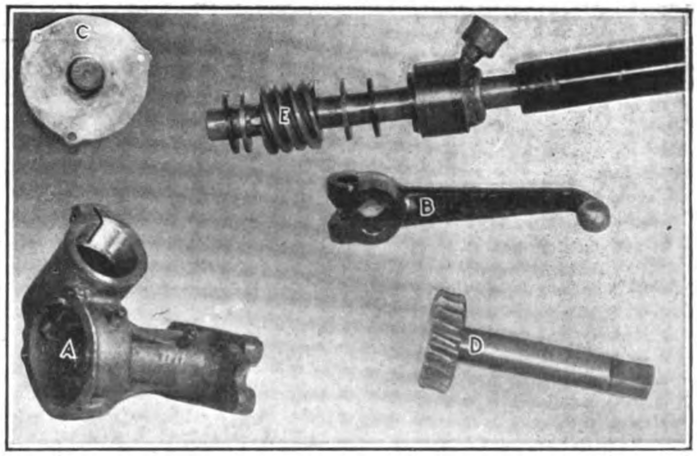

Fig. 4—Steering details: A, box; B, drop arm; C, cover; D, sector; E, shaft and worm

The front springs, 33 inches in length, one and one-half inches in width, are of the semi-elliptic form and are nearly flat. The rear springs, one and one-fourth inches in width and 37 inches in length, are of the elliptic style, tilted at the top toward the rear and hang under the axle. The passenger weight is well forward of the rear axle and the springs are mounted upon swivel seats to allow freedom under all possible conditions.

The equipment of the car is illustrated in Fig. 3, which shows the finished vehicle. It includes top, windshield, three oil lamps, two gas lamps, generator, horn and tool kit.

Tire Pointer for the Automobilist

A motorist may find that an inner tube has been injured and perhaps ruined from no apparent cause. Upon examination small holes will be found in its surface, the only logical reason for their presence being apparently poor tube material. This, however, is seldom the cause, says a Michelin expert, the real trouble lying with the motorist. He has carelessly fitted the tube allowing small particles of mud and dirt to enter the envelope, the air pressure from within the tube and the external pressure combining to grind the foreign matter into the tube.

When fitting a tire it is not enough to simply clean the envelope and tube. Care should be taken to admit no mud or sand during the operation. The tire levers should not be left lying on the ground as they will collect dirt which may find its way into the envelope.

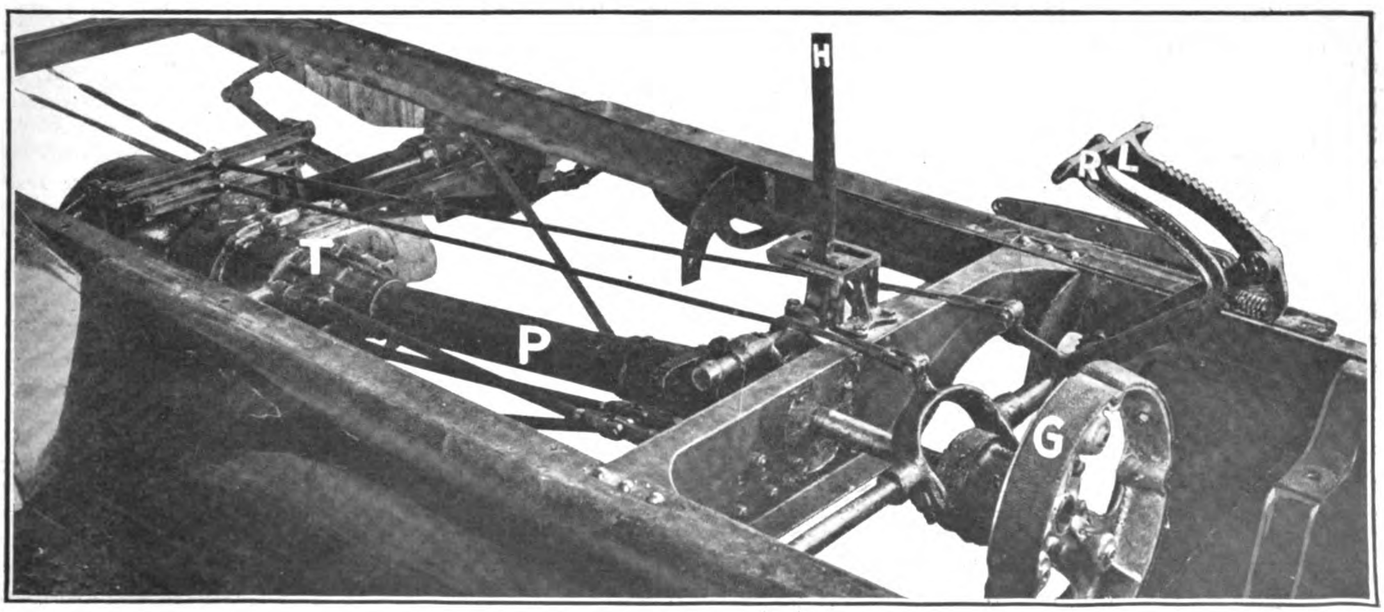

Fig. 5—View of rear end of chassis, showing clutch and transmission

News of the Week Condensed

CHRISTCHURCH, N. Z.—New Zealand's latest dreadnought, illustrated above, is built in this country by the Willys-Overland Company, of Toledo. The squadron of Overland cars that are following the dreadnought are also products of the same factory. The picture, which was taken during the carnival precession in Christchurch, represents a single shipment of Overland cars consigned to the New Zealand Farmers' Co-operative Association.

LOUISVILLE, KY.—The Wilder Motor Car Company has acquired the agency for the Everitt car in Kentucky.

KENOSHA, WIS.—Benjamin F. Windsor, president of the Windsor Spring Company, died last week at the age of 52 years.

INDIANAPOLIS, IND.—The Finch & Freeman Auto Company, which handles the Auburn, De Tamble, Clark and Richmond cars, has moved to 519 North Capitol avenue.

WASHINGTON, D. C.—Pending the selection of a salesroom in the down-town section, the Wilson Company, which handles the Cole and Krit lines, has taken temporary quarters at 1018 Connecticut avenue, N. W.

BOSTON, MASS.—E. P. Blake, who handles the McIntyre trucks, is dickering for the Corbin agency which was recently relinquished by the White, Ware & Leatherbee Company. Mr. Blake has also added the Blake car to his line.

MILWAUKEE, WIS.—Al. Reeke has succeeded A. W. Shattuck as sales manager of the local branch of the Thomas B. Jeffery Company. His territory will include, besides Milwaukee, practically all of Wisconsin and Upper Michigan.

PHILADELPHIA, PA.—The Gawthrop & Wister Company has recently secured the agency for the Brush car in the Quaker City.

MILWAUKEE, WIS.—The Smith-Hoppe Auto Company has completed arrangements for handling the Oakland car in Milwaukee and vicinity.

AKRON, OHIO.—The Miller Rubber Company has bought attractive land on the Manchester road in Kenmore, near here, to give room for factory expansion.

INDIANAPOLIS, IND.—One hundred employees of the Maxwell-Briscoe Motor Company have purchased 26 acres of land at Newcastle, Pa., upon which they will build cottages for their own use. The price paid for the land was $500 an acre, the entire amount having been subscribed by the factory employees.

RACINE, WIS.—The Mitchell-Lewis Motor Car Company has filed articles of incorporation for four branch houses, at Seattle, Atlanta, Kansas City, and Philadelphia. The capital stock of each of the companies is $10,000, and the incorporators in each instance are the same—C. A. Armstrong, G. V. Rogers and F. L. Mitchell.

BOSTON, MASS.—The Jackson car will hereafter be handled in the Hub through the agency of a factory branch, a company having been incorporated under the title of the Jackson Motor Car Company, of Massachusetts, with H. A. Matthews, treasurer of the Jackson Company in Michigan, as president. M. H. Bates, who formerly handled the car in Boston and Brockton, has been made treasurer, and J. L. Judd secretary and general manager. Ira Russell, formerly foreman of the Jackson factory, will have charge of the repair department.

BOSTON, MASS.—The Lowe-Howard Company, agent for the Krit and Correja cars, is preparing to give up the motor business. When the stock is disposed of the company will dissolve. The Krit line has been taken on by Willard M. Jenkins, who handles the Mitchell and Abbott-Detroit, in Boston.

OMAHA, NEB.—On account of the large number of Omaha dealers who desire to exhihit their cars at the Nebraska State Fair, the third annual endurance run of the Omaha Motor Club, which was originally scheduled for September 6-9, from Omaha to North Platte and return, a distance of 750 miles, has been postponed for a week, the new date being September 12-15.

FINDLAY, OHIO.—There is some trouble in conjunction with the present receivership of the Norwalk Motor Company. H. L. Stewart, who was appointed receiver by Judge Lee, has been succeeded by A. J. Schurr, of Cleveland, who was appointed by Judge Killits, at the instance of certain creditors. Some of the stockholders are now endeavoring to have Mr. Schurr removed and Mr. Stewart reappointed.

LOUISVILLE, KY.—Kentucky and Tennessee automobile dealers—120 strong—boarded a special Pullman train last Wednesday and went to Detroit where they were the guests of the Studebaker Corporation for two days. They made merry at luncheons, dinners, theatre parties, automobile rides and excursion trips and inspected the E-M-F and Flanders factories. W. W. Beeson, of this city, was in charge of the Kentucky delegation, which numbered fifty-four. The remainder of the dealers were from Tennessee and in charge of E. H. Jacoby, the Studebaker representative at Memphis.

WINNIPEG, MAN.—Last week 202 orphans of Winnipeg were treated to their annual automobile ride by members of the Winnipeg Automobile Club. They enjoyed a full day's outing with picnic and a programme of juvenile sports thrown in. Sixty cars were donated for the occasion.

BOSTON, MASS.—The Boston Automobile Dealers' Association is out with a booklet containing its preliminary announcement of the Tenth Annual Show, to be held in that city during the week of March 9-12, 1912. The booklet contains the rules and regulations governing the application for and allotment of space, including floor plans of Mechanics' Building and the necessary blanks.

INDIANAPOLIS, IND.—The Indianapolis Trade Association will make its ninth trade extension trip September 26 and 27. A special train will be used and about 150 members of the association and a brass band will make the trip, visiting retail dealers and distributing advertising matter. On the evening of the 26th the Fort Wayne Commercial Club will be host for the party. Places to be visited include Royerton, Shideler, Eaton, Hartford City, Montpelier, Keystone, Poneto, Bluffton, Kingsland, Ossian, Fort Wayne, Decatur, Monroe, Berne, Geneva, Briant, Portland, Ridgeville, Winchester, Lynn, Fountain City and Richmond.

CINCINNATI, O.—The second establishment representing Cincinnati automobile interests will soon be in operation in Canada—the pioneer having been the Schacht Company. The invader this time is the Ohio Motor Car Company, whose president and general manager, Charles F. Pratt, is now in Canada on a tour of inspection. He will probably locate and effect arrangements for the new plant to be in active working order in the very near future. Vice-President Schafer confirmed the report in regard to the mission of President Pratt and stated it had become almost a necessity by reason of the large and increasing Canadian business of the company.

NEW YORK CITY—The new United States Rubber Company building, now being erected at Broadway and Fifty-eighth street, was projected primarily to afford adequate quarters in a convenient uptown location for the main offices of the United States Rubber Company, as well as selling space in the automobile district for the United States Tire Company. The latter will occupy the store, with storage space beneath, while the United States Rubber Company will occupy the upper portion of the building.

The arrangement of offices is such that any number of offices may be thrown together, en suite, so as to meet any possible demands for floor space.

The construction of the building is in accordance with the best present day practice and particular attention has been paid to the methods of fireproofing. The foundations of the building are fully waterproofed.

The mechanical equipment of the building includes complete independent heating plant with vacuum circulation, complete standpipe equipment for fire protection, vacuum cleaner plant for the entire building and electrically operated elevators of the gearless traction type.

Each floor contains approximately 6,300 square feet, if undivided. Subdivided, each floor provides seventeen offices, varying from the smallest single office of 280 square feet to the largest single office, 630 square feet.

SYRACUSE, N. Y.—Entries for the second annual Watson Cup run are pouring into the office of the Automobile Club of Syracuse, assuring the promoters that a record field will get away in the tour to Koenig's Point next week in competition for the handsome silver goblet presented to the club by B. F. Watson. The contestants are to leave the city at 8:30 a. m., driving to Koenig's Point, on Owasco Lake, where dinner will be served. The committee will award the $100 trophy to the contestant coming nearest the secret time. The club also offers a silver trophy to the woman driving her own car who comes nearest to the secret time.

Automobile Incorporations

AUTOMOBILES AND PARTS

ALBANY, N. Y.—Mohawk Valley Automobile Co.; capital, $5,000; to make automobiles. Incorporators: Wm. E. Milbank, Agnes G. Waldron, Frank S. Weis.

COLUMBUS, OHIO—Toledo Annealing Charging Truck Mfg. Co.; capital, $10,000; to manufacture freight automobiles. Incorporator: John J. Blum.

DETROIT, MICH.—Lozier Motor Co., increased its capital from $2,000,000 to $3,000,000.

GROVE CITY, PA.—Bessemer Motor Truck Co.; to manufacture automobile trucks. Incorporators: I. N. Lewis, J. E. Marquis, E. J. Fithian, L. M. Monroe, A. N. Allen.

HACKENSACK, N. J.—American Automobile Co. of Philadelphia; capital, $50,000; to build motor cars. Incorporators: Ralph D. Earle, Geo. M. Brewster, John R. Ramsey, Wendell J. Wright.

HENDERSON, N. C.—Corbitt Automobile Co.; capital, $250,000; to make automobiles. Incorporators: R. J. Corbitt, D. Y. Cooper, J. B. Owen.

INDIANAPOLIS, IND.—Fisher-Gibson Co.; capital, $50,000; to manufacture automobiles and accessories. Incorporators: Carl G. Fisher, Cecil E. Gibson, Will J. Dobyns.

JERSEY CITY, N. J.—Marquette Co.; capital, $10,000; to manufacture automobile motors. Incorporators: B. S. Mantz, H. A. Black, John R. Turner.

LANSING, MICH.—American Motor Castings Co.; increased capital from $200,000 to $250,000.

MARTINSBURG, W. VA.—Norwalk Motor Car Co.; capital, $300,000; to manufacture and sell automobiles. Incorporators: F. A. Minor, Gray Silver, S. P. Hopkins, H. L. Alexander, T. W. Martin, G. W. McKown, Leon H. Ware.

NEWARK, N. J.—E-M-F and Flanders Newark Sales Co.; capital, $10,000; to sell pleasure cars.

NORFOLK, VA.—Coburn Motor Car Co., Inc.; capital increased from $10,000 to $50,000.

PITTSBURGH, PA.—Lang Motor Truck Co.; capital, $25,000; to build freight automobiles. Incorporators: Edward L. Atkinson, Elias Lang, Rupert L. Border.

PORTLAND, ORE.—Braly-Dubois Auto Co.; capital, $5,000; to handle automobiles. Incorporators: J. C. Braly, D. S. Dubois, Russell E. Sewall.

United States Rubber Company building now being erected in New York City

AUTOMOBILE GARAGES, ACCESSORIES, ETC.

AKRON, OHIO—Standard Tire Protector Co.; capital, $50,000; to make tire protectors. Incorporators: H. M. Coulter, B. O. Barber, O. J. Ballender, D. J. Kooneo, H. A. Lane.

ATLANTA, GA.—Mitchell Motor Co.; capital, $10,000; to sell automobiles. Incorporators: C. A. Armstrong, G. V. Rogers, F. L. Mitchell.

CHARLESTON, S. C.—King Automobile & Repair Co.; capital, $5,000; to buy, sell and repair motor vehicles. Incorporators: W. A. King, S. B. King, Jr., R. M. Lofton.

CINCINNATI, OHIO—Hayes & Havons Co.; capital, $15,000; to operate a garage and rent automobiles. Incorporators: Gus L. Hayes, Geo. C. Kuhn, C. F. Havons, Louis M. Pink, Leo. R. Wise.

CLEVELAND, OHIO—Eagle Lubricant Mfg. Co.; capital, $25,000; to make lubricating oils and grease. Incorporators: Chas. F. Maybery, James Graham, F. M. Potter, J. R. Ferguson, Oscar L. Tafe.

DAYTON, OHIO—Air Friction Carbureter Co.; increased capital from $10,000 to $20,000.

KANSAS CITY, MO.—Mitchell Motor Co.; capital, $10,000; to sell automobiles. Incorporators: C. A. Armstrong, G. V. Rogers, F. L. Mitchell.

LIMA, OHIO—Lima-Overland Co.; capital, $10,000; to sell automobiles and accessories and conduct a garage. Incorporators: Samuel Roeder, Howard W. Pears, George E. Bayley, Leo Roeder.

NEW ORLEANS, LA.—Kreher Auto Co.; capital, $10,000; to sell automobiles. Incorporators: Charles Kreher; Bertha Kreher.

PHILADELPHIA, PA.—Mitchell Motor Co.; capital, $10,000; to sell automobiles. Incorporators: C. A. Armstrong, G. V. Rogers, F. L. Mitchell.

PITTSBURGH, PA.—Mutual Wind Shield Co.; capital, $25,000; to make wind shields and accessories. Incorporators: A. J. Kraber, Geo. F. Ferrier, Lorry Poffenberger.

PORTLAND, ORE.—Auto Painting & Exchange Co.; capital, $25,000; to do a general business in automobiles. Incorporators: John Dumbell, Winnie Fleetwater, Henry O. Proebstel.

SEATTLE, WASH.—Mitchell Motor Co.; capital, $10,000; to sell automobiles. Incorporators: C. A. Armstrong, G. V. Rogers, F. L. Mitchell.

ZANESVILLE, OHIO—Zanesville Central Delivery Co.; capital, $10,000; to conduct a delivery business. Incorporators: E. B. Wadley, H. L. Garrett, B. V. L. Slack, William A. Frost, S. H. Sturts.

OF INTEREST to the INDUSTRY

PHILADELPHIA—The United States Motor Company has purchased the salesroom and service building at 216-218-220 North Broad street, formerly occupied by the Packard Motor Company. The building is one of the show places of the automobile trade of Philadelphia. Immediate possession will be taken by the United Motor Philadelphia Company, which is the Quaker City branch of the United States Motor Company. It will become the home of the Columbia-Knight and Maxwell cars as well as Sampson freight and delivery motors. All departments will be enlarged, furnishing room for all the models sold by the branch. The floor space will be four times as great as in the present location at 207 North Broad street. The enlargement of all departments will be made immediately and a full line of parts for all the company's cars will be carried in stock in a spacious parts department. The repair department will embody a main shop 200 x 50 feet, and another floor of equal size will be available for the storage of finished repair work. The maintenance of Sampson trucks will be conducted on another floor.

Philadelphia home of the United States Motor Company

ZIONVILLE, IND.—Marion & Stutz will represent the Cole line in this city during the coming twelvemonth.

PITTSFIELD, MASS.—The Cortland Motor Wagon Company is removing its plant from Cortland, N. Y., to this city.

SYRACUSE, N. Y.—The J. H. Valentine Motor Car Company has taken on the Syracuse agency of the Paige-Detroit.

EVANSVILLE, IND.—Harry P Mammen, of this city, has been appointed sales manager for Cole cars in Eastern Indiana and Western Ohio.

ST. LOUIS, MO.—The General Motor Car Company, 3952 Olive street, has been appointed Missouri distributor for the Cole car for 1912.

WASHINGTON, D. C.—An agency for the Stutz car has been established in this city by J. H. Ebersole at 1521 Fourteenth street, N. W.

READING, PA.—The Park Garage, which handles the Cole line in this city, has moved to new quarters at Eighteenth street and Perkiomen avenue.

CLEVELAND, OHIO.—The Standard Welding Company will open a branch office in the Ford Building, Detroit, Mich., September 11, with C. E. Miller in charge.

DETROIT, MICH.—The district representation of the Westcott cars in Michigan, Northern Indiana and Northern Ohio, will in the future be looked after by A. K. McCluny, with headquarters in this city.

LOUISVILLE, KY.—The United States Tire Company will open a wholesale branch at 904-906 South Third avenue, with H. G. Moesta in charge.

MILWAUKEE, WIS.—The Schreiber Motor Car Company has been appointed general distributor of the Stegeman motor truck for Wisconsin and the Central Western States.

MILWAUKEE, WIS.—G. P. Hewitt, former manager of the Buick branch in this city, has been appointed district manager of the Westcott Company in Minnesota, Wisconsin and Iowa.

TACOMA, WASH.—George A. Stewart, formerly sales manager of the Pacific Car Company, has been appointed district manager for the Everitt Northwest Company, with headquarters in Tacoma.

DES MOINES, IA.—H. B. Groves, manager of the United Motors Des Moines Company, has resigned. He will devote his interest to the Interstate Supply Company, of Sioux City, of which he is owner.

NEW YORK CITY.—C. F. Splitdorf has opened a branch office in Kansas City, Mo., at 1823 Grand avenue. E. A. Kelley, who for some years has had charge of the firm's San Francisco business, will be at the head of the new branch.

SEATTLE, WASH.—C. G. Arnold, formerly connected with the New York agency of the Pope-Hartford, and with the Keats Auto Company, of Portland, Ore., has become manager of the Olympic Motor Car Company, of Seattle.

INDIANAPOLIS, IND.—R. P. Henderson, formerly sales manager of the Parry Buggy Company, has assumed the vice-presidency of the Henderson Motor Sales Company, general agents for the Cole. Mr. Henderson is a brother of Charles P. Henderson, general manager of the Henderson Company.

LOUISVILLE, KY.—The Racine Auto Car Company, formerly located at 647 South Fourth avenue, has moved its salesroom and offices to Third avenue near Breckenridge street.

INDIANAPOLIS, IND.—The Empire Motor Car Company has decided to invade Japan, an agency having been established in that country with T. Laffin, of Yokohama, in charge.

PHILADELPHIA, PA.—The Jackson-Marion Sales Company, at 634 North Broad street, has closed a contract for the local representation of the Stutz car for the coming year.

TACOMA, WASH.—Having recently acquired the agency for the White cars in Southwestern Washington, J. F. Hickey has established the White garage at 750 South C street.

ATLANTA, GA.—The Long-Henderson Company, 226 Peachtree street, Cole distributors in the southeastern section of the United States, has changed its name to the Cole Motor Company, of Georgia.

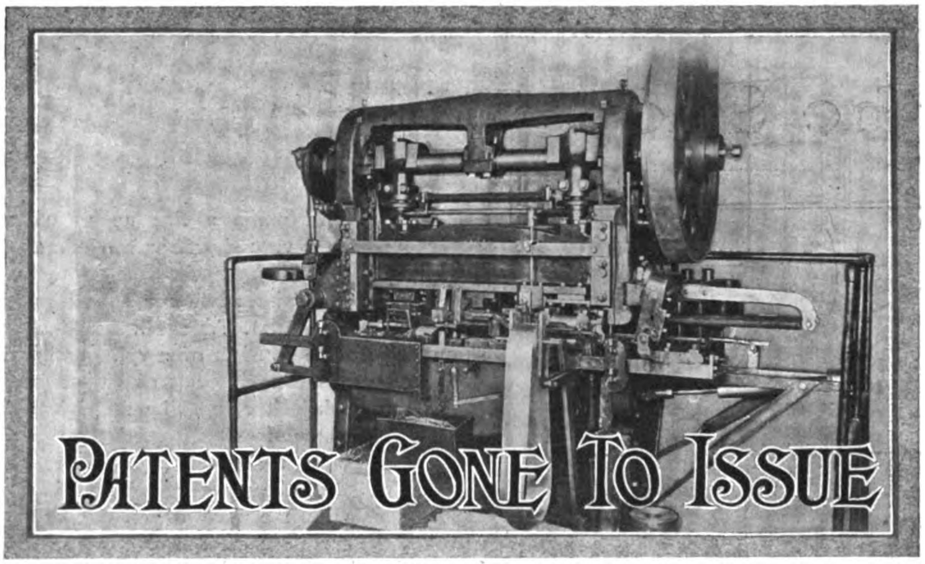
CLEVELAND, OHIO.—The actual working force of the Peerless Motor Car Company now numbers over 2,200, not including office employees or executives. A number of departments are working day and night.

BROOKLYN, N. Y.—E. J. Montigny has closed a contract with the Abbott Motor Company of Detroit, Mich., as wholesale and retail distributor for the city of Brooklyn and Long Island. He has organized a company for the purpose of carrying on the business.

RICHMOND, IND.—The Westcott Motor Car Company has announced that the selling arrangements with the Henderson Sales Company of Indianapolis have been cancelled. Henceforth the sales of the Westcott will be handled from the factory, and an independent sales organization will be built up throughout the country.

BOSTON, MASS.—Morton H. Luce, former manager of the Boston Velie branch, will shortly assume the management of the company's Chicago branch, handling the sale of pleasure cars and trucks in Illinois, Wisconsin, Michigan, Indiana and Ohio. The Velie interests in New England will in the future be looked after by Harold D. Bornstein of the Boston branch.

DETROIT, MICH.—The Universal Motor Truck Company has appointed the Lindsay Motor Company, 3327 Locust street, distributors for the St. Louis territory. The Hodgins-Fosdick Motor Company, Inc., Chalmers dealers at Spokane, Wash., have taken on the agency for these trucks in Eastern Washington. Thomas Black will look after the interests of these vehicles in Winnipeg, Manitoba.



CAR TRUCK—Being a form of suspension for motor vehicle loads.

2. The patent covers a car truck (Fig. 1) having a frame with side bars, links pendant from the side bars and rigidly connected therewith, springs supported by said links, a cross bolster, longitudinally extending equalizing bars and means for pivotally supporting the bolster on the equalizing bars and the latter on the springs.

No. 1,000,480—To Walter S. Adams, Philadelphia, Pa., assignor to the J. G. Brill Co., Philadelphia, Pa. Granted August 15, 1911; filed May 19, 1909.

CARBURETER—Containing such features as prevent flooding of the carbureter while operating.

2. This patent relates to a type of carbureter (Fig. 3) having an enclosing casing in which the float chamber and a fuel valve casing are contained and which has an air inlet and a mixture outlet, means being provided to keep the fuel in the float chamber at the desired level. A valve rotatably mounted within the valve casing; the valve has a port adapted to register with an elongated slot communicating with the float chamber below the fuel level, and this slot and the port are adapted to communicate by means of a fuel passage. Through this connection the fuel flows from the float chamber, being received by a cup-shaped member below the slot, the cup projecting above the fuel level existing in the float chamber, which arrangement prevents the carbureter from being flooded.

No. 1,000,518—To John Harris, Cleveland, O. Granted August 15, 1911; filed September 8, 1908.

STORAGE BATTERY AND PROCESS OF TREATING SAME—Specifies the constructive elements of an accumulator and chemical treatment therefor.

This patent protects the application of electrolytically active finely divided iron, or some other metallic material, intimately associated, with bismuth or bismuth amalgam. The process of treating the active metallic material consists in soaking the pockets containing it in a solution of bismust trichloride in acetone.

Thomas A. Edison, Llewellyn Park, Orange, N. J., assignor to Edison Storage Battery Co., West Orange, N. J.; granted August 8, 1911; filed March 20, 1908.

STARTING DEVICE—Being a safety crank for starting internal combustion engines.

In Fig. 2 is shown the cranking mechanism consisting of a rotatable element or shaft, encircled by a coiled spring which in turn is encircled and connected to a sleeve, the spring having a ratchet disc connected to one of its ends. The sleeve is encircled by a second spring to which is connected a rotatable member and this to a stationary one, the latter carrying a pawl which engages the ratchet disc above mentioned.

No. 1,001,303—To Samuel T. Reeves, Albany, Wis. Granted August 22, 1911; filed September 26, 1910.

RESILIENT VEHICLE TIRE—This is a tire to supplant pneumatics for automobile uses.

4. The patent covers a vehicle tire comprising a case tube formed with corrugations on its inner portion and split at its inner periphery. There are provided resilient walls having recesses open at their inner sides and forming a series of rounded cavities with the corrugations above mentioned. These cavities take up resilient balls which lend to the tire its elastic feature.

No. 1,000,165—to John B. Fischer, Chicago, Ill.; granted August 8, 1911; filed October 14, 1910.

DRIVING MECHANISM—Being of the friction wheel type.

3. The patents protect the combination, in a friction transmission, of a pair of opposed friction discs, a pair of friction wheels between the discs on a fixed common axis and means to bring the two wheels simultaneously into contact with opposite discs and on opposite sides of the disc axes.

No. 1,000,632—To Wilson Sprague, Portland, Me. Granted August 15, 1911; filed July 1, 1909.

GRINDER—Being a device for fitting valves in their places.

2. The valve grinder comprises a valve-engaging tool, a spiral shaft, an automatic clutch mounted on same, and actuator embracing the shaft, means for operating the actuator, including an adjustable crank, a momentum wheel on which the crank is mounted and transmission devices for operating the wheel mentioned and thereby the rest of the mechanism.

No. 1,000,553—To Peter Recconi, San Francisco, Cal. Granted August 15, 1911; filed February 23, 1911.

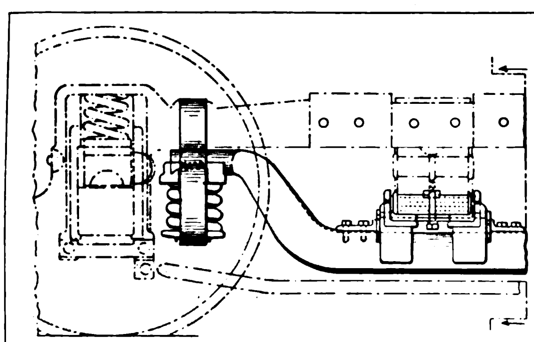


Fig. 1—W. S. Adams' car truck

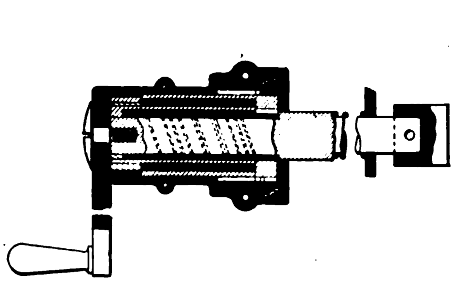

Fig. 2—S. T. Reeves' starting crank

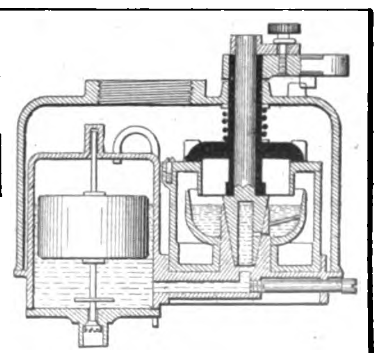

Fig. 3—J. Harris' non-floodable carbureter

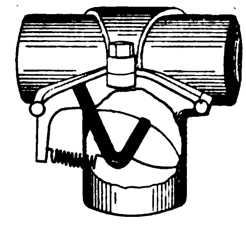
Seen in the Show Window

THE Stryker muffler cut-out, which is shown in Fig. CM, is easily attached to the exhaust pipe. A round hole is cut into the exhaust lead, and the body of the cut-out, which is seen in the figure below the exhaust pipe, is brought to bear against the opening so that the exhaust gases may freely enter the cut-out space. Then the cap of the cut-out is fitted around the portion of the exhaust pipe directly above the hole cut in it, and cut-out cap and body are joined by means of cap screws, one of which is shown in the accompanying illustration. The cut-out pipe, under normal circumstances, is closed by a butterfly held in position through a spring, but when the lever attached to the butterfly valve is pulled toward the motor—to the right in the illustration—the metal plate forming the valve is brought into such a position as to permit the exhaust of the motor to pass through the cut-out, instead of flowing through the muffler. The Stryker cut-out is operated by means of a cable and snap, actuated through a bronze pedal from the driver's seat. The cut-out is the product of C. W. Stryker, of 314 E. Onondaga street. Syracuse, N. Y.

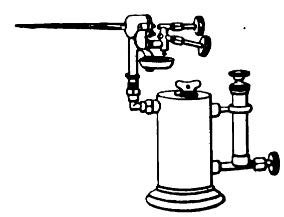
AT CN the Turner double-jet alcohol blowpipe is illustrated. The burner is mounted on a compound swivel so that the flame may be pointed in several divers directions. The tank is filled with alcohol which serves as the fuel, and instead of bellows being used, the air necessary to produce the needle-pointed flame is pumped into the flame by means of the hand pump arranged in the handle. The maker, Turner Brass Works, Sycamore, Ill., claims that a temperature of 3,000 degrees may be produced through the use of this torch.

COMPRESSION is an indicator of some important engine conditions and to measure its amount the Edelmann compressometer, illustrated at CO, has been constructed. The principle of this meter is not unlike to that of the tire gauge. For testing the compression of a cylinder, the spark plug is removed therefrom and the compressometer, which comes in all standard spark plug threads, inserted in its place. Then with the ignition cut off the engine is once turned over by the flywheel, and the compression in pounds which shows on the dial is noted. The operation is repeated on all the cylinders, so that in case one of them is at fault the fact will become obvious. A red hand records maximum compression. E. Edelmann & Co., of 49 West Kinzie street, Chicago, Ill., manufacture this device.

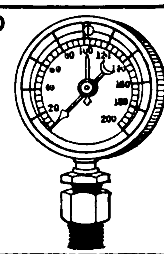
CM



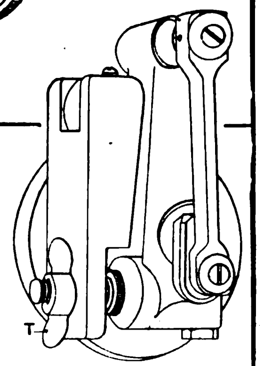
CN



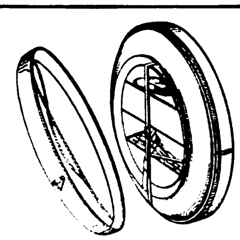
CO



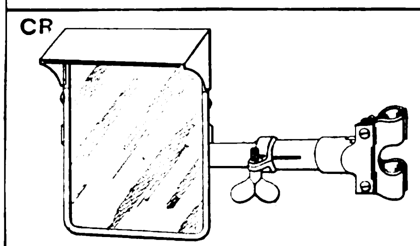
CP



CQ



CR



CM—Manner of Attaching Stryker Cut-out to Muffler
CN—Turner Double-Jet Alcohol Type of Blowpipe
CO—Edelmann Compressometer is Made in Spark Plug Threads
CP—Hart-Giant Tire Pump is Driven by the Motor
CQ—Argos Mirror Shows the Driver, the Cars Following Him
CR—Star Tire and Tool Case is of Large Capacity

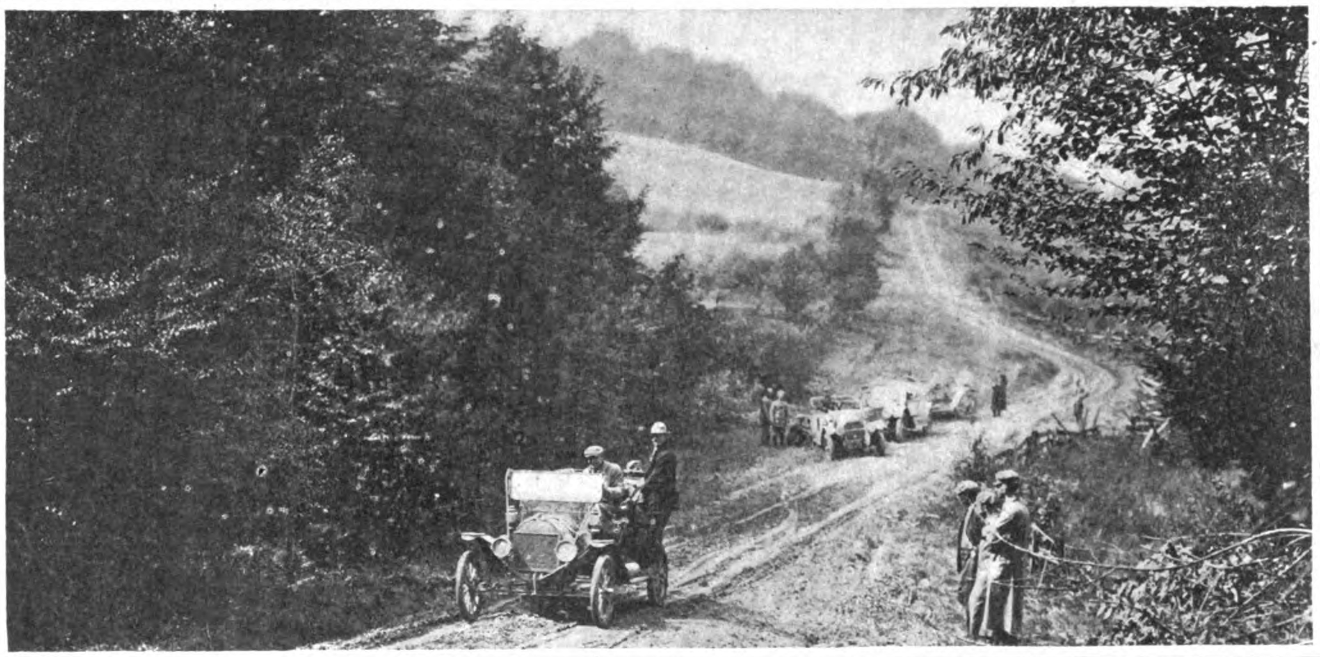
THAT it will pump a tire up to 90 pounds in a very short space of time with hardly any work on the part of the operator, is the claim made for the Hart Giant tire pump (CP). As the illustration shows, this pump consists of a cylinder in which a plunger is reciprocated by the action of a crankshaft rotated by a driving wheel. The pump is so mounted on the chassis frame by means of two brackets that the wheel of the pump comes in driving contact with the face of engine flywheel, if the thumb-screw T is given a turn. The 12-foot hose connection is connected up to the tire to be inflated, and the engine started and run at slow speed. A slight adjustment of the thumb-screw then brings pump wheel and flywheel into contact, whereby the plunger of the pump is reciprocated in its cylinder, compressing the air sucked therein, which is then led to the tire. The pump is made by Hart & Widder Co., 511 West Twenty-first street, New York.

CAPACITY of the "Star" tire and tool case, made by the Merchant & Evans Company, of Philadelphia, Pa., is two shoes, two inner tubes in inflated state, in addition to from four to six folded tubes, and separated by a partition from a space for spare tools and like apparatus. The "Star," which is shown at CQ, is light of weight, its metal skeleton being covered with a waterproof fabric. The illustration shows the inner space divided for tubes above and tools below a partition, while the shoes are strapped to the body of the case in the manner shown. A hook and the bottom and two side latches, together with a lock on the top, keep the contents of the case protected from theft or loss.

LOOKING backward for the cars following one's trail is the chauffeur's work at times, but this work is as uncomfortable as it is fraught with risk. To enable the driver to see the rear of the road without turning his eye away from the portion before him, the Argos mirror, shown at CR, is attached to the windshield post by means of the positive-grip bracket seen in the figure made of brass. The shaft contains a ball-and-socket joint, permitting the mirror to be brought into and held in almost any desirable position. The glass is a high bevel plate and so fastened to the frame that it may be replaced without difficulty. One of the main features of this mirror is the ease with which the frame may be removed from its shaft, to which it is held by a thumb-screw. This mirror is made by the Motor Car Equipment Company, of 55 Warren street, New York.

VOL. XXV NEW YORK—THURSDAY, SEPTEMBER 14, 1911—CHICAGO NO. 11

THE AUTOMOBILE



STARTING UP THE FIRST HEAVY GRADE OF THE LONG CLIMB ON BOSTON HILL WHERE MANY CONTESTING CARS CAME TO GRIEF

Oakland Wins Buffalo Sweepstakes

Flanders and Oakland Win Runabout Divisions

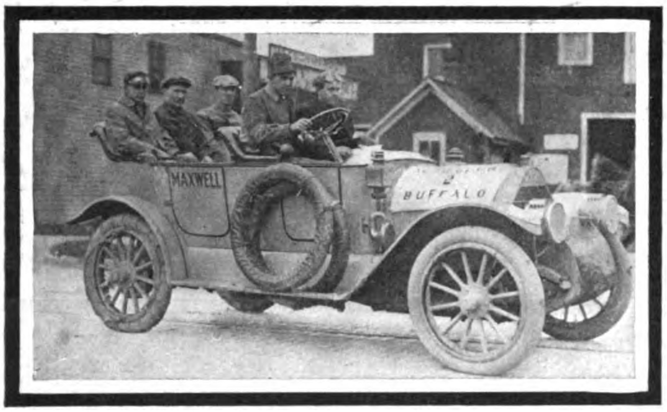
Maxwell and Lion Win Touring Car Classifications

BUFFALO, N. Y., Sept. 11—Oakland 24, a 40-horsepower runabout competing in Class 3A, proved the winner of the Laurens Enos trophy and the sweepstakes in the second annual reliability run of the Automobile Club of Buffalo, which was completed Saturday. The car was driven by Howard A. Bauer, contest driver of the manufacturing company, and had a clean score on the road and in the brake, clutch and motor tests. On final technical examination, which was unusually thorough and searching, the car was given 8 demerits for five loose rivets and bolts, a loose fan pulley and a slight leak in a water connection.

Bauer drove the car with exceeding skill and care over a route of 855 miles, laid out over a series of hills that were unprecedented in reliability work, and the conditions were further complicated by intermittent showers and downpours that rendered some of the hills tractionless. There were three mountains included in the route, respectively and respectfully, Buffalo Hill, Boston Hill and Clarkesburg Mountain. Bauer nursed his car over this trio and maintained his class schedule at every control. He of all the contesting drivers made a special effort toward uniform speed, varying only on the big hills, and making no effort to reach control ahead of time.

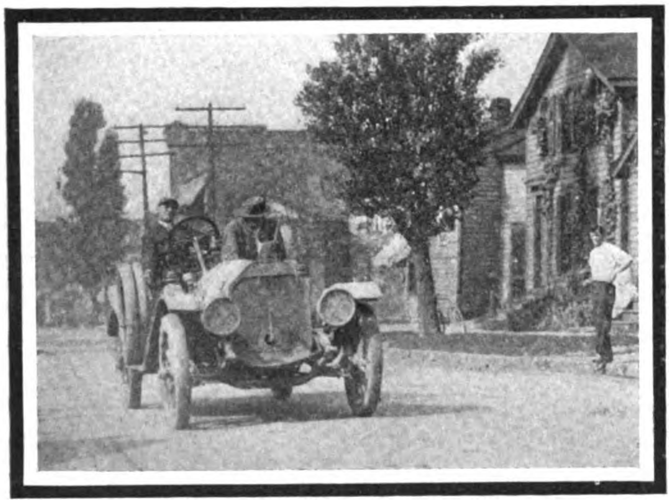
Flanders 4, driven by T. R. Bell, won the Class 1A division for runabouts with a total penalization of 48 points. Aside from its road penalties, which were the result of taking on water out of control, and lateness, this car was demerited 16 points on final examination. Four loose bolts, a broken fender and 5 points in the clutch test comprised the black marks. All were due to the bad roads, stiff hills and long schedule, and the showing of the car was most creditable.

Maxwell 2 won the 3A touring class with 51 demerits. These penalties were practically all accountable to troubles that had their origin in the carbureter and developed in greatest force immediately after a supply of high-proof gasoline had been taken on board at the noon control on the first day's run. Th[illegible] was different in quality than was appropriate for the carbureter adjustment, and resulted in considerable trouble for the car. In addition, the hills caused an extra drain on the water supply and gasoline consumption and renewals were necessary a number of times. In the final technical this Maxwell, which was driven



Maxwell "2," winner of the 3A class for touring cars and third in the general standing

Oakland 24, winner of Laurens Enos trophy in sweepstakes class



Oakland "24," the winner, being tested for brake efficiency by Chairman Edwards

by E. G. Gager, of the Pittsburgh branch of the United States Motor Company, was penalized 16 points. In the brake test the car slipped over the line 5 feet and Chairman Edwards, of the technical committee, discovered a broken lamp bracket, missing ignition terminal, leaky gasoline connection and two loose rivets.

The car showed fine speed on the roads and steadiness on the hills, but like every other contestant it was sharply tried by the first day's running.

Lion 6, winner of the 4A class, was heavily penalized through the breaking of a side member. This car was driven by Harry Blomstrom, from the Lion factory at Adrian, Mich., but was seriously handicapped throughout the run by a weak left rear spring. Blomstrom is an unusually skillful driver, but before the first day was over the car had laid the foundation for its ultimate demerits. The weak spring caused the car to pound on the rough roads, and this pounding loosened the drip pan under the engine. Blomstrom fixed it several times during the day and "took his points" for work. But the repairs could not be made in thorough fashion, and eventually, to make controls and stop the constant penalization, Blomstrom dropped the pan and went ahead. The second day was over comparatively dry roads and the car came through with few demerits, but on the third day water lay in pools on some sections of the route and, water splashing up past the place where the pan is held ordinarily, it short-circuited the magneto and led to considerable demeriting. On this day's run the Lion, at the head of the procession, picked up the pacemaker's flag at Levant, where a bridge had been washed out. The Pierce-Arrow pacemaking car, in going around the broken bridge, cut through the sod in a wet meadow and stalled for several hours. The Lion was obliged

to go along at high speed and thus probably aggravated its troubles. The final day nearly brought the car to grief in climbing the two mountains that lay this side of noon control. It is said that a horse has not climbed these hills in forty years, although there is some little travel on the down grade. It took all the Lion's power to get to the top and a big spurt of speed was necessary to make control. There it was discovered that a side-member was cracked, and in that condition the rest of the run was made. The car checked in 47 minutes late and its total penalization was 626, all of which was traceable to a weak spring.

Everitt 8, driven by Joseph Gardham, made a spirited fight for the class trophy in 3A division. Like all the rest of the contestants, the Everitt was crippled by the first day's run. The jolting caused a leaky pump and the engine ran hot. This aggravated carbureter troubles and an accident bent a spindle, causing further penalties in the final brake tests. The car had rather less trouble on the hills than its competitors, but the first day made a clean score impossible for any of the cars and weighed heavily upon the Everitt.

Maxwell 10, driven by Thomas Costello, suffered carbureter trouble the first day after getting the 70-proof gasoline, and was heavily penalized for work done in clearing and adjusting the carbureter. The car showed up well in the finals and but for the incident of the carbureter would have been near the front.

Ford 14, a factory car equipped with a touring body, performed very creditably. It was penalized 107 points all told, and certainly would have been entitled to the class trophy in the 1A touring division if it had carried its full load on all four days.

Through some oversight, however, the car was entered with the runabouts and on the first two days did not carry its quota of passengers required by the rules governing touring cars.

Ford 21, in the runabout class, finished in good style, driven by a member of the Automobile Club of Buffalo, M. W. Wolfe. Its road score was clean for the first two days, but the terrific strain of those periods became manifest in the latter portion of the run and Ford 21 had difficulty in getting home. Chairman Edwards found fifteen loose rivets and brake and motor troubles.

The Warren Detroit 26 was the only other car to finish, and it was severely penalized on technical examination. A spring horn and spring clip were broken and the emergency brake failed to hold by 39 feet. The car made an astonishing showing on the road during the last two days, coming through with a perfect score.

Accidents eliminated most of the other starters. The toughest luck of the tour was experienced by Maxwell 1, driven by Charles F. Munroe, local representative of the United States Motor Company. Last year Mr. Munroe won the Enos trophy in the

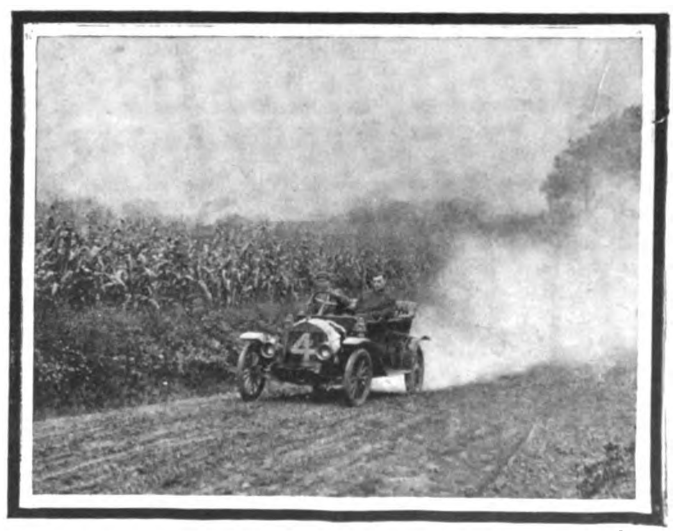
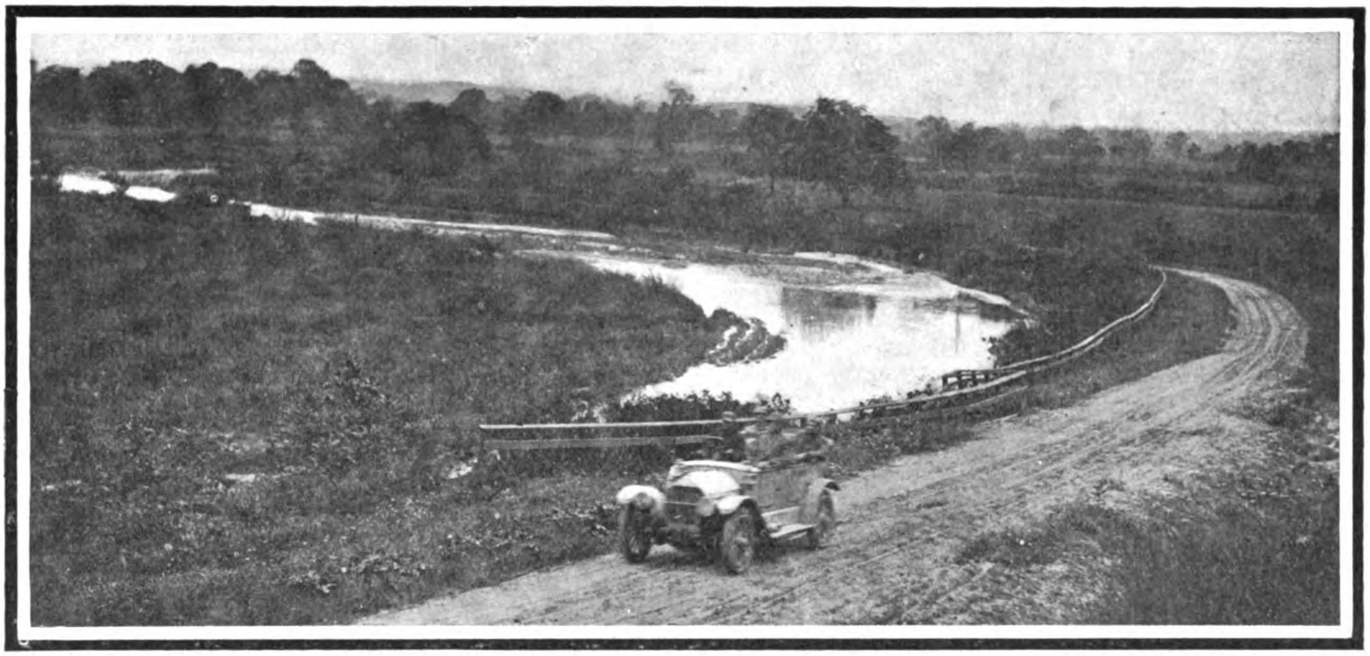
Looking north from the summit of a stiff hill not far from Cattaraugus

Lion 6, class winner, with the pacemaker's flag on third day



Flanders 4, winner in its class and second in the sweepstakes.



Maxwell 10, swinging through one of the level spaces included in the route of the tour's second day, showing character of the roads traversed

tour with a Maxwell car, and this year with one of the new Specials he announced that he was going after it again. The car led the procession to within 50 miles of noon control, when it collided with an Abbott-Detroit racing machine that was accompanying the caravan as a non-contestant. The rear axles of both cars were kinked and the Maxwell was badly disabled. Mr. Munroe was making temporary repairs to get as far as the noon control when the Schacht 11, contesting in the same class, came careering along, striking a hay wagon and rebounding against the crippled Maxwell. When the mud had settled it was found that the axle of the Maxwell was sheered, while the Schacht was put permanently out of commission with a similar injury.

Flanders 3 and 9 succumbed on the fourth day's run. The latter had a clean score the first and third days, and was penalized only 4 points on the second day for a spark-plug adjustment. During the same time its teammate received 3 demerits the first day for taking on water, while on the second and third days its score was clean. But on that fierce fourth day both the little cars withdrew. It was the Clarkesburg mountain that put them out of the running, both skidding from the road and smashing into trees in such position that they could not be repaired or extricated in time to continue. It was a curious fact that the winning Flanders was much more heavily penalized on the road than the pair that withdrew, although a large part of these points came as a result of the last day's run.

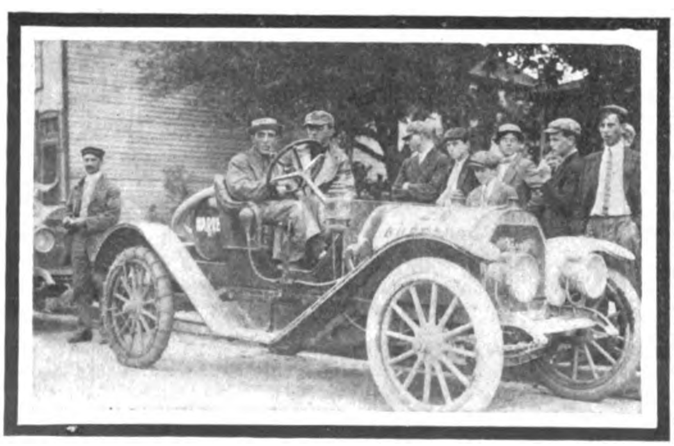
Ohio 12 had a stormy journey. It was the biggest and most costly car in the run and consequently had to labor harder on the hills, and in addition was obliged to make a 20-mile-an-hour schedule. The first day brought it 96 demerits for work on clutch, carbureter and in taking on supplies. The route was unfair to such a big car despite the fact that the Pierce-Arrow and Thomas six-cylinder cars were able to negotiate it. It did better the next day, but began to go back rapidly during the tremendously long run of the third day. Boston Hill got the Ohio's scalp after the car had skidded across the road and lay helpless near the foot of the mountain.

Paige-Detroit 27, a rather old model of this make, developed the only downright mechanical defect during the tour. The Paige was equipped with differential pinions of unequal hardness. This resulted in disablement on the first day which rolled up an imposing number of demerits against the car. Nevertheless, McFadden worked industriously on the car at night and was ready to start the next morning, not having rested for a minute. The car was given nearly 1,000 points, and the second day produced 291 more. The third day was better and the entrant had hopes of finishing, when Clarkesburg Mountain intervened and the Paige came back by freight.

It was a fierce contest over roads that would have furnished a tremendous test of stock automobiles under the best of weather conditions. But such conditions did not obtain. A deluge swept over the northern half of New York State on Tuesday night, and when the cars were called to the line at 6:30 Wednesday morning it was freely predicted that none would make night control within three hours of schedule. The course led to Buffalo Hill by a winding way. There is a sharp turn approaching the heavy grade and the cars had to proceed rather leisurely in the early part of the ascent. The hill is of flint, streaked with seams of blue clay, and in dry weather is simply a very steep, smooth mountain road over the hardest kind of bed. But on Wednesday it was different. The rain had dissolved considerable clay above the road and had washed it down upon the flint, so that when the cars approached the slippery bed had been covered to the depth of half an inch with this perfect lubricating substance. Chains were useless and all the cars fought it out on a basis of main strength. That they arrived at the top is a speaking testimony of the power of the modern stock automobile.

Beyond the hill were more hills, some of them quite as steep as Buffalo and some much rougher, but none like it. It was Buffalo that made clean scores impossible for such automobiles as contested, or, in fact, any others.

The first day's run was 207 miles, and four more were added by a detour. They were such miles as only Dai H. Lewis could select when he was in a selecting humor, and, to make



Warren-Detroit 26, which made a gallant showing and finished the situation worse, they were soggy and slippery and badly cut up in spots.

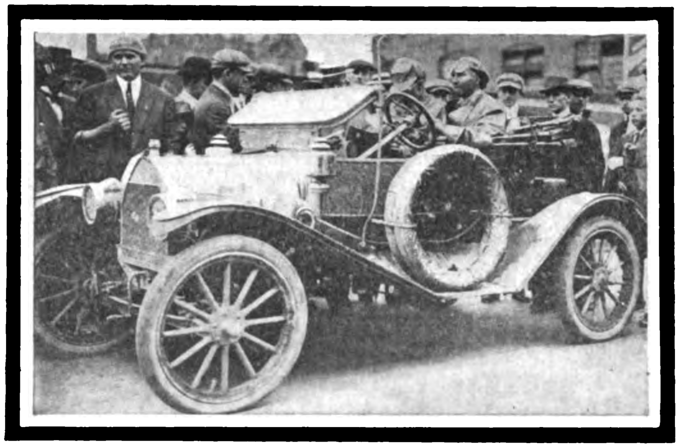
The second day proved to be the easiest of the tour, which is not saying much. The route was only 200 miles long, which required the Class 1A cars to travel 12 1-2 hours.

The third day was through some of the most magnificent road scenery in the world. From Buffalo to Bradford, Pa., the way was somewhat similar to that covered on the other days, but from Bradford to Warren, Pa., the landscapes deserve the attention of some master painter. The Automobile Clubs of Bradford and Warren take a just pride in the roads and see that they are maintained, but even with just ordinary roads the trip would be gorgeous.

But that is about all. From Warren back to Buffalo it was a grind and the day wound up with a mileage of 222. This was occasioned by two bridges being washed out. The first of these necessitated a change in route through the Iroquois reservation where the roads were trying, and the second brought the official pacemaker to grief. The Pierce-Arrow car that carried the referee stuck in the mud near Levant and the stiff wind that sprung up later in the day caused the confetti to be blown to the right side of a long stretch of good pike, thus leading the Lion, which had taken up the pacemaking, to make a wrong turn. All the cars followed, and as a result a big addition to the day's run was made.

The last day was the terror of the four. Weakened and racked by the strenuousness of the foregoing days, four cars bowed to the inevitable and retired during the morning.

The reason lay in the fact that Boston Hill and Clarkesburg Mountain are two of the stiffest ascents ever presented to automobiles for negotiation. Boston Hill came first on the itinerary. In the middle of summer, when no rain has fallen for a couple of weeks, Boston Hill might be used as a sort of ultimate test for hill climbing by automobile manufacturers. Few would even try to climb Clarkesburg. Each is long and 30 per cent. grades are not uncommon. In fact, several of the veteran drivers declared that the maximum grades were steeper. Over each of these hills is an arch of trees and the roadway, which is sometimes used for horse travel on the down grade only, is composed of blue clay. The tree arches serve to keep off the sun and keep in the moisture, and when the head of the procession reached the beginning of the Boston Hill there was no more traction to be had than there would be on the side of a house. Some tried it on low gear and others backed up the grade. Four cars failed to get up at all.



Ford "21," which looked like a winner in Class 1A until the final day of the tour

The clutch test was passed in good shape by all the cars, a few penalties of 5 points each being imposed.

Then came the final technical inspection by Chairman Edwards. It was of the fine-tooth comb variety and went clear to the vitals of all the cars.

It was a magnificent tribute to the sturdiness of stock automobiles of modern manufacture that as many as nine cars finished the run and that only six fell by the wayside.

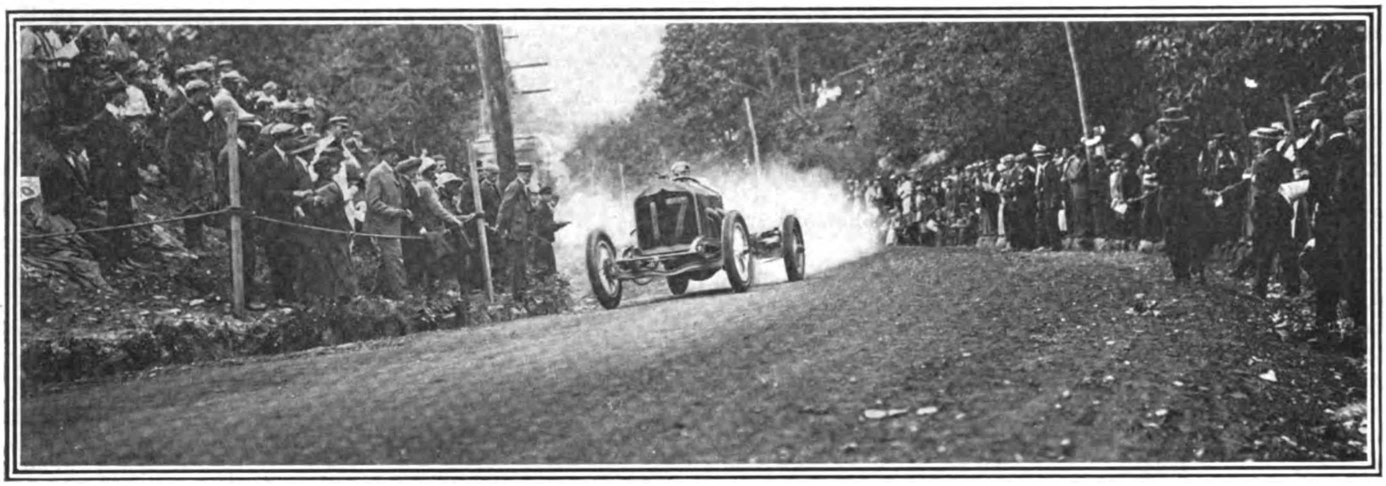
Maxwell Trio and Ford touring car in close order during the early part of the first day's running after passing East Aurora

National Stars at Port Jefferson

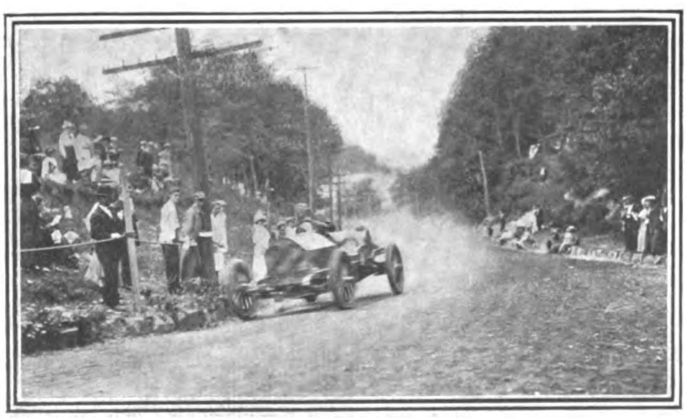


National 17, which proved the winner of two events on Saturday, making the severe turn at the elbow; Donald Herr driving

RIVALRY, friendly but intense, marked the second annual hill-climbing contest of the Automobile Club of Port Jefferson. The hill, a measured 2000-foot course, with a 400-foot flying start, was lined with the residents of Port Jefferson and the vicinity, who had come to view the contests in spite of the weather conditions—rain threatening all the afternoon. Additional interest was given the well-contested matches by an elbow located at about the center of the course, and of such an angle that the approaching cars were concealed from those who clustered about the finish line until they had rounded the bend and were on the final stretch. The manipulation of the curve proved to be a great factor in determining the time of the climb, for in many instances where the time of two rival cars was close it was noticed that the winner proved almost invariably to be the one who had made the better turn.

The gradation of the hill ranges from 6 to 16 per cent. At the start there is a sharp rise for about 800 feet; the slope then becomes easier until the bend is reached, at which point it attains the maximum. There were very few instances in which the contestants dropped to second speed, and when they did they were in all cases badly defeated. The changes of gear were made just above the elbow by the smaller cars.

No accidents of any consequence marred the afternoon's sport, the nearest approach to a disaster being when the National car No. 17 went through a hedge fence after having passed the finish line and while still traveling at a rapid rate. The car was checked just before reaching the steps of the veranda of a private residence and was backed out without any damage having been done except that to the shrubbery. The course was kept clear during the entire race by means of specially appointed police.



The Mercer car driven by Hughie Hughes, winning the event for its class in piston displacement

The events for small cars opened the races, the first car coming up the hill being one of the Fords. After this the different events were intermingled one with another, thus furnishing a variety. The first two events for stock cars were won by Ford cars, the second places in both these events likewise going to the Fords, four of which were entered by Messrs. Bishop, McCormick & Bishop. The Krit in the first event was the only car during the race whose official time stood over one minute, although there were several cars which went over this time in one of the two attempts which were allowed. The Krit car did not take a second trial in this event.

The National cars distinguished themselves by winning all the large events of the day, including the free-for-all for the beautiful Ardencraig trophy, besides the races in their class for sell-

Record for the Hill Still Stands

The Ford T, which finished first in its class for selling price

The Lion 40, driven by Apgar, which finished first in two events

ing price and piston displacement. The amateur event, won by the National 14, driven by W. J. Fallon, was protested by E. B Hawkins, a post-entry to this race. The protest was officially made in writing at the termination of the race, on the ground that the National car was not owned by the entrant for the required thirty days before the race. This matter will be decided later by the A. A. A., under whose auspices and rules the race was held.

The third event consisted of but two entries, a Lion car which won the race and a Correja which lost by about four seconds. Both these cars climbed the hill in far less time than that in which the climb was made last year by the winner of the corresponding event. In fact in every case except the free-for-all and that of stock cars selling from $1,601 to $2,000 last year's time was considerably bettered.

The fourth event was won by the Corbin, which had a margin of about ten seconds on its nearest rival, the Cole driven by Walter Blair. The Corbin was driven by the owner, H. B. Tucker. In this event the Velie car very nearly stalled its motor on the first attempt at the bend, taking over a minute and fifteen seconds to climb the hill. On the second attempt, however, the Velie made the climb in 46.25 seconds, taking third place in the race.

Very fine time was made in the fifth event, the National No. 14, driven by Herr, proving to be the winner by less than one second over the Mercer driven by Hughes. The Mercer did not take the bend as quickly as the National, losing considerable time on the skid. The National car held closer to the crest of the road, making a much prettier turn and saving time.

The stock car events on the card were most carefully observed by the automobile owners and prospective owners in the assembled crowd and while the representatives of these classes did not make as much noise as the speed creations that competed in the free-for-alls, their performances attracted considerable discriminating attention.

The free-for-all excited the liveliest interest. The assembled crowd wanted thrills and they got them in this race. The first car, a Mercedes-Simplex with chain-drive, thundered up the hill, seeming to gain speed every instant. Just as it reached the finish line it swerved into the gutter, breaking the timing wire and sending a shower of pebbles about the judges' stand. No damage was done the car, however, and the excitement soon quieted down while the necessary repairs were being made. It was in this race that the best time was made. The National car climbed the hill in 21.31 seconds, which was the fastest time of the day. This did not upset the record made last year by Ralph de Palma in a Fiat car as his time was 20.48 seconds.

When the other drivers learned the time made by Donald Herr in the National a number of them resolved to take advantage of the second opportunity to which they were entitled under the rules. The Mercedes-Simplex was among those which tried the

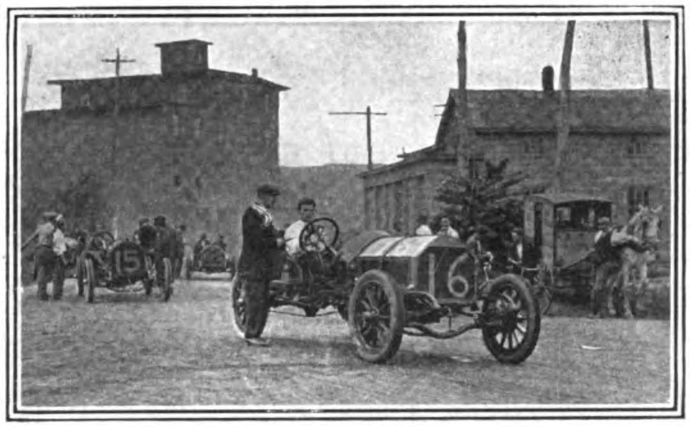
*Protested.

The Corbin car driven by Maisonville, which finished second in its class, approaching the starting line

National car which will win three events if protest is not allowed



Belcher receiving starting instructions while seated in his Knox car

second climb, and it again distinguished itself by scraping the gutter and carrying away the finishing wire. After having torn down the wire the car continued gaily on its way, concluding its performance by very nearly ramming a touring car filled with innocent spectators. The National's time was not touched and stood as the day's record, and with it went the possession of the Ardencraig Trophy.

The other races which were graded by piston displacement were won by the Lion car, driven by F. S. Apgar; Mercer, driven by Hughie Hughes, and National by Donald Herr (two races).

The amateur events, open only to residents of Port Jefferson and vicinity, excited great interest, and the attempts of the rival drivers to better each other's time were cheered by their neighbors who were gathered on the hillside. It was in the amateur race for cars selling over $2,001 that the protest was entered by E. B. Hawkins, who is postmaster of Huntington, a near-by town, against the National car driven by W. J. Fallon, the promoter of the race. Mr. Hawkins was second in his Knox.

A special event between a Ford and Metz 22 went to the latter rather handily.

The officials were as follows: Racing Committee, W. J. Fallon, A. O. Smith, G. E. Darling; Manager Parking Space, Paul B. Franklin; A. A. A. Representative, Frank G. Webb; Referee, A. R. Pardington; Judges, D. M. Gerard, Willard Bayles, Dayton Hedgess, Luther Chambers, C. B. Zabriskie, Carl S. Buer; Clerks of Course, W. J. Fallon, Tom Fallon, Arthur Burns; Starter, E. C. McShane; Assistant Starters, George Robertson, Jack E. Connell; Chief Timers, William Poertner, A. G. Inderreiden; Announcers, H. J. Fenn, H. J. Willetts, Will Robins, Jacob S. Dreyer; Technical Committee, A. F. Comacho (Chairman), Ben T. West, Henry Souther, A. F. Sammiss, J. H. Downer, F. C. Griswold, A. N. Randall, Thos. Fanning; Scorers, Steve Fallon, Leslie Davis, Chester Darling, Archie Graham, William S. Lawson; Entry Committee, William J. Fallon, George Darling. The timing was done by an electric trip wire and telephone made by Warner Instrument Company.

The race was a success in every way and will no doubt be repeated next year by the Automobile Club of Port Jefferson.

Speed Rates of Port Jefferson Winners

Following is a table of speed rates made by the winning cars in each of the fourteen events of the Port Jefferson hill climb:

Event.	Car.	Time.	M. P. H.
1	Ford	44.83	31.1
2	Ford	43.06	31.7
3	Lion	29.22	46.7
4	Corbin	32.90	41.4
5	National	24.45	55.8
8	National	21.31	64.0
9	Lion	27.57	49.6
10	Mercer	25.55	53.3
11	National	23.19	58.8
12	National	21.37	63.9
14	Corbin	34.56	39.5
15	National	25.30	53.9
16	Buick	33.43	40.7
17	Metz	39.38	34.7

Dealers' Week in Detroit

Studebaker and Ford Agents in Conference

DETROIT, MICH., Sept. 11—Dealers have been pouring into Detroit in a steady stream the past week, and the migration continues without any indication of waning interest or enthusiasm on the part of those who are doing the entertaining. This morning a delegation of nearly 200 E-M-F dealers from Texas and Oklahoma arrived in one of the Studebaker Corporation's specials for a two days' visit, and they will be followed, later in the week, by the Kansas City delegation.

More than 400 dealers were entertained by the Studebaker Corporation and the Ford Motor Co., alone, last week. The Ford visitors included dealers from Wisconsin and Iowa. The Badger State contingent was accompanied by six Milwaukee newspaper men. The visitors were entertained with a luncheon at the Log Cabin Inn, a spin to Grosse Pointe and a dinner at the Hotel Tuller in the evening.

Thus it has been one continual round of handshaking, explaining and entertaining, with luncheons every day and banquets every night. In addition to establishing a stronger personal relation between manufacturer and dealer, these visits have enabled the dealers to study the details of construction at first hand, and this knowledge, naturally, is bound to be a valuable asset in the selling of cars.

A party of 300 leading business men of the Upper Peninsula were the guests of the Detroit Board of Commerce, Wednesday and Thursday of last week, and were taken through the Packard and Chalmers plants, Thursday morning. The visitors were received by Lee Counselman, vice-president and general manager of the company, and they were escorted through the plant by officers and heads of departments. Each was presented with a souvenir in the form of a Chalmers watch fob.

The Cartercar Company is now occupying its handsome new building at Woodward and Hendrie avenues, which is a marked improvement over the company's old show rooms.

Harry Paxton and A. A. Crumley, both of whom are well known in local motor car circles, will go to Philadelphia as eastern distributors for the Warren Motor Car Co. They will do business under the style of the Paxton-Crumley Auto Co.

All doubt as to the Flanders 20, which recently won the St. Louis-Kansas City reliability run, being a stock car has been removed. George E. Lane, local representative of the American Automobile Association, made a thorough inspection of the car last week after personally breaking the seals of the freight car in which the machine had been shipped back to Detroit, and wired Chairman Butler, of the contest board, that the car was stock in every particular.

The McCord Manufacturing Co., whose business has grown to enormous proportions since the concern's removal to Detroit, has just let contracts for a one-story brick addition to its plant on the East Grand Boulevard.

Cars assembled near the starting line in Port Jefferson awaiting their turns to participate in the events

No Records at Old Orchard

Course Was Found to Be Short

OLD ORCHARD, ME., Sept. 6—The feature of the three-day beach meet here, which closed this afternoon, was the bitter struggle for the honors in the 100-mile race between John Rutherford, in a National car, and Louis Disbrow, driving a Pope-Hartford. The former won the long grind in the fast time of 98:00 4-5, finishing 1 minute 17 1-5 seconds ahead of his rival. Had it not been necessary for Disbrow to stop during his fifty-first mile to replace a lost tire—an operation that cost him fully three minutes and a half—it is quite probable that the finish would have been of the blanket variety.

The National took the lead at the start, but in the tenth mile the Pope-Hartford swung into the lead, which it held until Disbrow came to grief in the fifty-first mile. Rutherford led from that point to the finish, although the Pope-Hartford cut a trifle off its opponent's advantage with each circuit. The time of the two contenders for each 25 miles was as follows:

Miles	25	50	75	100
National	22:36	45:12	65:35	98:00⅘
Pope-Hartford	22:15	44:28	69:38	99:18

The time would have been much faster had it not been for the incoming tide, which drove the contestants farther up on the beach, where the going was much too soft for the fast work which had characterized the earlier stages of the race.

Besides the National and the Pope-Hartford there were four other starters—Pope-Hartford, driven by C. L. Bowler; Inter-State, Harry Endicott; Buick, C. G. Jessup, and Jackson, Harry Cobe. Bowler finished third in 109:37, and Endicott fourth in 110:37, the former getting the show position despite the fact that he covered the last few miles of the race on three tires. Jessup and Cobe failed to finish.

The 25-mile free-for-all was a sop to Disbrow, however, for he nosed out Rutherford by the small margin of one second, covering the distance in 15:25. The Jessup Buick finished third, followed by Bowler's Pope-Hartford and Endicott's Inter-State.

A match race at 10 miles between an Inter-State, driven by Neilson, and a Cole 30, piloted by Habich, resulted in a win for the former in 7:56 1-5, his opponent finishing one-fifth of a second behind.

In a mile exhibition against time a Stanley Steamer, driven by L. F. N. Baldwin, negotiated the distance in 39 seconds, lowering his best previous effort by an even second. A 5-mile trial by Disbrow in his Pope-Hartford was clocked in 3:58. The summaries are in the following column.

Regarding the remarkable times made by the contesting cars, and the early claim for records which were made as a result thereof, it has developed that such claims will not stand, owing to the wrong placing of the marker designating the easterly limit of the supposed 2 1-2-mile course. The official to whom was assigned the task of placing the marker fell shy of the required distance by a considerable number of feet. Although the difference was slight it was sufficient to nullify the possibility of official recognition of any records that may have been made.

Arrangements have been made for races to be held at the beach in July of next year. Three thousand dollars in prizes has already been posted and there will be a longer and a better list of entries even than there was this year.

Automobile a Feature of Country Fairs

MORRISON, ILL., Sept. 9—That the country fairs are becoming more or less automobile shows for the farmers was shown this week at the annual Morrison Fair, the big western Illinois State fair.

In the three days there were counted from 750 to 800 visiting cars each day and the booths and tents of the various exhibitors were crowded each day with farmers and others anxious to see what the new ideas would be for the coming season.

Each exhibitor had from one to three cars on the grounds either in the open or in tents. The Buick showed three new cars, including a truck which was demonstrated to the farmers; Regal three cars, including the new underslung; Overland, Oakland, Cadillac, Reo and Ford, one car each.

One of the most interesting features of the show was the loading of the Buick regular 1,800 lb. delivery truck with 32 men, places being provided for by means of planks, and making two laps of the half-mile track in excellent time. Sales reported showed that each exhibitor was well pleased with the show and that a great many future sales would undoubtedly result from the exhibition.

Last Day's Summaries at Old Orchard

Fiat, No. 9, Hearne driver, which captured first place in the race for the Cincinnati trophy

Eddie Hearne, who piloted the winning car in the big race

Cole and Fiat Feature Fern Bank

CINCINNATI, O., Sept. 10—Cincinnati's first attempt at road races was carried through very successfully Saturday as a climax to the week's celebration of the opening of the Fern Bank dam across the Ohio River. The races were run over the Silverton-Blue Ash-Montgomery course near the town of Rossmoyne, about 15 miles out of the city. The course was a triangular one, with one very sharp turn. The length was 7.9 miles and the road none too well prepared for fast work.

Of the two races, which were run simultaneously, the big one was for a distance of 200 miles and the other was 150 miles. Eddie Hearne in the Fiat carried off the honors in the 200-mile event, winning the Cincinnati trophy at an average speed of 57.5 miles per hour. Jenkins in the Cole took second in this race and first in the 150-mile event, to which the Fiat was not eligible. Second place in the smaller race, for the Hamilton County trophy, was made by Thatcher in the Ohio.

All the cars but the Fiat, Stutz and Westcott, competed in both races, the relative position at the end of the nineteenth lap determining the standing in the 150-mile event.

Of the twelve entries for the two races all appeared at the starting point, but Mortimer Roberts in the Abbott-Detroit which held No. 1 showed up at the very last minute. The seating arrangement of the Abbott had been changed so that the mechanic was immediately behind the driver and Technical Executive F. E. Edwards refused to allow the experiment.

Things commenced to happen before all the cars had gotten away. The No. 11 Stutz, driven by Gil Anderson, had trouble in starting and after sharp work by both driver and mechanic the car had covered 20 feet in the first fifteen minutes and was withdrawn. It was found when the car was examined later that a pin or key in the transmission had caught.

Two other cars met with disaster in the first lap. The first occurred when Raimey in the Cino No. 8 threw a tire and turned over near Blue Ash. Raimey suffered a slightly sprained wrist and the car was out of the race. Then the No. 20 Colby

Westcott, No. 10, Harry Knight driver, which finished third in the 200-mile race

Jenkins, who drove the Cole to a win in the small car race and second in the big event

Cole 30, driven by Jenkins, which after winning 150-mile race, went on and captured second in the 200-mile

went out with a broken wheel, Pearce, the driver, getting slightly scratched up in the wreck.

In the fifth lap the No. 7 Cino, with Andy Burke at the wheel, who had held his position right behind Hearne and was leading in the Hamilton County trophy race, lost its brilliant chance by breaking a connecting rod. The last accident was when the Schacht, driven by Jeffkins, was wrecked in its eightieth mile. A tire blew out on the left rear wheel where the road was soft

time, finishing 11 minutes ahead of the Cole. Burke, in the Cino, followed Hearne for the first four laps when he was put out from a broken connecting rod. Jenkins, in the Cole, was in seventh place for the first two laps. Then he commenced to spurt, passing Matthews, in the Ohio, on the third lap, and Harry Knight, in the Westcott, on the fifth lap. This put him into second place for the big race and first place in the little race, which position he held to the finish. In addition to his victory

and the wheel broke. Both driver and mechanic were thrown out and Wilkie Meyers, the mechanic, received a cut on the leg.

From the beginning of the race Eddie Hearne in the big Fiat had everything his own way and was not really pushed at any

Ohio, No. 5, driven by Charles Thatcher, second in the small-car race

Jenkins had the honor of making the fastest lap of the day, negotiating the 7.9 miles in 7:13, an average speed of 65.7 miles per hour. Knight, in a Westcott, finished the first lap in the fourth place, then climbed up to third, and the accident to Burke put Knight into second place for one lap. Jenkins' spurt left Knight back in the third place until he dropped from third to sixth in the sixteenth lap, during a stop for oil, water and gasoline; then he climbed up to fourth place and the withdrawal of Thatcher, in the Ohio, put him into third place.

No. 6 Cino, with Gilchrist at the wheel, started out in the fifth place, dropped back to seventh in the third, and then was boosted to the fourth place by the withdrawal of the Schacht and the No. 7 Cino. In the sixteenth lap Gilchrist passed Knight and landed in fourth place, but was repassed by both Knight and Matthews in the next lap and finished in fifth place.

In the little race, which was decided by the position of the cars at the end of the nineteenth lap, neither the Fiat nor the Westcott was eligible, so that Jenkins, in the Cole, was leading from the fifth lap, and was closely followed by Thatcher, in the Ohio, throughout the race. Gilchrist, in the Cino, ran in third place nearly all the way. Thatcher immediately withdrew at the completion of the nineteenth lap on account of clutch trouble, declining to attempt to finish in the big race.

Scene at the start of the road races held near Cincinnati to commemorate the opening of the Fern Bank Dam across the Ohio River

The Cole came over the line a winner 5 minutes ahead of Thatcher, in the Ohio, who was 9:10 ahead of Gilchrist, in the Cino. The latter was spurting picturesquely on the last lap and was in a fair way to pass Thatcher when a tire was punctured by a spike on the road, but he finished third.

With the 150-mile race finished, the five racers continued the 50 miles still left in the 200-mile event. The Fiat was in the lead with the Cole close behind and Gilchrist in a Cino and Knight in the Westcott fighting for third place.

The race was very satisfactory from all points of view with, perhaps, two exceptions. One of these was the rather poor condition of the course, which was not well prepared for speedy work. As this was the first event of the kind it is probable that the promoters will make better road preparations for later events. The road had been well oiled, but was very soft in spots, a condition which was aggravated by the rains that occurred that morning. The policing of the track could have been very much improved upon. While there seemed to be plenty of the Ohio militia scattered around the course, there were not enough of the soldiers at the starting line, and their work in keeping the course clear during the races could have been more successful. It was necessary for the announcer on the judge's stand to notify the spectators that there was a car coming in order to awaken the militiamen to their duties. The policing of the course was a difficult affair at best, for both the electric and steam trains from the city discharged their passengers for hours during the races directly upon the side of the course in front of the grand stand, and there was no fence or other means of protection between the tracks and the race course. Not only did it require hard work on the part of the guards to keep the track reasonably clear at this point, but the trains also obstructed the view of those in the grand stand. It was only by good fortune that many of the spectators were not killed or seriously injured, as some were running across the track in an irresponsible manner at all times.

There was one feature of the race that created comment among the officials, and that was the lack of stops for repairs, or for taking on gas and oil and water at the pits. There were only five stops at the pits during the entire four hours of racing, and only two stops for tire replacements. The first car to stop at the pits was the No. 4 Ohio which halted at the end of the ninth lap after running 91 minutes to replace with a new tire the one that had been put on at another point on the course. The next to stop was the No. 9 Fiat which drew up at the end of the eighteenth lap for one minute to take on oil and tighten up the shock absorbers. The only stop in which gasoline was taken on was when the Westcott No. 10 made a three-minute stay at the pits for oil, water and gasoline in the sixteenth lap. Water was taken on by No. 3 at the end of the twenty-first lap and it got away in 1½ minutes.

The following table shows the equipment of the contesting cars in the two races:

No.	Car	Carbureter	Magneto	Tires
2	Schacht	Schebler	Mea	Michelin

Fast Time at Hamline

MINNEAPOLIS, MINN., Sept. 11—Burman enjoyed a field day at the State fair automobile racing matinee Saturday. He made the fastest mile of the afternoon, 50 seconds flat, on a far from safe and sane track and was successful in defending his possession of the Remy brassard.

Heavy rains all week had placed the track in a treacherous condition. The surface appeared to be fairly dry, but below the top coating the fine soil of the track was soft and slippery. Soon after 8 o'clock in the morning the gates were thrown open, and the police rushed every motor car coming into the grounds out upon the track. Then began a long, tiresome milling of motors around the mile loop. Harrows stirred the soft mud and the process continued until nearly noon, when gasoline tractors from the exhibits of farm machinery were called into play to pull heavy drags. The surface of the track was literally pounded down by the multiple mileage of many machines. The stretches were in fair condition by noon, but the turns never dried out.

One feature of the meet which interested the spectators was an exhibition of speed driving with a tire change, as such changes are made in the big speed events, by Ray Harroun with the Marmon Wasp. This change, the taking off of a front tire and the replacing with a new tire, was accomplished in about 50 seconds. Harroun then drove out the remaining mile, making the three miles and the tire change in a total elapsed time of 4:45.

Charley Nyquist, in a Buick, won the second event, a 5-mile race, the time being 5:44 flat. Stubborn fighting marked the 15-mile race, one of the prettiest events of the day. In this event the Staver-Chicago withdrew on account of engine trouble, leaving the Buick and two Case cars to fight it out. Each had its turn in the lead, but the tenth mile found the white Case, driven by Jaggersberger, at the head of the procession, and it held that position to the end, with the Buick second. Time, 16:25 2-5 sec.

Burman defended the Remy Brassard trophy successfully.

The final race, a five-mile handicap, free-for-all, developed some first-class handicapping. The Firestone went away first with a handicap of 50 seconds and the Cutting followed 10 seconds later. Nyquist sent his Buick away with 35 seconds lead over the scratch man and Heineman let the Case go five seconds later. Five more seconds elapsed, then the white Case car shot over the line with 25 seconds over the scratch car. The Hotchkiss was given 10 seconds to get clear of Burman and his Benz at scratch. Burman started a terrific drive and on the third mile began overhauling the others, winning by a narrow margin.

McNay brought in the Cutting second with the Case, Jaggersberger, third, Heineman fourth, Kilpatrick fifth and Nyquist sixth. Burman's time from the scratch was 4:49 3-5. Summary:

Five Miles, Class C, Non-Stock, 231 to 300 Cubic Inches

Position	Car	Driver	Time
1	Case	Jaggersberger	5:27
2	Case	Heineman	

Five Miles, Class C, Non-Stock, 301 to 450 Cubic Inches

Position	Car	Driver	Time
1	Buick	Nyquist	5:44
2	Cutting	McNay	
3	Firestone-Columbus	Sandell	

Fifteen Miles, Class E, Non-Stock, 300 Cubic Inches and Under

Position	Car	Driver	Time
1	Case	Jaggersberger	16:25 2-5
2	Buick	Nyquist	

Exhibition, Three Miles with Tire Change

Position	Car	Driver	Time
	Marmon Wasp	Ray Harroun	4:45

Five Miles, Class D, Non-Stock, Free-for-All

Position	Car	Driver	Time
1	Benz	Burman	5:06
2	Mercedes	Lee Oldfield	
3	Hotchkiss	Kilpatrick	

Exhibition Mile (Track Record: 49 2-5)

Car	Driver	First trial	Second trial
Blitzen Benz	Burman	:50 3-5	:50

Three Miles, Class D, Non-Stock, Free-for-All (Best Two in Three)
For Remy, Grand, Brassard

First Heat

Position	Car	Driver	Time
1	Benz	Burman	3:01 2-5
2	Hotchkiss	Kilpatrick	
3	Mercedes	Lee Oldfield	

Second Heat

Position	Car	Driver	Time
1	Benz	Burman	2:53
2	Mercedes	Lee Oldfield	
3	Hotchkiss	Kilpatrick	

Three Mile Exhibition Race

Position	Car	Driver	Time
1	Marmon Wasp	Ray Harroun	3:58
2	Case	Lou Heineman	

Five Mile, Class E, Free-for-All Handicap

Position	Car	Driver	Time
1	Case	Heineman (15 sec.)	5:08 4-5
2	Case	Jaggersberger (Scr.)	
3	Buick	Nyquist (15 sec.)	
4	Cutting	McNay (10 sec.)	
5	Firestone-Columbus	Sandell (30 sec.)	

Five-Mile Special Handicap, Class C, Non-Stock, 301 to 450 Cubic Inches

Position	Car	Driver	Time
1	Firestone-Columbus	Sandell (40 sec.)	5:32
2	Buick	Nyquist	
3	Cutting	McNay (40 sec.)	

Free-for-All Five Mile Handicap

Position	Car	Driver	Time
1	Benz	Burman (Scr.)	4:49 3-5
2	Cutting	McNay (40 sec.)	
3	Case	Jaggersberger (25 sec.)	
4	Case	Heineman (30 sec.)	
5	Hotchkiss	Kilpatrick (10 sec.)	
6	Buick	Nyquist (35 sec.)

Short Items of News—Boston's Two Shows

BOSTON, Sept. 9—It is a settled fact now that Boston is to have two distinct motor shows, one for pleasure cars and the other for commercial vehicles. Some time ago the Boston Commercial Motor Vehicle Association voted that it would conduct such a show, but there was some talk about a change. The sending out of the application blanks for the regular pleasure car show, however, makes it clear that there will be a second exhibition for no provision is made for commercial vehicles. The pleasure cars will be exhibited in Mechanics' Building during the week of March 2-9, 1912, this being the regular period that the Boston Automobile Dealers Association holds its show. Then the week following the Boston Commercial Motor Vehicle Association will have its exhibition. As many of the dealers are members of both associations it will be an easy matter to turn from one show to another and Chester I. Campbell, who manages the motor exhibitions here each year, will be the man in charge of both next March. For the pleasure car show the diagrams provide for about 114,000 square feet space, but that amount will not be needed for the commercial show. With no business vehicles in the pleasure section it will allow a great many more exhibitors this season. In the past a number of dealers had no chance to get in and this led to abortive attempts from time to time to hold separate shows, but they were failures. The extra week for the commercial vehicles will now allow all types of wagons and trucks to be displayed, too, which was not possible in the past. And there will be no need of an annex now even though the agencies have multiplied a great deal in Boston since the last show.

Seventeen Starters in Omaha Run

OMAHA, NEB., Sept. 11—The cars entered in the endurance run of the Omaha Motor Club for the World-Herald trophy, will leave at 6:30 A.M. to-morrow morning, on the four-day contest, intended as a dedicatory run over the newly improved North Platte route from Omaha to Colorado. The total mileage will be 656.9 miles.

The first night's stop is at Grand Island, 141.9 miles from Omaha; that on the second night being at North Platte, 168 miles farther. Returning, the cars will come back over the North Platte route to Kearney and then strike across to Hastings, the day's run being 174 miles. From here the South Platte route is followed to Omaha, going through Lincoln, the last day's run being 172.4 miles.

The following cars will start: No. 1, Lexington; No. 2, Ford; No. 3, Ford; No. 4, Ford, Glass & Evans, Grand Island; No. 5, Ford; No. 6, Velie; No. 7, Chalmers; No. 8, Kelley truck; No. 9, Case; No. 10, Maxwell; No. 11, Cartercar; No. 12, Marion; No. 14, Alco; No. 15, Paige-Detroit; No. 16, Paige-Detroit; No. 17, Lexington, and No. 18, Maxwell.

The pilot and Inter-State Auto Company official cars will be Inter-States, the Hupmobile, W. L. Huffman Auto Company, press car, a Hupmobile, and the judges' and press car, a Ford.

Ole Hibner is referee of the run, Otto P. Nestman chief observer, and George W. Coe chairman of the technical committee.

Motor Exhibits at Milwaukee Show

MILWAUKEE, WIS., Sept. 9—Milwaukee motor car, motor, parts and accessory factories were well represented at the big Industrial Exposition held in the Auditorium, Milwaukee, from September 2 to 12, under auspices of the Merchants & Manufacturers' Association in commemoration of the fifteenth anniversary of its organization. The exhibits were confined to Milwaukee-made products and it was the first time an exposition of this kind was held in Milwaukee, which now ranks as the second largest manufacturing district in the United States. The Wisconsin Motor Manufacturing Company exhibited a number of motors for trucks, pleasure cars and boats, including a six-cylinder, 50 horsepower motor, a 4-60 and a 4-45, in addition to rough and finished castings, crankshafts, etc. Other exhibitors in this line were: Davis Manufacturing Co.; Beaver Manufacturing Co. and A. O. Smith Co. The American Oxhydric Co., the Vilter Manufacturing Co. and the Western Fixture Co. exhibited welding and cutting apparatus. The Crown Commercial Car Co. was among the motor truck exhibitors. A feature of the display of The Falk Co. was a large one-cylinder kerosene engine which produced all power for lighting and working exhibits, and a number of sets of helical gear systems in operation. The Evinrude Motor Co. had a display of Evinrude motors which convert ordinary rowboats into launches or motor boats. The Milwaukee School of Engineering had a complete wireless outfit, together with a model airship, the motor of which was started and stopped by wireless nearly across the main arena of the Auditorium.

Big Garage Fire in Boston

BOSTON, Sept. 10—A big garage fire started early this morning in the quarters occupied by Kenneth A. Skinner, who does a large garage and renting business, on Clarendon street. The fire started in one of the rear garage rooms from some unknown cause and before it was put out 45 machines were destroyed or badly damaged. Mr. Skinner estimated the loss first at $150,000, but it is thought that this will be found to be too high when the cars are given a thorough inspection. He said that there were 50 machines in the building of which 40 were private cars, the rest being his renting cars. Only five machines were brought out, the fire made such rapid headway. The structure was formerly an old freight shed, and right behind it were the repair departments of several other motor concerns. It was thought that the fire would spread to these places and there was a rush to get the cars out of the buildings. In a short time the streets near the scene were filled with machines that had been run out and these also interfered with the firemen. Mr. Skinner was planning to move in a few days to the other end of the structure, to the quarters formerly occupied by the Winton company, and which had been vacated about a month. But for the fact that about 25 taxicabs which are garaged there were not due to be put up until about 3 in the morning the loss would have been far greater, as it would have been impossible to have gotten these out. Mr. Skinner said that his loss was covered by insurance, but he could not tell how many of the privately owned cars were insured.

Iowans Visit Manufacturers' Plants

DES MOINES, IOWA, Sept. 9—C. L. Herring, Des Moines and Iowa agent for the Rambler and Ford cars, this week took 60 dealers from all over the state into the Detroit and Kenosha factories of the cars which the dealers handle.

At Detroit it was said that it was the biggest delegation of dealers which had ever been there from a single state. A 50-mile trip around Detroit and a banquet were among the entertainment features there and on the return trip Mr. Herring gave the dealers a dinner at the La Salle Hotel in Chicago.

The dealers in the party were J. E. Doze, Humeston; C. W. Bopp, Hawkeye; W. A. Wells, Sully; John Jons, Boone; George W. Bilbo, Creston; James F. Buxton, Creston; O. A. Repass, Dallas Center; B. O. Bufkin, Runnells; F. Sweitzer, Hudson; E. J. Miles, Newton; Charles D. Booth, Harlan; H. J. Van Vliet, Pella; S. E. Huff, Afton; A. H. Dale, Des Moines; Edward Van Gorp, Pella; H. S. Petty, Elliott; Dale Smith, Indianola; Harris Thornton, Ankeny; Charles C. Norton, Avoca; A. C. Ware, Oakland; W. H. Fowler, Pella; A. S. Workman, Glenwood; H. J. Lytle, Ottumwa; S. Schacht, Lime Springs; T. A. Mitchell, Council Bluffs; Bert Sanford, Atlantic; D. P. Hogan, Massena; L. L. Bybee, Knoxville; G. I. Coffman, Kinross; D. N. Hunt, Osceola; L. A. Shearer, Montezuma; C. L. Seibel, Thayer; D. E. Moon, Birmingham; George De Mose, Germanville; George F. Taglander, Brighton; F. G. Hinegardner, Toledo; W. J. Courtney, Cedar Rapids; W. E. West, New Hampton; J. G. Herring, Atlantic; Lewis Scheller, Kellerton; John Connelly, Greenfield; Charles Robinson, Villisca; W. L. Morrison, Conway; C. A. Delano, Lone Tree; W. P. Brauch, Marengo; John R. Rude, Perry; Perry C. Rude, Perry; John Mace, Allerton; C. A. Bishop, Bedford; M. A. Gifford, Lewis; David Burkett, Dallas Center; J. P. Bowen, Ottumwa; A. Mickel, Walnut.

Chicago's Contest Happenings

CHICAGO, Sept. 11.—Next on the Chicago Motor Club's calendar is the commercial motor vehicle demonstration which is set for Monday, Tuesday and Wednesday of next week. This will not be a contest but a demonstration in keeping with the desires of the truck makers, consisting of out and home runs of around 60 miles a day, each truck carrying its scheduled load. The total distance to be covered in the three days will be 159 miles. If the entry list warrants it, a horse-drawn vehicle will be sent out also over the same routes in order that comparisons may be made, the horses being required to go the entire distance even if it takes a week. The entries at present number twelve, but it is thought there will be at least twenty-five start. Those in at the present time are three Clarks, two Saurers and one each of the Alco, Buick, Old Reliable, Little Giant, La Moon, and Swanson.

Already an official report on the Elgin race attendances has been made by Philip Freiler, treasurer of the Elgin Automobile Road Racing Association. According to Mr. Freiler the association collected 14,007 general admission tickets the first day and 28,002 the second, while the parking space returns show 1354 cars the first day and 2480 the second day. The association distributed $10,200 among the 75 farmers who own property around the course for their share of the receipts and on the guarantee that was made them. In addition to this the farmers received $4,500 for work which they did on the road. An interesting item was the sum of $10,500 which was spent by the Elgin association for widening, oiling and repairing the racing circuit.

Baltimore's Last Toll Gate Doomed

BALTIMORE, MD.—The old toll gate on the Reisterstown road, near the northern entrance to Druid Hill Park, the only one left in the city, is now doomed to go. At a meeting held in the City Hall last Thursday the officials of the Reisterstown Turnpike Company agreed to accept $70,000 for the portion of the roadway within the city limits.

The Ostende Meeting

The races organized by the Automobile Club of Ostende, held over the Ostende-Nieuport-Snaeskerke-Ostende circuit on September 3, were very successful. The weather was favorable and the crowd that turned out to witness the racing was amply repaid. Next year will see not only a repetition of the races, but also a competition for commercial vehicles.

Four different events were run off, the mileage covered in three of the events being 207 miles, and in the other 248.5 miles. Three of the races were won by Lion-Peugeot cars and the results were as follows:

Coupe de Liederkerke, 248½ miles; winner, Fendu; driver, Veraeren; time, 6 hours 12 minutes 55 seconds.

Coupe d'Ostende and Coupe Williams, 207 miles; winner, Lion-Peugeot; driver, Boillot; time, 3 hours 28 minutes 33 seconds (average, 60.8 miles per hour). Second, Excelsior; driver, Coosemans; time, 3 hours 55 minutes 55 seconds.

Coupe des Voiturettes, 207 miles; winner, Lion-Peugeot; driver, Goux; time, 3 hours 52 minutes 38 seconds.

Memos From All Points—Latest Contest News

DENVER, COL., Sept. 11—The second annual Chalmers Owners' Consistency tour will be run on September 14 and 15, 1911, starting from the McDuffee Motor Company's salesrooms, 1517 Tremont Place, at 8.30 A.M. The management has taken great pains to provide everything necessary for the participants in the tour and ladies are especially invited to compete for the Chalmers trophy. The contest is not one of speed but of efficient car management.

SYRACUSE, N. Y., Sept. 9—Motorists of Syracuse and Central and Northern New York are on the *qui vive* for the most pretentious race card ever offered locally, scheduled for Saturday, Sept. 16, the closing day of the New York State Fair, upon one of the fastest mile circular courses in the country and with President Taft as the guest of honor. Vice-President Sherman will also probably be here. Burman, in the Blitzen-Benz, will be one of a famous list of visiting drivers. He will endeavor to lower his mile world's record of 48.72 seconds on a circular track. Burman figures his opportunity is here, since drivers regard the Syracuse track as the fastest mile dirt track in the country.

GREENSBORO, N. C., Sept. 9—The Greensboro Automobile Club has just been organized with a membership of 35—and good prospects for 100 or more. The officers are as follows: C. M. Van Story, president; Dr. J. T. J. Battle, vice-president; M. W. Thompson, secretary, and R. C. Bernau, treasurer.

The main object of the club is the promotion of good roads. The Glidden Tour is expected to pass through this city. If the schedule makes this city a night stop, the cars will be housed in the Auditorium. The county (Guilford), it will be remembered, captured the Good Roads prize of $1,000 in November, 1909, offered by the *Atlanta Journal* and N. Y. *Herald*.

MILWAUKEE, WIS., Sept. 9—The Milwaukee Automobile Club entertained 560 orphans, the largest number since it inaugurated an Annual Orphans' Outing day, on September 7, more than 100 touring cars being donated by members to carry the little unfortunates from the asylums to Washington Park, where a lunch was served on the grass. Frederick Gettelman was chairman of the outing committee and W. H. Pipkorn, through whose efforts the outings were first arranged and continued, acted as chief marshal. The supplies were transported in three trucks, a Stegeman, a White and a Pierce-Arrow. Mrs. Gustav G. Pabst, wife of the president of the Pabst Brewing Company, donated all ice cream and cakes, as has been her custom in past years.

Indianapolis Abandons Grade Crossings

INDIANAPOLIS, IND., Sept. 11—This city within the next few weeks will begin the abolition of all railroad crossings at grade in the central part of the city. It is the intention to let contracts for the entire work at one time, and it is believed that within three years all grade crossings in the center of the city will be eliminated, leaving grade crossings only on the outskirts.

Henry W. Klausmann, city engineer, is now engaged in preparing plans for the work, which, it is estimated, will cost approximately $6,000,000, and work will start by January 1.

Under the law the railroad companies must pay 75 per cent., the city 16 per cent. and the county and street railroad company the remainder. At the last session of the Legislature the city was authorized to levy a special tax of 6 cents on each $100.

Rain Kills Hartford Races

Rain and bad weather at Hartford, Friday night, caused the abandonment of the race meeting that was scheduled to be held at Charter Oak park on the final day of the Connecticut State fair. Quite a program of races had been arranged with a number of local entries.

S.A.E. Prepares for Active Winter

FOR the first time in its history the S. A. E. is planning a foreign trip. Indications point to a possible participation in the trip of about 100.

The members of the S. A. E. will leave this side of the water for England about November 1st. The first few days in England will be spent in examining the exhibits of the automobile show which will then be in progress at Olympia, London. The visiting engineers will be entertained by the Incorporated Institution of Automobile Engineers, which is the English Society corresponding to the Society of Automobile Engineers.

A trip will be made to Birmingham to see the factories of the Austin Motor Company and the Wolseley Motor Car Company as well as to Coventry to go through the plant of the Daimler Motor Company.

A run through some of the interesting country in the Warwickshire district, Stratford-on-Avon, and surrounding territory, has been arranged.

The Humber automobile factory, one of the largest in England, will also be visited.

It is planned to devote an evening to joint technical discussion by members of the Institution of Automobile Engineers and the Society of Automobile Engineers.

The S. A. E. members will be shown around the garages of one of the big London cab companies, and perhaps the plant of the London General Omnibus Company.

The party of engineers will probably go also to Newcastle-on-Tyne to see the Armstrong-Whitworth factory.

The Brooklands track will be visited, some racing cars being brought specially for the occasion.

The American motor car designers and producers will make a short trip to France to see some automobile factories there.

Autumn and winter schedules of meetings of the Society of Automobile Engineers have been announced. At a meeting of the society council held last week it was decided that the annual meeting of the society shall be held in New York City, January 18, 19 and 20. This is during the commercial vehicle division of the automobile show at Madison Square Garden. Scientific papers will be presented and discussed, as well as reports of the standards committees; and officers for the ensuing year will be elected.

The Philadelphia branch of the society held a meeting at the Engineers' Club in Philadelphia, September 13.

On September 28 the Metropolitan section of the S. A. E., in its session at 1451 Broadway, New York City, will discuss slide, rotary and piston versus poppet valves for gas engine service, and novelties in valve construction. Also brake-horsepower developed by automobile motors of various current sizes.

The next meeting of the Detroit section of the S. A. E. will be held in Detroit on Thursday, October 5.

First of the committee meetings ordered at the Dayton convention of the Society of Automobile Engineers, with reference to the Iron and Steel Division of the Standards Committee, was held recently at the headquarters of the organization at Broadway and Forty-first street.

This division has been in the habit of making semi-annual reports incorporating specifications for plain and alloyed steels and irons used in automobile manufacture, but at the Dayton general meeting it was determined to instruct the committee to take some furher action than was incorporated in its accepted report.

The chief matter under discussion was as to whether chemical specifications or appropriate physical qualities should be the rule in ordering steel. Whether the buyer should specify the constituent alloys to enter into the manufacture of the steel ordered or whether he should state the purpose for which the steel was to be used and specify that it must have certain physical qualities rather than a fixed chemical composition.

The steel men insist that if a buyer specifies a certain chemical composition he should not incorporate into his order that the steel shall have certain qualities or vice versa. The position of the Iron and Steel division is that the chemical formula has the most apparent advantages.

At the recent meeting of the division the following were present: Henry Souther, Consulting Engineer, Chairman; W. P. Barba (Midvale Steel Company); E. L. French (Crucible Steel Company of America); F. W. Trabold (J. H. Williams & Company); Howard E. Coffin (Hudson Motor Car Company); M. T. Lothrop (Halcomb Steel Company); George L. Norris (American Vanadium Company); H. B. Bent (Pennsylvania Steel Company); S. V. Hunnings (American Locomotive Company); Joseph Schaeffers; A. R. Gormully (United States Motor Company); Thomas Towne (Union Drawn Steel Company; New York State Steel Company); Coker F. Clarkson, Secretary.

Glidden Pathfinder En Route South

With the start of the Pathfinding Flanders car from this city on the afternoon of Friday, September 8, the Glidden Tour took on a new air of importance. The car has since then been making good headway and on Monday had reached Roanoke, Va., on the trip. Two days will be spent at Atlanta, Ga., and Jacksonville, the objective point of the trip, should be reached September 19.

The first day's trip was to Philadelphia; Saturday night Gettysburg was reached; Sunday night the car had reached Staunton, and next day it was in Roanoke. The roads to Philadelphia are good, the only trouble being the necessity of procuring Jersey licenses. Between Philadelphia and Gettysburg the chief difficulty will be in the toll-gate charges, $4.75 being the maximum amount for a single car between these cities. The roads from Philadelphia to Gettysburg are excellent with the exception of the last 10 miles, which is a worn-out pike. From Gettysburg to Winston-Salem, N. C., the roads are also good.

Owing to the change of the dates of the tour and its conflict with the 1600-mile Reliability Run of the Chicago Motor Club it was impossible for David Beecroft, the referee officially selected to officiate, and P. J. Walker, member of the Contest Board, San Francisco, Cal., has accepted the position of referee.

To date 40 entries have been received. Of these 11 are factory entries, made up as follows: Maxwell, three cars; Flanders, three; Metz, three; Halladay, one; and McIntyre, one. The remainder of the entries are private owners who live in Atlanta, Ga., Jacksonville, Fla., and other Southern cities. Entries close October 1.

Chicago Dealers' Open-House Week

CHICAGO, Sept. 11.—The Chicago Automobile Trade Association has decided definitely to stage its fall opening from September 30 to October 7 inclusive, a period of eight days, in which time the dealers will keep open house, displaying their 1912 models and decorating the row. It is planned to illuminate the street at night by means of strings of incandescents and each dealer is supposed to keep open evenings. Plans for financing the show call for assessing each dealer according to his frontage, the car dealers occupying the first floor paying $2 a foot, with a minimum charge of $5. Those on side streets are to pay 75 cents a foot. This, it is thought, will raise a fund that will enable Chicago to make a proper display.

Peeps Thro' Goggles at Distant Lands

What the Foreigners Are Doing in Automobiling

Items of interest, gathered here and there in foreign countries, having special reference to the activities of motorists. Motoring in Italy; Irish improving roads; Canadian touring; Scotch oppose radical legislation; unique joy-ride case; English medicos take to the automobile.

MOTORING in Italy affords some of the most enjoyable moments of the automobilist's series of tours. This is particularly the case when the route includes Florence; Urbino, the city of Raphael; Bramante and the gorgeous Frederico di Montefeltro; Perugia and Orvieto in Siena; lovely Montepulciano; Volterra, and other small hill towns of Tuscany and Umbria.

The Irish Roads Improvement Section of the Automobile Association and Motor Club is doing an amount of work that is winning praise from the country people. The section's work includes the advancement of reforms in the methods of constructing and maintaining the roads. Incidentally, the section is making a persistent effort to mitigate the very bad habit of patching roads with metal of unseemly proportions.

There are now several hundred automobilists in the Island of Java, about 500 machines having been imported into the Island in 1910. The Java Motor Club has the credit for accomplishing splendid work in the matter of establishing petrol depots in several sections of the Island.

There is not a finer drive in all of Canada than the roads found in Nanitoulin Island, which lies at the head of the Georgian Bay. These highways stretch over hundreds of miles. And yet there is not a single automobile on the island, nor is there a tram car line or a railway. But it is timely to say that the denizens of the island are by no means happy over the existing conditions of transit, as they lose days in travel while on business errands, horse-drawn vehicles being the only accommodation afforded. These people are seeking a means by which automobiles may be introduced into the island. Nearly all of the goods consumed are supplied by commercial travelers who wend their weary way over the island. There is a field there for passenger and freight motor cars, even though the market is limited.

Simcoe, Grey and Bruce Counties in Owen Sound are the fortunate possessors of splendid roads. A certain cement quality in the gravel and stone makes the highways quite equal to macadamized roads. Although there are but six motor cars in Owen Sound owned by private individuals, and one automobile for public hire, scores of touring parties head for Georgian Bay Summer resorts during the season and a great many automobiles are to be seen. One touring party made the distance of 162 miles from Niagara Falls to Owen Sound within the space of seven hours. They reported the roads as being in excellent condition, and as improving until they reach the bay. There are 200,000 inhabitants residing in the Owen Sound district, the towns including Markdale, Derham, Harriston, Hanover, Chesley, Southampton, Wiarton, Meadford and Collingwood. A big opening exists in that section of the country for passenger and freight automobile service, the towns now being wholly dependent upon teams to supply the local traffic. Owen Sound finds it impossible to take care of its trade without the aid of automobiles, for business men are chronically behind in their deliveries in spite of the fact that eighteen livery establishments are maintained there. The only months that the snow proves a serious impediment are from January to April. The remaining nine months of the year are favorable to automobile service. The people of the country are beginning to ask if it is not wiser to adopt motor cars for passenger and freight service than it is to depend upon the two lame railway lines which are now in commission.

It has been decided to hold the next International Automobile Show in Berlin, from the 12th to the 22d of October. This will be the first exhibition of the kind given in Berlin since 1908.

Scotland is taking good care that her East and West Coast automobile routes are being admirably patrolled. Men are employed on duty continuously. Handbooks are published enumerating the location of all patrols, as well as the address of the nearest road-agent, in case repair parts are required by automobilists using the road.

The Legal and Legislative Committee of the Scottish Automobile Club declares the association opposed to the Motor Traffic Street Noises Bill recently introduced locally. The committee base their antagonism on the ground that automobile owners would be put to great inconvenience were they to comply with one of the most signal provisions of the bill, namely, that compelling a uniform type of horns to be used.

The miraculous growth of the Royal Automobile Club of London is a subject of general discussion throughout Europe. Applications for membership reached 1,483 in number during July.

A case in London recently came to trial where a chauffeur had taken out his employer's automobile for the purpose of indulging in a "joy ride"—the term was used in the Magistrate's court. At the end of the day in question the employer discovered that the chauffeur had used up an amount of gasoline sufficient to run the car one hundred miles. Determined that he would make an example of his driver, the employer caused him to be arrested on a charge of larceny of the gasoline. When the case came up in the police court the chauffeur was given the choice of being dealt with summarily or going for trial at the Sessions. The chauffeur took advantage of the latter prerogative. Without hearing any statement of the important points involved or listening to a hearing by the Court, the Grand Jury threw out the bill and the chauffeur went free. But this was not all. The Presiding Judge in endorsing the action of the Grand Jury compared the chauffeur's act of appropriating the gasoline with that of a groom feeding his employer's horse with his employer's oats, thereby exonerating the chauffeur.

English medical practitioners have gone in for automobiles to a great extent within the last twelve months. But in order that they may ascertain if the motor car is an economical factor compared with the old horse-drawn shay these doctors have indulged in some demonstrations. They have found out that the average cost of operating a 15-horsepower machine is but a little more than one cent per mile in excess of running a 6 to 8-horsepower motor car. They proved that the expense of operating a 20-horsepower machine is less than two cents a mile in excess of the average cost of running a small, single-cylinder vehicle. The average fuel consumption of a 15-horsepower machine proved to be one gallon for twenty miles, the same measure supplying a 25-horsepower car for a distance of seventeen miles. The doctors say these figures are less than the expense of keeping a horse.

From Springs to Hard Coal Mines

An Ideal Autumn Tour for Novelty Seekers

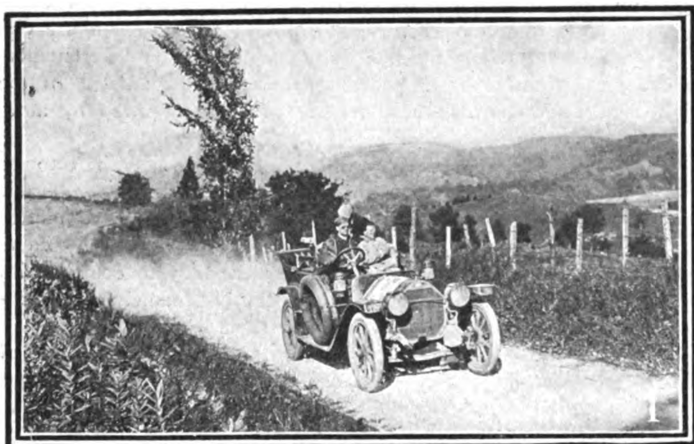
How the automobilist may spend a few days in a rather unusual tour from the splendid resorts of New York and New England to the Anthracite region of Pennsylvania with all its richness and squalor and its foreign appearance and interesting details. The trip as scheduled is for three days' running time, but it should take four and ought not to be condensed into two.

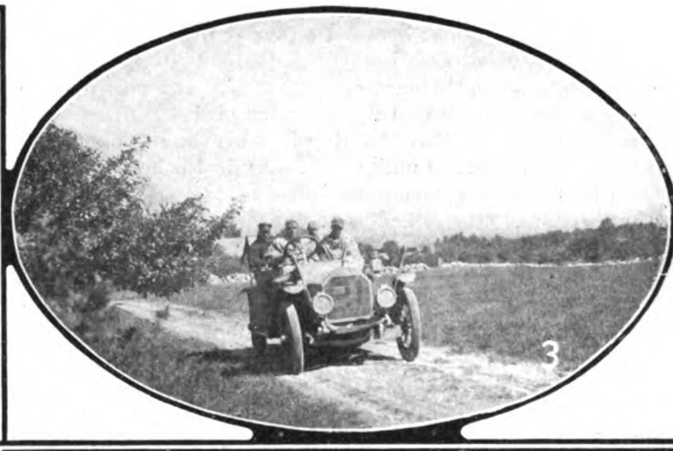
THERE is a constant demand from motor tourists who are spending the early Autumn in the New York hill counties or at the New England resorts for something in the line of diversion. To such an automobile tour from, say, Saratoga through Southern New York into Pennsylvania, and a swing around through the mountains of that State may serve the purpose of affording a little variety to the vacation.

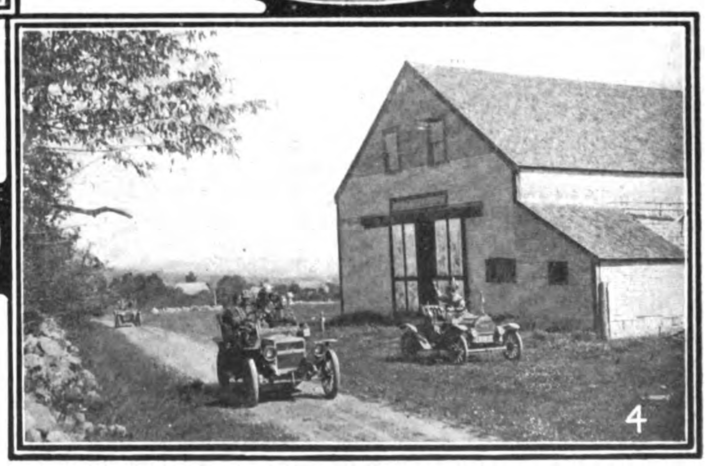
There are numerous routes that may be followed, but the pleasure of such a tour is measured largely by the absence of difficulties to be encountered, and good roads and adequate hotel accommodations are among the things most devoutly to be desired. As the routes selected for the purposes of this article have been mapped out by the *Automobile Blue Book* and indorsed by the Touring Club of America it may be assumed that the tour will be over the best roads afforded by the sections traversed.

Starting from Saratoga the party will find an excellent route as far as Amsterdam in Route 229 of Volume 1 of the current issue of the *Blue Book*. Ballston is the first town of any size to be met. The first five miles is over excellent macadam which leads into a good dirt road two miles before reaching Ballston.

The country through which this part of the route goes is strikingly beautiful and varied in its scenic setting and will be long remembered as a beautiful picture. Charlton, a small hamlet, is about eight miles farther along, and shortly after passing the village one of the worst stretches of road on the trip will be found. This, however, is not long, and after it is passed the roads will be found to be excellent except for some rather trying water-breakers after passing Glenville. From there to Amsterdam the road is macadamized and is in fine condition. The mileage to Amsterdam is 28.9.







1—Riding over millions of tons of anthracite
2—Beginning the climb from Binghamton to Wilkes-Barre

3—A typical country lane in Central New York
4—Approaching the Susquehanna River near Harrisburg

At this point a change to Route 77 is advisable in order to travel for a distance on the main truck road up the Mohawk Valley to Herkimer. The roads out of Amsterdam are finely improved and the way passes Aiken Station, Fonda, Yost's Station, Palatine Bridge, St. Johnsville and Little Falls before reaching Herkimer. This is 49.6 miles from Amsterdam, practically all of which is over improved roads. A left turn is made at Herkimer and a short run brings the party to Cooperstown.

From Cooperstown to Oneonta the proper route to follow is Route 289A, passing through Milford, Portlandville, Milford Center to Oneonta, a mileage of 12.4, making a total mileage for the tour so far of 96 miles. If the start from Saratoga has been early, this is a good place for the midday meal and rest, for there are several excellent places of refreshment for the members of the party and the car at Oneonta.

The first hour of the morning trip will be found to be the hardest and at the same time the pleasantest of the run, but every minute will be enjoyed.

The afternoon start may be delayed until 3 o'clock if desired, because the rest of the day's run into Binghamton is only 61.4 miles by Route 301. This takes the party down the valley of the upper reaches of the Susquehanna River and through a delightful Summer resort region. The chief places to be passed are Otego, Wellsbridge Station, where the Susquehanna is crossed, Unadilla, a noted resort, Bainbridge, Afton, Nineveh, Harpursville, Belden, Sanitaria Springs and Port Crane into Binghamton.

The roads are generally good and there should be no difficulty in reaching the objective point of the day's run by 6 o'clock. Binghamton has a number of creditable places of entertainment.

The second day's run will give the party a taste of hill climbing into the heart of the richest anthracite country in the world which lies between Wilkes-Barre and Scranton, Pa., high in the Alleghanies. It is almost like a trip to Poland or Hungary to traverse the coal mining towns of this section. Plain English is understood only by the children and a few adults and the character of some of the places is very similar to that of villages under the flag of Kaiser Wilhelm and the Emperor Franz Josef, to say nothing of Czar Nicholas. The streets in these villages are narrow and crowded with children, something like the East Side of New York City.

Out from Binghamton the way leads upward via Route 361R of Volume 3 of the *Blue Book*. This route passes through Kirkwood, N. Y., and crossing the Pennsylvania State line touches Great Bend, New Milford, Harford, Glenwood, Fleetville, Wallsville, Waverley, Clark's Green, Clark's Summit and Providence into Scranton. This is 59.3 miles from Binghamton and has some heavy hills and a few rough spots in the roads, which are not sufficiently long to be annoying.

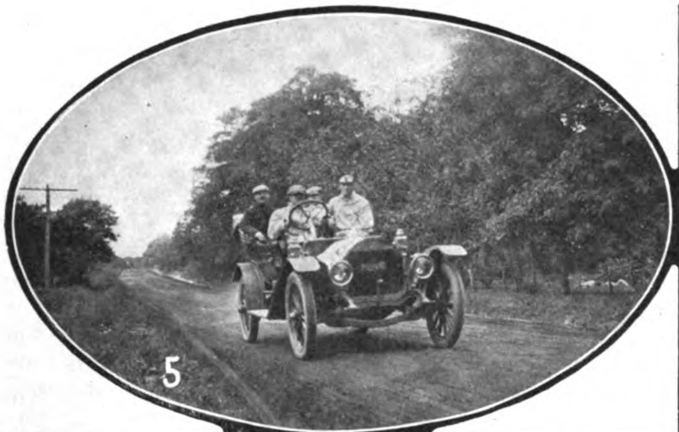
From Scranton to Wilkes-Barre is 17.8 miles via Route 365 of the same volume. This is the hard-coal region proper and there is nothing like it on earth. The millions of tons of anthracite that have been mined and used in the past constitute only a fraction of the wealth that still lies below the surface of the blue hills awaiting the call of the miner to serve a useful purpose in the advancement and comfort of humanity.

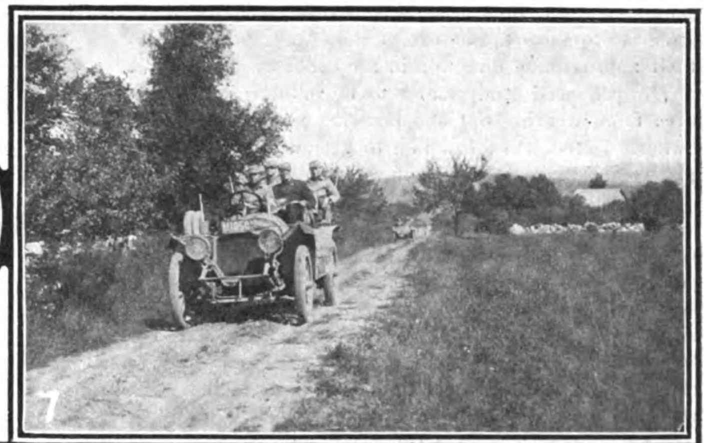
The road touches Hyde Park, Taylor, Old Forge Station, Duryea, Pittston Junction Station, Pittston, where a good macadam road is picked up into Wilkes-Barre.

Considerable time ought to be devoted to this day's run as the grades are pretty stiff in spots and the roads are not marvels of construction. Then, too, a leisurely inspection of the anthracite region will repay all the time spent upon it. Besides these things, some of the scenery along the way rivals anything in the eastern part of the United States in rugged beauty and sylvan richness.

The third day of the trip is to Harrisburg, the capital of Pennsylvania, and, via Route 391, this is 108.8 miles through the heart of the Alleghany Mountains. It follows the valley of the Susquehanna River to Bloomsburg, Danville, Northumberland, Shamokin Dam, Port Trevorton to Harrisburg.

From Harrisburg the tourists may pursue any of a dozen different directions and can return by varied routes.





5—A fine bit of road near Oneonta, N. Y.
6—In the heart of the anthracite region

7—Before meeting the State road into Binghamton
8—A Glimpse of the Susquehanna near Wilkes-Barre

Stresses and Strains in Tires

Part I.

Translation of an article by Henri Petit, in La Technique Automobile et Aérienne

THE duty that the pneumatic tire—the connecting link between the car and the ground—has to perform, is very complex. So complex is it that no one has yet been able to completely analyze it, at any rate not sufficiently in order to be able to reconstruct an integral synthesis from the resultant analysis so as to evolve the elastic wheel.

It is possible to state affirmatively that the moment that anyone has discovered the exact manner in which the pneumatic cushion of an automobile wheel works, then the problem of the elastic or resilient wheel will be three parts solved.

It is not the intention here to solve the complex rôle of the pneumatic; the object of this article is more modest. It is proposed to show the nature of the efforts supported by the tires, their approximate direction in the order of sizes.

The proposed study about to be indulged in will not prevent tires from wearing out and bursting to the great despair of the owner. But it will allow him to get an insight into the different phases and multiple causes of wear and premature destruction.

The chauffeur will be able to see where his personal co-efficient comes in, and consequently be in a better position to give the tires all the cares that are dependent upon him in order to prolong their useful existence.

It is proposed to classify the efforts to which the tire is submitted in static efforts (these are the efforts that act upon the tire when the car is standing still) and dynamic efforts, that is to say, efforts that are caused by the diverse movements of the car.

Static Efforts

It is presumed that the reader knows how a pneumatic tire is made, and in the following article it will be presumed that the inflated tire presents geometrically the exact form of a tore.* This hypothesis is as near to the truth as it is possible to go and in every case the errors that may be made in adopting it are much less than approximation that we hope to attain.

It will be remembered that R is the mean radius of the tore, r the radius of the meridian circle. The dimensions by which tires are usually denoted are expressed by

$2(R+r)$ (diameter of the parallel equator)

and

$2r$ (diameter of the meridian).

Supposing p to represent the difference in pressures (expressed in kilog per square centimeter) between the air enclosed in the inner tube and the atmospheric air.

The figure p will be the reading on a manometer or pressure gauge applied to the valve.

p_o will denote the initial pressure to which the tire was inflated, or to be more exact we will call p_o the value that p will take when *the tire is not opposed to any exterior effort*, the temperature of the air inside being the same as the exterior air at the moment of inflation.

p_o will therefore be the theoretical pressure indicated by the makers, which are given as a guide for inflating tires.

Finally we will admit for the calculations of tensions supported by the canvas, that

1. That the tire is perfectly souple.
2. That the canvas does the work, the rubber of the inner tube and outer cover not supporting any effort.
3. That the canvas known as straight grain included in the arc are not affected by the effort due to the internal pressure.

Superficial Tension

One knows that an elastic membrane separating two gaseous masses, the pressures of which are different, supports an effort of traction which is a component of the differences in pressure and of the curvature of the membrane.

If the radii of the principal curvatures are designated by r' and R' at any point of the inflated tire the surface tension will have a value at this point

$$A = \frac{P}{\frac{1}{R} + \frac{1}{r}}$$

It is interesting to note the variations of the radii of the principal curvature of the tore at the different points of the surface.

The minimum radius r' is evidently equal to the constant value of the meridian circle.

$$r' = r$$

The radius R maximum will vary according to the different points of a given meridian.

It will be as well to give it a positive value (in the same manner as r') when the curvature will have its concavity turned toward the interior. Taking Fig. 1 as an example denoting a meridian section of the tore.

At the point A we have

$$R' = R + r$$

Considering the displacement from A to B the curvature diminishes until it becomes nil at B. R' will grow indefinitely from A to B while remaining positive.

In displacing from B to C the curvature becomes negative and augments the absolute value. The radius of the curvature varies from *O* to $-(R-r)$

The surface tension A varies therefore between the two values

$$-\frac{p}{\frac{1}{r} - \frac{1}{R-r}}$$

and

$$+\frac{p}{\frac{1}{r} + \frac{1}{R+r}}$$

It is easy to see that the maximum will be at the point C. In fact the denominator is maximum when R' is negative and equal to $R-r$.

The maximum surface tension is therefore

$$A_M = \frac{p}{\frac{1}{r} - \frac{1}{R-r}}$$

$$= p\frac{r(R-r)}{R-2r}$$

It will be interesting to see how this compares with different

*A surface described by a conical section, a circle rotating about a straight line in its own plane. A solid of revolution inclosed in such a surface sometimes called anchor ring or simply ring.—*Webster.*

sizes of tires. First of all it should be noted that R is always much greater than r. We have therefore for the current dimensions of tires of cars the following:

For casings:

700×90	$R = 30.5$ cm.	$r = 4.5$	$\frac{R}{r} =$ about 7
790×90	$R = 38.5$ cm.	$r = 4.5$	$\frac{R}{r} =$ " 7.5
990×90	$R = 41$ cm.	$r = 4.5$	$\frac{R}{r} =$ " 9
820×120	$R = 35$ cm.	$r = 6$	$\frac{R}{r} =$ " 6
920×120	$R = 40$ cm.	$r = 6$	$\frac{R}{r} =$ " 6.8
895×135	$R = 38$ cm.	$r = 6.8$	$\frac{R}{r} =$ " 5.5
935×135	$R = 40$ cm.	$r = 6.8$	$\frac{R}{r} =$ " 6

The pressure p to which tires should be inflated varies, as everyone knows, with the diameter of the tire. That is why tires of 90 millimeter section should be inflated to 5 kilogrammes, 120 m.m. section to 6 kilos and 135 m.m. sections to 7 kilos.

It is easy to see how far the same section and also for the same pressure the maximum surface tension will vary.

It is expressed by

$$A_M = p\,r\,\frac{R - r}{R - 2r}$$

$$A_M = p\,r\,\frac{\frac{R}{r} - 1}{\frac{R}{r} - 2}$$

For the same section the product $p\ r$ is constant.

The fraction

$$\frac{\frac{R}{r} - 1}{\frac{R}{r} - 2}$$

is greater than unity, and will decrease when $\frac{R}{r}$ increases. From which it is possible to draw the following conclusion:

The surface tension is proportionately smaller for a given section of the tire as the diameter of the wheel increases.

If we consider the various sections of casings we can find out that the surface tension is proportionately greater as the tire increases in size.

In fact, in the product

$$A = p\,r\,\frac{\frac{R}{r} - 1}{\frac{R}{r} - 2}$$

the term p will increase when r increases.

This table will show that $\frac{R}{r}$ diminishes when r increases.

The three factors p, r, $\frac{\frac{R}{r} - 1}{\frac{R}{r} - 2}$ will increase with r.

That is why a 700×90 tire will have a superficial maximum tension:

$$A_M = 5 \times 4.5\,\frac{7 - 1}{7 - 2} = 27 \text{ kilogrammes.}$$

A_N 875×135

$$A_N = 7 \times 6.9\,\frac{5.5 - 1}{5.5 - 2} = 61 \text{ kilogrammes.}$$

It is for this reason that tire makers manufacture the tires with a proportionately greater number of layers of canvas as the diameter increases.

Ninety millimeter section tires usually have 4 layers of canvas, while 135 m.m. sections have 7 layers of canvas.

The proportion indicated by the calculation does not seem to have been followed. This is accounted for by the fact that in all tires efforts independent of the diameter must be taken into consideration, which will be explained later. So that if the number of layers of canvas to be used is denoted by n and a the tension to support each one of them, n must be calculated from the formula

$$n = \frac{A}{a}$$

which would seem rational if the surface tension were not taken into consideration, but it must be calculated from the following:

$$n = n_0 + \frac{A}{a}$$

(To be continued)

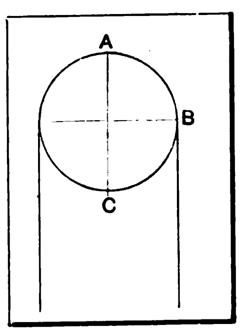


Fig. 1—Diagram denoting the meridian section of the tore

Harking Back a Decade

THE American Bicycle Company is preparing to move its headquarters for motor vehicles from Toledo, Ohio, to New York City.

The Crestmobile, long since relegated to the lumber room of the past, comes into the limelight by virtue of an announcement that, owing to costly improvements incorporated in the new model, \$50 had been added to its selling price of \$500.

The New York-Buffalo endurance test, with its seventy-seven entries, of which twenty-six were steamers, occupies not a little space in the secular and trade press.

Commercial vehicles are doing stunts, as is evidenced by an account of a Locomobile delivery wagon climbing Nelson's Hill (north of Peekskill) without a stop, despite its 800-pound load.

Editorials have much to say regarding the stopping of the Newport races, the general tone of the comment being hostile to the motorists and favorable to those who succeeded in spoiling the proposed sport.

This week ten years ago a party of tourists from the Chicago Automobile Club were on the road en route to the Pan-American Exposition at Buffalo.

A writer in *The Motor Review* of August 12, 1901, deprecates the practice of crossing the spokes in the effort to attain rigidity in wire wheels, such procedure, in his opinion, hastening the disintegration of the wheel.

The Upkeep of the Car

When the Owner Is His Own Repairman

The automobile enthusiast derives a large proportion of his enjoyment from a thorough acquaintance with every part of his automobile. This knowledge is only picked up by doing the repair work which lies within the scope of the garage, whether it be upon the motor, chassis or body of the automobile.

FOR the automobile enthusiast who lives out of town, or in such a location that he is able to have his own private garage, nothing furnishes such a great diversion as attending to the needs of his car. In the same manner as the average amateur photographer finds half his enjoyment in the making of his own pictures, so does the average automobilist, who has entered the game for the love of it, find his greatest pleasure in the knowledge that he knows his car from spark plugs to tires. He will know the meaning of the slightest sound which is distinct from the ordinary rhythm of the engine.

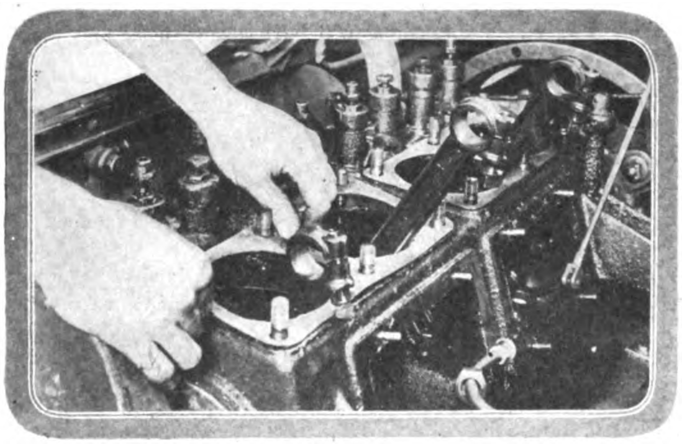

Fig. 1—Illustrating method of fitting gasket between cylinder and crankcase castings

The garage will gradually accumulate the necessary tools as each job comes up until about the time that the second car is due to arrive, it will generally be found that Mr. Owner has his well-defined notions as to what kind of tools he wants and where he wants them kept. The character of the work turned out by the proprietor of the garage may be very closely determined before the work is completed by a casual inspection of the manner of keeping the tools. If the gasoline torch is found to be kicked into the farthest corner of the building because it did not happen to be needed in the last piece of work which was performed at the bench, an entirely accurate and correct idea of the manner in which the repair was carried out may be formed.

After the manner in which the garage is kept comes the despatch and neatness with which the actual work is done. It is assumed that the automobilist has some slight leaning toward things mechanical or he would have given up the attempt to be his own repairman a very short time after he first conceived the idea. Note the manner in which an experienced workman will go about making a repair. For one thing, there will be no lost motion. Lost motion is lost efficiency in any machine, whether the piece of mechanism be a man or an engine. There will be no misguided haste, but a continuous march toward the completion of the work.

A few customary repairs which may be easily carried out in even the most meagerly equipped repair shop are here taken up and described by way of illustrating the correct method of procedure as compared with that in which the inexperienced man would go about the same work. A gasket is to be fitted, for example, between the cylinder block casting and the crankcase. The leakage between these two castings has been detected by a wheezing sound, and then on inspection the driver notices signs of oil having leaked through the joint. It is decided to replace the gasket, so the bolts which hold the cylinders in place are removed and the castings pried apart by means of a fine chisel lightly tapped upon with a mallet. This will disclose the crankcase after the cylinder castings have been lifted clear of the pistons and the same allowed, along with the connecting rods attached to them, to rest gently against the edge of the casting. The pistons are then removed from the connecting rods, leaving them in the position shown in Fig. 1. The method of removal will depend entirely on the manner in which the wrist pins are fitted. If it is easier to remove the caps of the connecting rods from the crank end, this may be done and the rods lifted out of the crankcase.

The old gasket is then thoroughly removed. This has to be done carefully by means of a scraper, as it will be found that the old one will adhere very closely to the metal surface and it will require the application of considerable force and a like amount of the proverbial elbow grease before this part of the work can be declared finished. The surface of the metal is then filed until it is entirely clean and bright when it is ready to receive the new gasket. If the cylinders are cast in pairs the

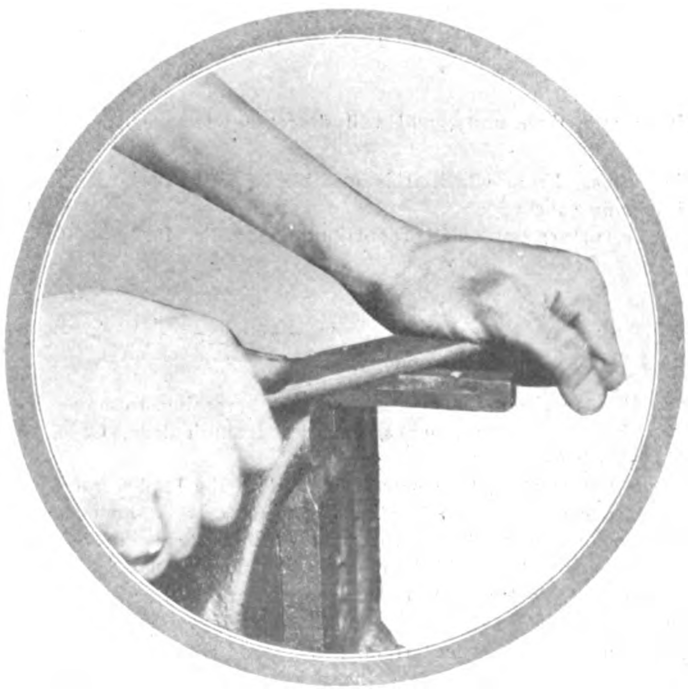

Fig. 2—Illustrating the method of filing the burr from clutch key

gasket is better when made in two pieces for a four-cylinder motor, as shown in the illustration. In other words, each block of cylinders should have a separate gasket. The new gasket will be bought accordingly in pieces, which are large enough to cover the parts to be fitted. It is first cut to the approximate size and allowed to rest upon the bolts which project as shown. The hammer is then called into service and a few light blows are dealt the material above each bolt until an impression has been made which will accurately determine the relative position of each. During this time the gasket is not allowed to shift its position. It is then removed and the holes for the bolts are cut in the positions shown by the marks which were impressed during the hammering. A slight allowance in size is made in the hole so that it will clear the bolt all around, thus taking up any inaccuracy there may be in centering.

After the holes for the bolts are cut in the gasket material it is slipped down over them until it fits flush against the surface of the metal to which it is to be fitted. It is at this point that the novice is often puzzled. Two holes have to be accurately cut, which will be of the same diameter as the cylinder and accurately centered in relation to the bolt holes. The amateur will often betray himself by starting to work with a rule and compasses. This, however, is not necessary; the correct and shortest method of procedure is to use the same method as that employed in cutting the bolt holes, that is, by means of the hammer. The gasket is tapped gently around the edge of the circle and around the outside where it is to be cut when finished; when removed it will be seen that the bounding edges of the gasket will be clearly defined and that the actual cutting will be easy.

In fitting keys the matter of experience again enters into the question to a large extent. Fig. 2 illustrates the act of removing the burr from a clutch key which was taken from the clutch as shown in Fig. 3. In removing irregularities from metal care should be taken that a bad fit does not result due to having filed away material in such a manner that the part no longer fits tightly. This is especially so in the case of a key held in the manner illustrated in Fig. 4. The other key shown above is fitted with two pins which keep it in the correct relative position. In fitting the key shown in Fig. 4, if it is desired to have the gears placed upon the shaft in a certain relative position, the shaft may be set in the vise as shown. The gears are then slipped over the shaft, the key inserted and hammered into place.

Besides the repairs mentioned there are numerous others which will present themselves from time to time embracing every part of the motor, chassis and even the body of the car, until the owner will become so thoroughly acquainted with the various parts that, except in case of unlooked-for accidents, the matter of upkeep will resolve itself into a mere matter of schedule. Parts will need replacement from time to time on the best of cars, but with the care which a man who likes the work will give his own car the life of every part may be prolonged.

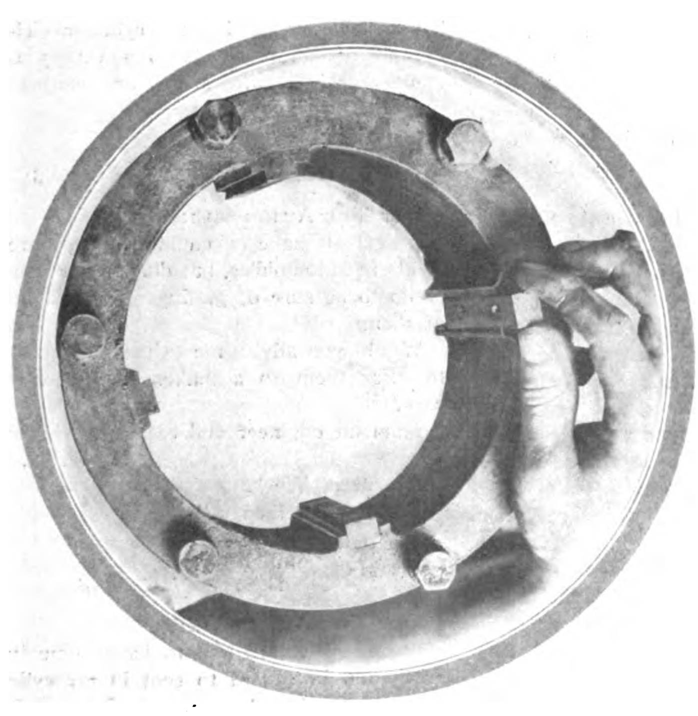

Fig. 3—Showing position of key in clutch. This key is fastened by two pins

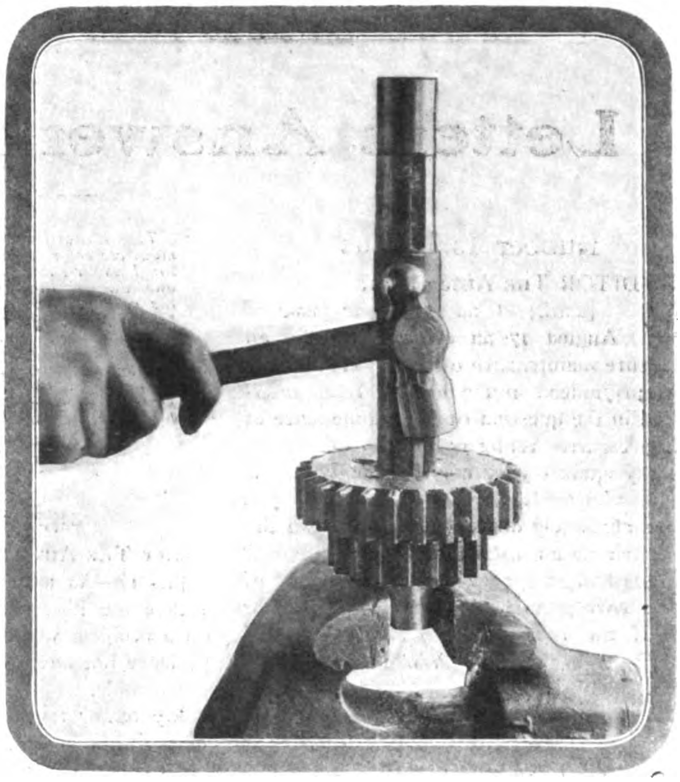

Fig. 4—Method of driving key into keyway when it is desired to hold gears in correct relative position

Whatever the work which is carried on in the garage the owner will find that the arrangements which were made in building it will always, so far as convenience goes, be a factor in the economical upkeep of the car. The finish on the body of the car is always more or less a matter of pride with the owner, no matter in what part of the country he may live. In the case of one who lives within the confines of the city or very close to its borders this upkeep of finish is a very important item. Mud may do a large amount of damage to a car, and here again the danger from this source may be practically eliminated by care and foresight. The only care really required is to take the mud off before it has time to harden. If the mud has once hardened and is then broken off, it will be found that the varnish has evidenced a penchant for adhering more strongly to the mud than to the body of the car. If a mild stream from a hose is turned on the car before the mud has hardened the deleterious effects will be entirely prevented and the life of the finish materially increased. A point to remember is that the temptation to turn the nozzle so that a hard stream will be projected against the delicate surface of the car must be overcome. It is true that the mud and dirt will come off much more quickly under the influence of this sort of stream, but the varnish will do the same, and hence care must be used.

Soft water is better than hard not alone for cleaning a car, but for the circulating system and the radiator. It is for this reason that many wise automobilists are fitting a rain-water trap to their garages, thus storing sufficient water for these purposes. The radiator should be washed weekly by allowing the engine to run for about three minutes with a soda solution in the water circulating system. Clear water is then run through and drained once and the system refilled.

Letters Answered and Discussed

The Editor invites subscribers to communicate their automobile troubles and personal experiences, stating them clearly on one side of the paper. If the nature of the case permits, send a sketch, even if it be rough, in order to assist to a clearer understanding. Each communication will receive attention in the order of its receipt, if the writer's signature and address accompany it as an evidence of good faith. If the writer objects to the publication of his name, he may add a nom de plume.

Rubber Is Porous

EDITOR THE AUTOMOBILE:

[2,818]—I note in your issue of August 17 an editorial on the air pressure maintenance of tires. While I am not prejudiced in the matter, I am interested in the question of the maintenance of air pressure. While you have considerable to say against your correspondent's assertion as to the making of better tires you have absolutely nothing to say about a tire maintaining a constant pressure. Why not? I have had an experience similar to that of your correspondent. Where does the air go if the tubes are properly made, and why? WILLIAM B. ELY.

Pittsfield, N. H.

Wants Combination Tool

Editor THE AUTOMOBILE:

[2,819]—Perhaps you could tell me in an early issue whether at any time since last January a combination tool of six or seven uses has been noticed in THE AUTOMOBILE. C. F. G.

See page 1416, issue of June 22, 1911, and page 241 of the issue of January 19, 1911.

Not Enough Clearance

Editor THE AUTOMOBILE:

[2,820]—In order to increase the clearance of my car I wish to raise the springs a considerable distance above the live rear axle. I am not quite sure as to the manner of proceeding with the work, and I would esteem it a great favor if you would give me directions. I am a subscriber to your paper and follow the discussions with great interest. OLD SUBSCRIBER.

Grand Rapids, Mich.

A block of fiber of the required thickness may be inserted as shown in Fig. 1. The block is placed upon the spring plate and the bolts passed through as shown. Care must be taken in this work that a good fit is made.

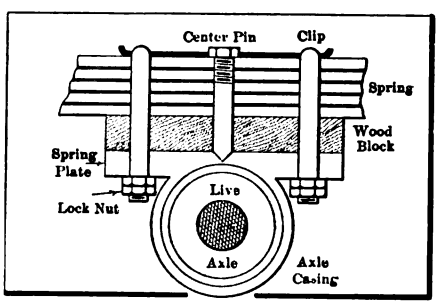

Fig. 1—Showing method of inserting block of wood to increase car's clearance

Engine Vibrates

Editor THE AUTOMOBILE:

[2,821]—As a reader of your magazine I take the liberty of asking your opinion on a problem which confronts me, my experience not having been sufficient to place the trouble.

My motor truck engine is a four-cylinder, 28-horsepower type. The cylinders are cast in pairs; three-bearing crankshaft timing gears in front; flywheel fairly heavy; cone clutch; double ignition; double spark plugs in double caps on left (intake) side; exhaust on right side; extra heavy crankcase. The engine runs very fair at a medium speed, but when running, say, 30 miles per hour the vibration is terrific. Will you please give me your idea of the trouble?

LELAND A. KING.

New York City.

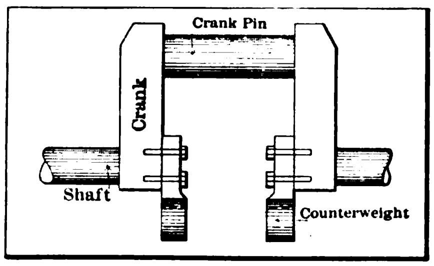

Fig. 2—Method of attaching counterweights in order to balance motor

The engine is probably balanced well enough at low speeds, but when the piston speed increases the forces set up are not properly met. A plan which may be tried is to bolt counterweights on the crank as shown in Fig. 2. The weights should be carefully fitted in order to avoid lost motion, as the result would be a knock, very likely something worse. In fitting the weights take out each connecting rod with piston and rings and weigh them. If there is one which appears lighter than the rest favor that with the weights, which should all be the same shape and fitted on each crank. The gear ratios may not be suitable for the engine speed so that when the car is traveling at 30 miles per hour as you state the engine is really racing.

Jerky Rim Motion

Editor THE AUTOMOBILE:

[2,822]—Being a subscriber to your paper, I take the liberty of asking a few questions.

(1) I find that when I am driving my car below 20 miles per hour the motor runs with a jerky motion. I have cleaned the air valve and have the right adjustment; have filed and set the magneto points, and also inspected the spark plugs, but still the trouble remains.

(2) The transmission, insfead of running with a steady noise, sounds as if it were jerking, although the car does not jerk.

(3) What harm is likely to come from having excessive oil in the crankcase?

J. E. HORTON.

Hartford, Conn.

Questions 1 and 2 depend, probably, one upon the other. Lift the hood of the motor and open the compression cock of one cylinder at a time to determine whether they are all firing properly, or if the trouble is confined to one of them. If it is confined to one cylinder close the gap between the sparking points of the plug a trifle, or test if the insulation is leaky. If the trouble is common to all the cylinders there is probably a shortage of gas at low speeds, or the magneto has become demagnetized.

In the event of too much oil in the crankcase the motor will smoke and carbon will be deposited in the cylinder. The deposit of carbon leads to a variety of troubles, chief among which are overheating and pre-ignition.

Automobile Improvements

Editor THE AUTOMOBILE:

[2,823]—I have a couple of improvements in automobiles, but don't know what to do to be sure of getting any profit out of them.

Would you advise me to patent them or to offer them to a maker of high-class cars?

I am an engineer and expert machinist.

N. W. K.

Aberdeen, Wash.

Patent first, then sell.

Carbon in Cylinders

Editor THE AUTOMOBILE:

[2,824]—I would like to have some information in regard to soot in my cylinders. I purchased a new car five months ago and I now find that the cylinders are

heavily coated with soot. Any advice you can give me will be greatly appreciated.
SUBSCRIBER.

Lancaster, Pa.

Use kerosene or any reliable decarbonizer in removing the deposits. It would be well to let the kerosene remain in the cylinder over night in order to thoroughly soften the carbon before scraping it off. Care must be taken not to scratch the cylinders.

Spark Plug Too Short

Editor THE AUTOMOBILE:

[2,825]—After reading your article on the position of spark plugs in a recent issue of THE AUTOMOBILE I took the cap and plug out of my car to see if it was right. I found that the plug did not go through by 3-16 of an inch. Would you kindly tell me what to do?
C. D. MCGEEHN.

New York City.

The difference in length can best be remedied by buying a longer plug, which will probably be too long. The difference in length on the longer plug may be taken up by means of washers above the spark plug cap.

Insert a Ball Thrust

Editor THE AUTOMOBILE:

[2,826]—The thrust on my clutch continually overheats. It is of the plain type and will not remain cool in spite of ample lubrication. Would you kindly tell me what to do? Any advice which you may give me will be greatly appreciated.
CHARLES PETERS.

Wading River, N. Y.

The installation of a ball thrust would no doubt eliminate the trouble. A type of ball thrust is shown in Fig. 3, and to have it installed it would be necessary to send the car to a well-equipped shop.

Clutch Jerks and Pounds

Editor THE AUTOMOBILE:

[2,827]—I am a subscriber to your magazine and would like to know what is wrong with my transmission or clutch. When running on high there is a jerking and pounding sound in the clutch or transmission. This sound is only when I am running slowly. By partly throwing my clutch out the noise stops to some extent. By giving the engine more power at the same time that I disengage the clutch the noise stops altogether. I have a cone clutch and it does not slip except on hill climbing.
J. R. B.

Paragould, Ark.

If the trouble is in the clutch and not in the ignition, as is very possibly the case, reface the cone with new leather.

The leather will in time rot if it has not been cared for in life. Test the alignment before going to the expense of a new leather.

Wants to Brighten Brass

Editor THE AUTOMOBILE:

[2,828]—Being a constant reader and a subscriber to THE AUTOMOBILE I am taking the liberty to ask a question. Do you know of any preparation or acid which will restore tarnished brass to its natural color? If you would publish the information in an early issue of the paper it would be greatly appreciated.
LOUIS ULLMAN.

New York City.

So far as we know the best method to rejuvenate brass which is covered with verdigris is to use what is commonly known as bath brick and oil plentifully backed up by a supply of elbow grease. If the verdigris coating is not too thick a good brass polish may be used; this will, however, only be of use in cases where the dirt has not penetrated the surface to any great extent. If the parts to be polished are very delicate, they can best be taken care of by a buffing machine.

Puncture-Proof Tire

Editor THE AUTOMOBILE:

[2,829]—I would like to get some information in regard to a device for rendering a tire absolutely puncture-proof. Has there ever been anything invented and put into practice which would render it impossible to puncture the inner tube of a tire? What are some of the appliances that are placed between the inner tube and the outer casing? Have they proved to be a success? I would be very pleased if you would furnish the information.
S. POLITZY.

New Orleans, La.

There have been various devices placed upon the market from time to time which have been very successful in prolonging the life of the tire. As far as we know none have made puncture absolutely impossible.

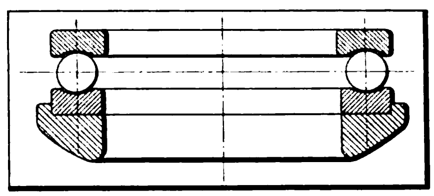

Fig. 3—Showing type of ball thrust to take up thrust on a clutch collar

Piston Ring Sticks

Editor THE AUTOMOBILE:

[2,830]—Could you tell me how it would be possible to prevent the top piston ring from sticking, and how to release it without breaking it? The engine is a two-cycle air-cooled motor and is lubricated by putting the oil into the cylinder with the gasoline. I am using one quart of oil with five gallons of gasoline.

Any information you may give through your letter department will be appreciated.

Topsfield, Mass.
A. E. LAKE.

The reason the top piston ring sticks is probably because there is a thick deposit of carbon in the cylinder. Try using one pint of oil to six or seven gallons of gasoline in order to reduce the carbon deposit. There should be ample lubrication in this quantity of oil, as the proportion generally used is about one pint of oil to five gallons of gasoline.

There is no rough-and-ready method of releasing the ring from the piston. Remove the piston from the cylinder and allow the top ring to rest immersed in a bowl of kerosene over night. In the morning it will be found that the carbon deposit that has found its way behind the rings and perhaps along the sides of the grooves will have become soft and the piston ring can be removed in the ordinary manner. It stands to reason that the top ring will be more inclined to stick than the others as it is subjected to more heat than the others, which causes a quicker precipitation of carbon at this point.

The ring should be a good fit in the groove so that when it expands it will have just sufficient clearance to prevent it binding. If there is too much clearance the carbon easily finds its way behind and causes the trouble you complain about. Never touch the rings with a file. Use a surface plate on which a piece of fine emery cloth has been attached and, holding the ring in the hand flat, a slight rubbing will true the ring and remove all traces of carbon.

Internal Brake Broken

Editor THE AUTOMOBILE:

[2,831]—Would you kindly tell me what to do to repair my brake? The internal brake on one of the wheels does not work and rattles continually, while the other is in good condition. The trouble happened suddenly when a sound as if something had snapped in the drum took place. Since then I have been unable to manipulate the brake.
E. F. G.

New Orleans, La.

The accompanying cut, Fig. 4, shows an assembly of an internal brake. The trouble with yours may be determined by an examination. It is very possible that the spring has slipped from the shoe.

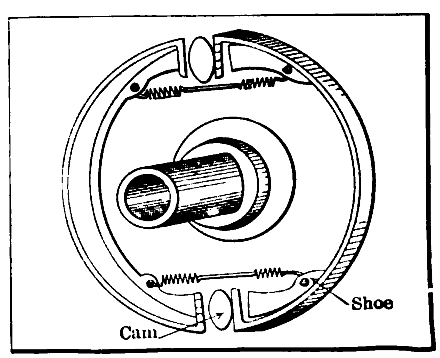

Fig. 4—Showing how the springs are generally held in an internal brake

My 1912 Automobile

Some Conceptions of What the Ideal Car Should Be

Six-Cylinder Car for $1,500

EDITOR THE AUTOMOBILE:

The following is a description of a car which I think would meet my ideal for a 1912 design:

The motor should be of 40-horsepower, silent-Knight type, six cylinders, cast in pairs, and a gear-driven eccentric shaft. The bore would be about 4 1-4 inches and the stroke 5 1-4 inches. The engine should have large bearings and plenty of hand holes for inspection purposes. Crankshaft should be of electro-manganese nickel steel.

The ignition should be double, with high-tension magneto and batteries, adjustable spark. Lubrication, positive force-feed and splash. Carburetion, heated with automatic double jet. The drive should consist of a cone clutch, four-speed selective sliding gear set with a worm-gear drive shaft. Cooling water should be circulated by means of a gear-driven centrifugal pump, the radiator being square tube, efficient and durable.

The front springs should be semi-elliptic, long and wide, with oil cups. The rear springs should be three-quarter elliptic, fitted with oil cups, and of good length and width. The wheel base should be from 116 to 120 inches in length. Tires, 34 x 4 or 36 x 4 1-3 inches. The rear axles floating, the front axles of I-beam section. The brakes should be on the hub and transmission, the first set connected with the clutch. The universal joints should be on drive and cone shafts. The differential and drive should be adjustable and accessible, with ball bearing change speed gears amidship, of best material. Tie rod should be in front of front axle. Car should have brake eveners, torsion rods, twelve spokes in wheels all around, distance roads and the frame should be strong and well braced and contracted back of front wheels.

The equipment should be complete, with control parts on top of steering wheel, tire pump, self-starter, gas tank, oil side and tail lamps, acetylene headlights, horn, complete tool and repair equipment, good cleanable muffler with cut-out, automatic speedometer, shock absorbers, roller and ball bearings and everything that will tend towards a state of being dustproof and silent. All parts should be interchangeable.

The weight of the car should not be above 2,400 pounds when equipped, and the speed ought to be up to sixty miles per hour. The gear and brake handles must be in easy reach, and the steering so arranged that it is possible to take up lost motion. A price list of parts should accompany the car, and prompt repair service should be made a feature. The automobile should be made by a concern who intends to stay in the business. A neat appearance should be made an object, the car being clean-cut and not loaded down with junk and dust catchers. I believe in a four-passenger torpedo body, with a place to carry all necessaries, as well as a spare tire. Price, $1,500 to $2,000.

N. T. G., Md.

Turbotsville, Pa.

A Rational Buyer

Editor THE AUTOMOBILE:

After several years of experience with cars of different makes ranging from 3 1-2 horsepower to nominally 100 horsepower, the ideal car of my choice would be one of approximately 25 horsepower. I consider that it is possible with a car of this size to do anything that a car of 50 horsepower or more can accomplish, and, what is more, the reduction in weight would materially assist in the keeping down of tire expense. The motor should be a bloc motor either of the best design of poppet valve or with some accepted valveless design. Perhaps I might have a slight inclination to the latter, as it is something new, and taking care of my car as I would of a thoroughbred horse, it would have all the attention lavished upon it that I understand this type of motor requires.

The bore should not be more than 4 inches with a stroke of from 4 1-2 to 5 inches. The ignition system I prefer is a plain straight high-tension magneto in which the armature and pole pieces are capable of being rotated at the same time so as to give maximum power at all engine speeds. I would like the crankshaft to have five main bearings and instead of drilling it hollow for the entire lubrication I would feed a pipe to each cap of the bearings at its bottom side so that oil could be forced into the bearings under a pressure of, say, 5 pounds per square inch. The oil pump should be of the positive plunger type driven by an eccentric strap off the half-time shaft, but so situated that it would be readily removable. I would do away entirely with under-trays and have the sides of the crankcase cast with integral webs that would answer the same purpose. The clutch would be of the conventional cone type with the male boss made from pressed steel slotted at various points so that the leather would not be compelled to fit tight against the entire face of the flywheel. The spring operating the clutch should be of the enclosed type with simple adjustment and ball thrust so that there would not be any thrust on the crankshaft while the motor was running with the clutch in.

Three speeds and reverse are sufficient for this size of car if properly designed, but I should prefer another gear for the fourth with an over-direct drive so that the direct drive would be about 3 1-2 or 4 to 1 on third speed. The final drive would be by full-floating live rear axle, the propeller shaft enclosed in a tubular casing terminating at the forward end in a forked joint. I should prefer worm drive.

As regards suspension it would depend upon the weight of the chassis, which in my opinion should not exceed 1,800 pounds. The dimensions of the chassis would have some bearing on the length of wheelbase. The chassis should be 80 inches behind the dash to the rear end of the frame and the radiator should be set 2 or 3 inches behind the front axle. With a monobloc motor the hood would not take up a lot of room so that the wheelbase would not exceed 110 inches. The car should be fitted with worm and block steering and be capable of turning in a 32-foot street. The gasoline tank would be placed in the cowl of the dash so as to leave the compartment under the driver's seat free for tools, and access thereto would be had by three doors, one at the driver's heels and one on either side of the body. The running boards would be entirely free from all encumbrances and the tires would be set in a sunken well behind the rear seats. The body would be a two-seated coupé with a leather top so that the passengers would be sitting amidships. I cannot see any advantage in left-hand control, so would have the control on the right side. Some people like to have the dash free from all fittings, but I would like to use it for as many as I could conveniently get there—not useless ornaments, but fittings that would tell how the oil and water were circulating, cylinder testing cutouts, etc., in short what the market afforded that would help in cutting down costs in upkeep. This may sound foolish, but it is better to spend a few dollars on a fitting that will positively save in gasoline consumption than to put money in the pockets of the oil company.

Some people want a car that will run without trouble, and so do I; but instead of kicking at the bills I am prepared to try to reduce them. One cannot expect a manufacturer to tune a car up to the pitch that it will require no further work on the part of the owner. The running in of 500 to 1,000 miles makes all the difference, and to take advantage of the bettered condition it is necessary to do something oneself.

The price of the car with the necessary material for longevity would be about $1,700 without extras, and if such a car were turned out and the advantages were placed before a discriminating public there is no reason why it should not meet with the same success as the cheap imitation of the same power. M. P. H.

New York City.

Sleeve-Valve Motor

Editor THE AUTOMOBILE:

I am sending herewith a description of a car which, if it could be made for the specified sum, ought to set the world on fire. I do not know the cost of manufacturing Knight motors or the royalty required upon them, but I am sure that this car would prove a world-beater.

The engine should be of the Silent-Knight type having upward of 28 horsepower, a bore of 4 1-4 inches and a stroke of 5 1-4 inches. It should be equipped with dual ignition and lubricated by the mechanical force-feed system. The number of the cylinders should be four and they should be cast in pairs.

The car should be shaft-driven, with a cone clutch with cork inserts and a selective type gearset located in the center of the chassis.

The suspension should be on semi-elliptic springs forward and three-quarter-elliptic springs rear.

The wheels should be arranged so as to give an 118-inch wheelbase with 36 x 4 1-2-inch tires of the best quick-detachable demountable type.

The axles should be equipped with roller bearings, both front and rear.

The control should consist of clutch and brake pedals, emergency pedal and accelerator pedal.

The equipment of this car ought to be perfect and entirely complete, the electric lighting being by means of the Gray & Davis dynamo or the entire electric system by means of the Delco Company's product, including self-starter and all the other refinements accompanying the system. A good speedometer-clock combination must accompany the car and the switch equipped with a Yale lock. The rear springs should be fitted with shock absorbers to ease the motion of the car, and for the comfort of the passengers a foot rail should be placed in the tonneau as well as a robe rail. A wind shield and top should be provided. Adequate license holders must, of course, be in place.

The mechanical fittings throughout should be of the best, all oiling places convenient and grease cups large. The gasoline tank should be equipped with a gauge as well as a lock. The tool box, located on the running board, should be provided with a full set of tools, including jack, etc.

This car ought to weigh when completed about 3,200 pounds, the body being of the five-passenger touring style, and should sell for $2,000 to $2,500. K. P. HEINTZ.

Cumberland, Md.

Comfort the Main Idea

Editor THE AUTOMOBILE:

I have read with much interest your letters on the 1912 car, and it seems to me that many of your readers are wasting space on items of car construction that are not of real importance to the car owner. Two inches longer or shorter in the matter of wheelbase do not make any difference in the running of a car; one magneto is often as good as another and troubles with that adjunct are not very numerous. The big question that does concern every car owner is the matter of arrangements for carrying the tools and extra baggage. This is a department in which every 1912 automobile can be improved.

In carrying tools it is common to carry the tire repair outfit under the rear seat. This is very awkward. Supposing a valve leaks and the tire does flat, it is necessary to get the jack and tire pump from under the back seat. There may be three women in the tonneau and it may be raining. The entire comfort of all three has to be upset. They have to get out of the car, because the rear seat cushion is so big and awkward that one cannot possibly get at the jack and pump until the cushion is removed. It is not very pleasant to ask women to get out of a car onto a muddy road on a cold, wet day. But once the women are out the task has but just begun. The jack and tire pump are generally the heaviest tools in the compartment and are usually placed at the bottom of it. In order to get them one must first take out some inner tubes, perhaps a side curtain or two (if they are not already in use) and there may be some other tools to remove before the jack can be got at. The net result is that everything, including the equanimity of the party, is upset simply in order to get a jack and a tire pump.

There is a remedy: Tire tools, including jack and pump, should be carried in the same place, and it should be in a convenient position. If there is no room on the running board a compartment should be provided under the chassis midway of the car on the left side. This may be just in the rear of the gearbox. Access can be had through the left tonneau door by means of a hinged door in the floor immediately inside of the tonneau door. Raising this door will not interfere with the tonneau passengers, and it is as convenient a place as can be found. F. J.

Elgin, Ill.

THE AVERAGE CAR

The invitation to our subscribers to describe their ideal 1912 car has struck a popular chord. The responses show a wide appreciation of the salient points of car design and a knowledge of the points which tend to reliability and comfort. THE AUTOMOBILE *hereby continues the invitation to its readers to mail in their conception of the features which should be embodied in next year's car. The information given should include such points as:*

Horsepower	*Stroke*	*Drive*	*Front axle*
Cylinder type	*Ignition*	*Springs*	*Control parts*
No. of cylinders	*Lubrication*	*Wheelbase*	*Body features*
Cylinders, how cast	*Clutch*	*Tire sizes*	*Equipment*
Bore	*Gearset*	*Rear Axle*	*Price*

In addition to giving these details the reasons for your points of selection should be stated concisely and clearly.

As a benefit in the matter of comparison some details of the average cars for 1911 are given below.

Each communication must be legibly written on one side of the paper only; it must be properly signed with the writer's full name and address, and if the writer does not wish his own name to appear in print he may request the use of any nom de plume.

Any reader desiring to make line drawings, showing details of his ideas of his car or some of its parts, is requested to do so.

Editor THE AUTOMOBILE.

DETAILS OF AVERAGE 1911 CARS WHICH WILL ENABLE READERS TO MAKE COMPARISONS IN DISCUSSING 1912 MODELS

	$1,000 *and thereabouts*	$1,500 *and thereabouts*	$2,500 *and thereabouts*	$4,000 *and thereabouts*
Horsepower	20.5	29.525	35	43.66

Little Bits of Motor Wisdom

Pertinent Pointers for Repairman and Driver

A series of short stories that will tend to keep the automobilist in touch with matters mechanical and otherwise—quick soldering jobs, the use of the dowel pin, necessity for methodical inspection, aid to selection of proper-size tires, how to calculate clearance in per cent., amount of vapor in air, etc.

SMALL SOLDERING JOBS—It very often occurs that the automobilist will reach the determination to do a small soldering job rather than send it out and suffer the delay which such a proceeding generally entails. With very few exceptions more disappointments have resulted from attempted soldering, all because a few trifling but necessary preliminaries were not observed.

The first and perhaps the most important precaution to be observed is that the parts to be soldered are absolutely clean. Not apparently clean, as that will never suffice, but thoroughly, mechanically and chemically clean. Every slightest particle of grease, dirt or rust, as well as any other foreign matter, should not only be carefully removed but kept away by means of an application of what is known as flux.

After the primary or mechanical cleaning has been accomplished by means of a scraper, file or alkali solution, or perhaps by all three, apply the flux immediately so that the oxide film cannot regain a hold on the metal. If a liquid flux is used the metal to be soldered should be first heated and then the liquid applied. If the flux employed is borax or resin in solution it may be applied to the metal before it is heated.

The parts to be soldered are then heated until they are of sufficient temperature to keep the solder at melting point for the length of time required to finish the work if the parts are fairly small; or in any case until a fair quantity of work is done. The correct temperature varies with the different materials treated and may only be well learned by actual experience or by watching the work of others. Very good results will, as a rule, be obtained even by the novice if it is remembered that the metal should not be too hot. If the work is carried on at too high a temperature the oxides of the metal will form on the surface in spite of the flux and the result will be disastrous as far as a good soldering job is concerned. Sufficient temperature for the average work may be obtained with the ordinary blowpipe and candle flame shown in Fig. 1. In soldering large pieces the metal surrounding the part to be soldered will carry the heat away from the joint too rapidly owing to the high conductivity of metal; hence in a case of this nature it is necessary to use a kerosene or gasoline torch.

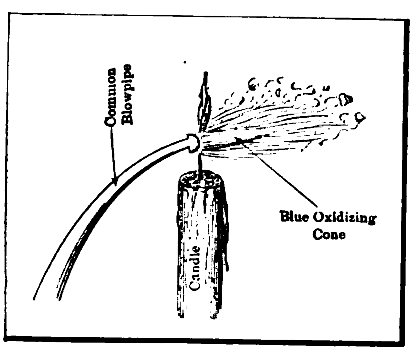

Fig. 1—Method of using ordinary blowpipe with candle flame for small soldering jobs

The solder itself performs the office of a metallic cement and is generally composed of tin, lead or a combination of both. It is placed upon the joint and smoothed down by means of the soldering iron or bit, which is of different materials, generally having a copper head. In soldering aluminum a pure nickel soldering iron should be used to avoid discoloration of the metal. Before starting to solder the bit is tinned with the solder to be used, or with pure tin. This tinning process lends much to the certainty of a good result and is carried on as follows: The bit is first scraped with a piece of emery or a file until all particles of the scale with which it will generally be found to be covered have been removed. It is then plunged into zinc chloride and heated to the working temperature, which must be below redness. A stick of tin is held against the bit and will be found to adhere to it if it is not too hot.

When determining whether a certain piece of work should be soldered or welded it must be remembered that the solder is not very strong so far as tensile strength is concerned and that while furnishing a very cheap and good connection a soldered joint is not to be depended upon where any great strains are to be endured.

CYLINDERS REQUIRE REBORING—The metal in the cylinder walls is too soft to stand continuous service. Designers desiring, in the first place, to have the weight efficiency as high as possible take advantage of the fact that white metal is dense, hard and strong. Gray iron, on the other hand, is soft and is likely to be of varying texture. White metal in a cylinder is induced by so regulating the charge that it will take on the property technically known as "chill." This "chill" is not to a great depth in good cylinder metal, so that in order to preserve the white metal surface the finish must be restricted. It will be remembered that all finished metal is machined off, and what is wanted in completed cylinders is just enough finish to permit of making a smooth bore without cutting through the white metal coating into the gray iron texture.

USE OF DOWEL PIN—Where two surface plates are to be placed one upon the other

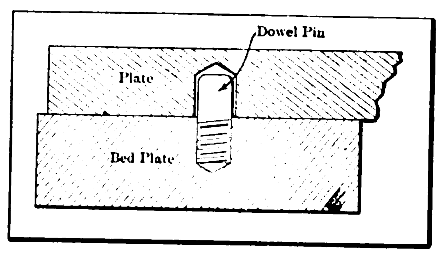

Fig. 2—Illustrating a dowel pin used to secure proper relative positions of two flat plates

and have always the same relative positions a pin known as a dowel is employed. The usual form of this pin is shown in Fig. 2, which shows a section through the two surface plates and the manner of fitting the pin. The bed plate is tapped and the pin screwed in for about one-half its length. The other plate is then drilled in the proper position so that there is no possibility of misplacing the plate.

In drilling the plate which fits over the pin care must be taken that the hole is not too large, as otherwise it would be possible for the plate to slip in any direction, and this would defeat the purpose of the pin. One pin does not entirely fix the relative positions of the two plates. It takes two to obviate any possibility of rotation. One pin would fix the position if there were guide plates on either side of the plates to prevent rotation.

DOGS MUCH USED—One of the useful appliances in the way of securing cover plates, manifolds, etc., in their proper positions is the dog. The form that this takes in automobile practice is shown in Fig. 3.

There are two faces which bear against the manifold flange or against the part to be held in place. The bolt passes through the center of the arm and into a tapped hole in the part to which the manifold is to be connected. There are endless variations to the shape of the dog, even at times taking the form of a flat plate, but the purpose fulfilled is the same, namely, that of holding various pieces of metal in place, which it would be unsuitable to hold by means of separate bolts. Since one bolt is performing the duty of several, it should be of sufficient strength to sustain the strains to which it will be subjected in this case; therefore the diameter should be relatively large.

From an inspection of the illustration it is evident that the dog will be subjected to a large bending stress, and hence will have to be of strength in this direction where any strain is to be placed upon the bolt. A permanent set in the dog would result in a leaky joint since the faces would not bear equally against the flange.

Methodical Inspection Necessary—Even the latest convert to the world of motoring recognizes the necessity of an occasional tour of inspection about the various parts of the car. Inspection in itself, while a *sine qua non*, is not sufficient to fully determine the fitness of the car on all occasions. The motorist should observe a certain routine which will suggest itself by experience or preference, rather than make a random inspection which, while it may accomplish the desired end ninety-nine times out of a hundred, will be sure to result in the overlooking of some important detail sooner or later.

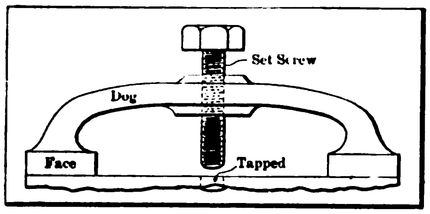

Fig. 3—Type of dog often used in motor construction to hold manifolds in place

A good method to pursue, for the man who owns his own garage and enjoys the work which must be done about the car, is to post a schedule on the wall of the garage. Oiling charts are generally furnished by the makers of the car with directions as to how often each part is to be lubricated and what sort of grease or oil to use. Follow this advice closely and remember that a new car requires more oil than an old one. A wiring diagram is also a valuable adjunct, and will aid the motorist to a large extent in his occasional survey of the car ignition system.

A list of parts which are apt to become clogged may be also made up and will consist of the gasoline piping, water jacketing, radiator, carbureter needle valve, etc. The weekly washing-out of the radiator with soda solution will obviate the dangers of scale. Leaks, knocks and squeaks must be sought for and remedied as soon as they appear, always remembering that where a repair is of a temporary nature it should not be allowed to remain long without being replaced by a permanent one. After some experience has been gained the habit of methodical inspection will be deeply ingrained and the rapidity of the work will be markedly increased.

To Select the Right Size of Tire—The first point to take into consideration is the weight of the car, and this is a matter that seldom occurs to the owner. By weight is meant the complete weight of the car loaded with full equipment of passengers, tools, luggage and full tanks. Even before the question of sizes of tires is considered this should be found out and a certain margin for safety allowed in case additional weight is carried from time to time.

The way to ascertain the weight is to place the front wheels on the scale first and the rear wheels afterward to find what weight is carried on each axle. This amount halved will give the proportion of the total weight each wheel has to carry.

The following table shows the weight a given size tire is made to carry and the pressure to which it should be inflated:

Diameter of tire in inches	Maximum allowable weight on wheels	Air pressure in pounds per square inch
2 1-2	225 pounds	50
3	350 "	60
3 1-2	600 "	70
4	750 "	80
4 1-2	1,000 "	90
5	1,000 "	90 to 100
5 1-2	1,200 "	100 to 105

If the flexure of one tire is greater than another for the same pressure it is as well to reduce the pressure of the highest to correspond with the other to equalize the flexures. There is danger of extra tire depreciation if one tire is blown up stiffer than another.

Cushioning the Body.—In order to take up the shocks which will be transmitted through the office of the chassis to the body of the car, a rubber insert is often placed in such a way that there is no direct contact between the two. A manner of installing the rubber cushion is illustrated in Fig. 4. The angle iron bracket which takes all the weight is equipped with a box-like cover which contains the rubber insert. The box is continued to a sufficient height to hold the body in position besides holding the rubber. This box is shown to be cut away in the illustration in order to indicate the relative positions of the parts.

Weight of Vapor Air Will Hold at 32 Degrees Fahrenheit—Primarily the weight of any vapor that air will hold will depend upon the temperature to which it is raised, and the higher the temperature the greater will be the volume, and the lower the weight of the air. A state of saturation will follow for each temperature, and while the volume of air will increase with increasing temperature, thus decreasing weight, so that the capacity of the air for vapor will increase. The weight of vapor per hundred pounds of air, at different temperatures, may be determined in the manner as follows:

$$W = \frac{62.3 \times E}{29.92 - E} \times \frac{29.92}{p}$$

When,

E = elastic force of the vapor at the given temperature, in inches of mercury.

p = absolute pressure in inches of mercury, = 29.92 for the pressure of the atmosphere as ordinarily taken.

w = weight, in pounds, of vapor, for complete saturation, at the given temperature, at which elastic force is determined.

The vapor-carrying ability of the air is of the utmost importance in connection with carburetion, since, if the air is not in a state to hold vapor of gasoline to the desired extent, the results will fall off accordingly. The accompanying table will serve to render comparison potent, as well as to clearly indicate the reasons why atmospheric conditions influence the performance of cars in practice.

Capacity of Atmospheric Air for Vapor at Different Temperatures.

Temperature in degrees Fahrenheit	Pounds per cu. ft. dry air	Pounds of vapor in one pound of air	Weight in pounds cu. ft. saturated air	Weight in pounds cu. ft. vapor in air	A|V
32	0.0807	0.00379	0.0802	0.000304	263.7
42	0.0791	0.00561	0.0784	0.000440	178.18
52	0.0776	0.00819	0.0766	0.000627	122.
62	0.0761	0.01179	0.0747	0.000881	85.
72	0.0747	0.01680	0.0727	0.001221	59.5
82	0.0733	0.02361	0.0706	0.001667	42.3
92	0.0720	0.03289	0.0684	0.002250	30.3
102	0.0707	0.04547	0.0659	0.002997	22.

The ratio A to V clearly indicates the rate at which the air changes in its ability to sustain a vapor, and also the effect produced on the weight of vapor per cubic foot of the air. A close inspection of the table given above will also explain the great advantages of using preheated air for vaporizing the gasoline that is to be burned in the motor, as this air is able of absorbing a comparatively high amount of fuel.

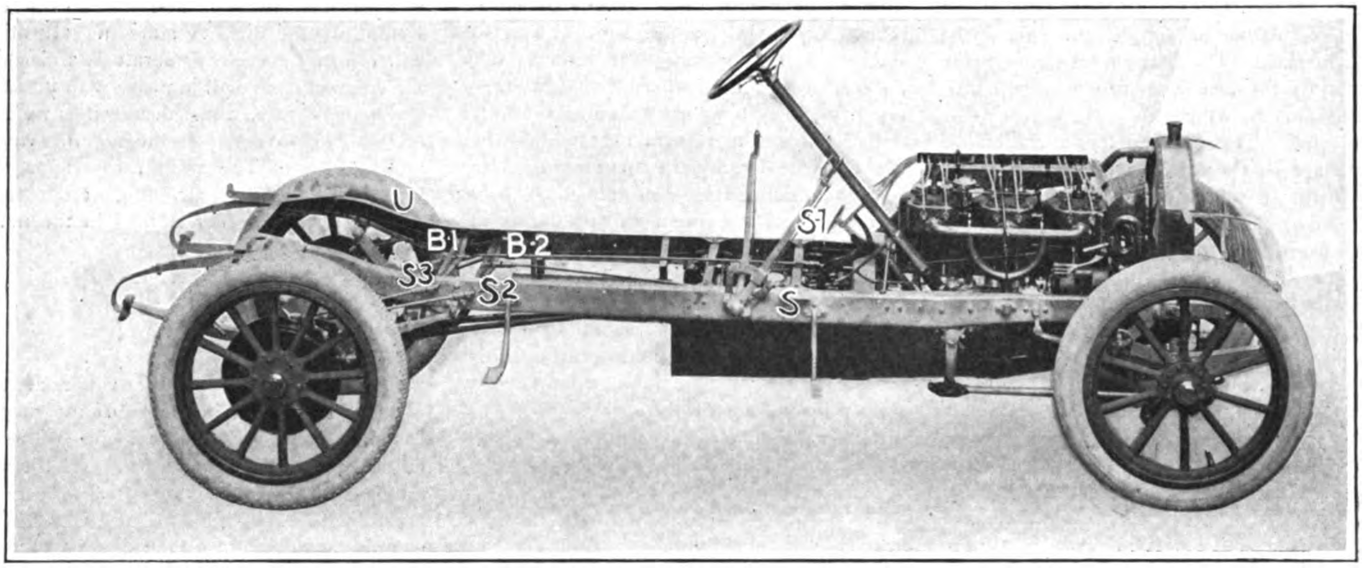

Fig. 1—General appearance of the Pierce-Arrow six-cylinder chassis

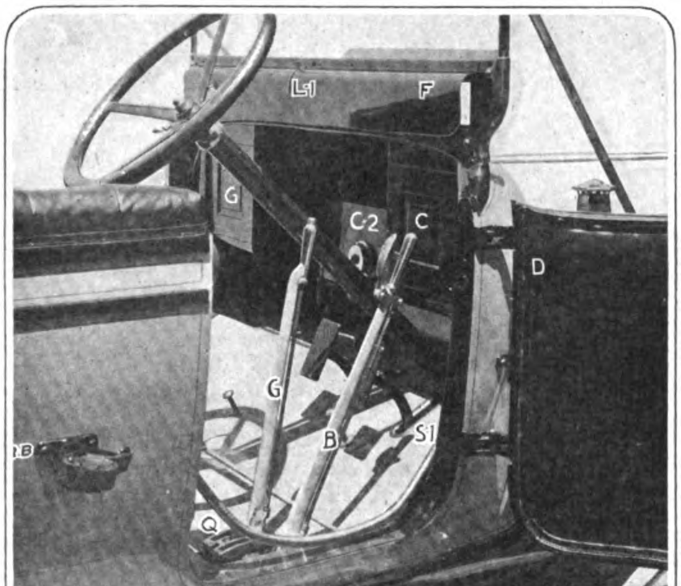
Pierce-Arrow 1912 Models

Few Material Changes in the Smaller Cars



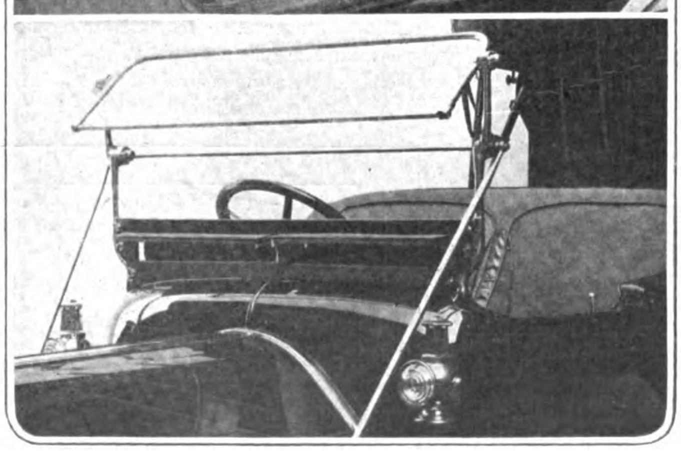


Fig. 2—All doors are made to open, showing how the levers are placed entirely within the body. The new ventilator can also be seen

Fig. 3—Showing the new type of windshield, the open flaps of the ventilator and the neat side lamps

TO place concisely before purchasers of cars the offerings of the Pierce-Arrow Motor Car Company of Buffalo for the ensuing season it is here proposed to deal with the various models separately in order to avoid confusion. But as a general introduction it may be mentioned that the new models are not characterized by any radical changes. The principal change of note is found in the largest model manufactured by this concern

For the sake of clearness it is necessary to refer to the dimensions of last season's models to enable the reader to draw a comparison with the new model. Much discussion has taken place in technical circles relative to the rating of gasoline motors in the endeavor to come to some tangible solution of the present puzzling situation. The tendency of the last year or two among designers seems to point to a penchant for the long-stroke motor, and an instance of this is found in the new "66" Pierce-Arrow. The past season's model had a bore of 5 1-4 inches with a piston travel of 5 1-2 inches. According to the accepted rating adopted some years ago this would give a horsepower rating of 66, but in the new motor the bore has been decreased by 1-4 inch to 5 inches and the stroke increased by 1 1-2 inches to 7 inches, and according to the formula the motor would appear to be less powerful. This is due to the fact that the piston travel is taken at 1,000 feet per minute irrespective of stroke. A more rational manner of viewing the situation is by considering the comparative piston displacement, which is in reality the main factor. The piston displacement of the new model is 770.67 cu. ins., while the displacement of the model of last year was 714.36, which shows an increase of 56.3 cu. ins. for the 1912 motor.

The piston travel per minute being presupposed, according to the formula, to be 1,000 feet per minute, it is interesting to see how this compares with the motors under consideration. The 1911 motor required 1,143 revolutions per minute to attain the above-mentioned piston travel, but in contrast to this the new long-stroke motor with its 7-inch stroke requires but 857 revolutions per minute to accomplish the same piston travel. Block tests of the new motor have been carefully carried out and show that the new motor has an advantage of 15 horsepower over last year's model at 1,000 revolutions per minute.

The general appearance of the different models of Pierce-Arrow cars as far as it relates to the chassis details can be seen by referring to Fig. 1, which shows the right side of the chassis.

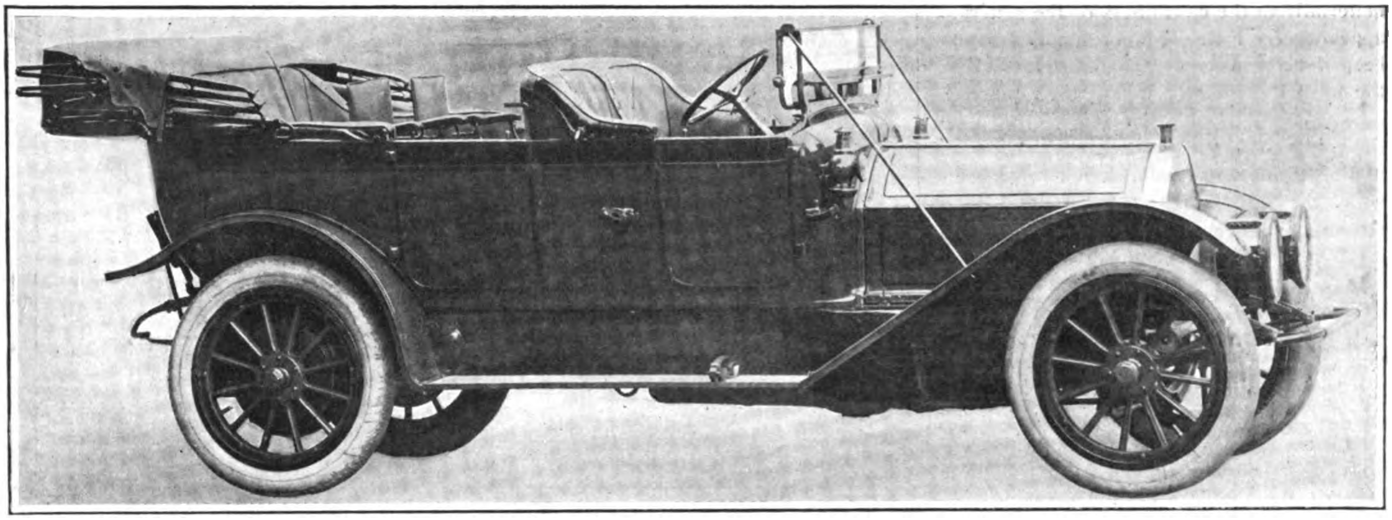

Fig. 4—48-horsepower seven-passenger touring car with fore-door flush-sided body

The rear end of the chassis is given a slight up-sweep to take care of the three-quarter elliptic suspension, and the method of controlling the brakes is also shown.

The rods from the pedal or side lever pull upon the cross bars B1 and B2, which are attached to the side rods that operate the brakes by means of universal-jointed swivels, S2 and S3. As the brakes may not both have the same adjustment the slots in the chassis are cut sufficiently long to allow the cross bars to pull more on one side than the other if necessary to permit of equal braking effect on both of the rear wheels. With the present tendency for flush-sided bodies, which necessitates a wider framework for the upper structure, the side runners of the body rest upon the brackets S and S1 shown in Fig. 1. The method of shackling the front springs can be seen as well as the method of supporting the cross-arm of the steering after leaving the box beneath the chassis frame.

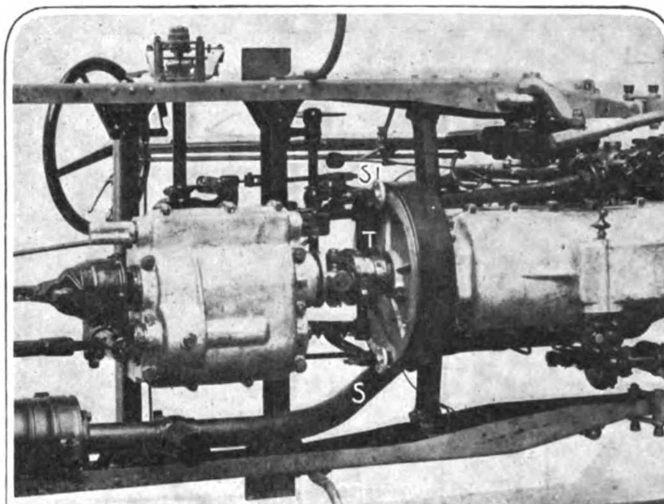
Figs. 2 and 3 show two interesting innovations to this line. All doors are made to open in the manner shown in Fig. 2, and the new method of placing the levers B and G entirely inside the body is also depicted. The body is wider both front and rear, thereby giving greater comfort to the occupants of the tonneau.

The dash is formed in the shape of a cowl, the inside of which is fitted with closets provided with locks to facilitate the storage of such parts as may be most often wanted, such as goggles, maps and the like. The spark coil for the supplementary ignition is placed between these two boxes in the manner shown and a new switch is provided thereon with a connection that gives both battery and magneto ignition at the same time. Alongside the coil is a lighting attachment which permits the gas headlights being turned on from the seat, the spark being furnished automatically.

A new glass front with a rain vision fold has been adopted and the new front and fenders are dished to give greater rigidity and are made of steel, the bolts and rivets not being in evidence. In order to maintain perfect ventilation without causing a draft to the forward compartment of the car a ventilator unique in design has been incorporated in all the open models. Fig. 2 shows the rear view of the windshield and it will be noticed that the lower part is fitted with a metal flap F in the center of which is a lever L1. This lever controls two windows which are plainly shown in Fig. 3. The air that passes through these windows, when open, is caused to descend to the lower part of the front compartment, owing to the shape of the flap inside the body, which has the effect of expelling the heated air that rises through the floorboards. Another new point in next year's models may be seen by referring to Fig. 3, which shows the new side lamps that have been adopted.

The general lines of the three models of Pierce-Arrow cars are almost identical as far as appearance goes, the variations in dimensions constituting the main differences.

The 48-horsepower, seven-passenger touring car can be seen by referring to Fig. 4, which shows very clean design. Inside guards are fitted to the mudguards both front and rear, and the valances fitted between the chassis and the running boards add



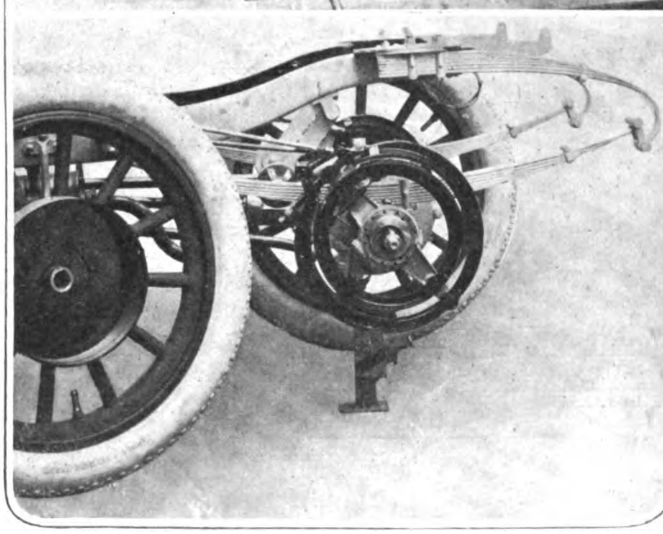


Fig. 5—View of the Pierce-Arrow chassis from below, showing the new clutch stops and the brackets on which the body rests

Fig. 6—Suspension of the rear of the chassis which has been slightly modified, showing the braking mechanism

materially to the cleanliness of the general appearance. Exterior door handles have been done away with, small levers set in the top of each door taking their place.

The 36-Horsepower Model

The engine will be the same size as last year, the bore being 4 inches and the stroke 5 1-8 inches. Referring to the illustration of the motor shown in Fig. 9 the general arrangements of the left side of the motor will be seen. The motor is supported by the cross members C and C1, which are attached to the crank chamber by long through bolts, the upper lips of the supports resting upon the side members. The cylinders are cast in pairs with T-shaped heads and the internal details of the motor are shown in Figs. 8 and 12.

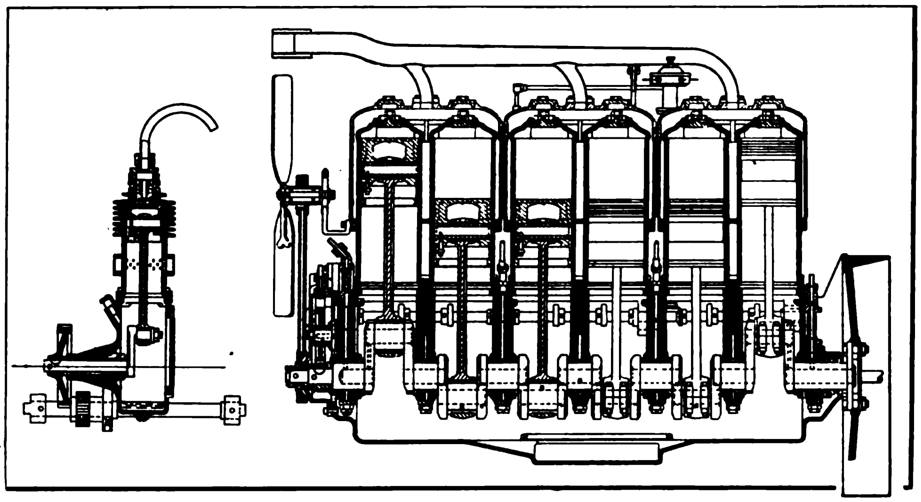

Fig. 8—Lateral cross-section of a Pierce-Arrow motor with seven-bearing crankshaft and the section of the air pump for tire inflation

The train of half-time gears is placed in front of the motor and enclosed in an aluminum housing. The shaft that drives the pump carries at its forward extremity immediately after leaving the casing a gear which is used to drive the air pump P shown in Fig. 9. The gears G1 and G2 are caused to mesh by the use of a small lever not shown in the illustration. A sectional view of the air pump is shown in Fig. 8. The water flows to the intake pipe of the centrifugal pump P1 and is forced to the bases of the cylinders at the points W1, W2, W3, a universal joint U of the Oldham type being interposed in the driving shaft to take care of alignment and permit of easy assemblage. The rear end of the pump shaft is extended through the casing of the pump and is fitted with a tongue joint C2 so that an electric generator may be driven direct where such and outfit is desired. The crankcase has four bosses, B1, B2, B3 and B4, already provided with bolts so that the generator can be bolted on. The cylinders on this and both of the other models will be tapped for S. A. E. standard spark plugs, 7-8 inch in diameter and 18 threads.

The internal and external brakes, the design of which can be seen by referring to Figs. 6 and 7, are much larger, the brake drums being 14 inches in diameter and 3 inches wide. The rear springs have less arch, the upper portion of the half springs being clipped on the under side of the gusset plate instead of on the top. The springs, being almost flat, constrain the rear axle to move in an almost vertical path, thereby eliminating the action of the brakes going on when the car bounces or when there is a difference of position owing to the car being loaded or unloaded.

Fig. 5 discloses a new feature on Pierce-Arrow cars for the coming season. In order to facilitate the changing of the gears two friction pads are fitted at S and S1 which form clutch stops checking the rotation of the male member of the cone clutch when this is withheld. A ball thrust collar T is used on all the new models and the transmission cover has had to be altered to accommodate the gear shift, which has been placed 2 inches inboard. The details of the gear shift are shown in Fig. 11, in which an interlocking device is seen preventing the engagement of the clutch with the gears half in or with two sets of gears in mesh at the same time. The shafts have been considerably

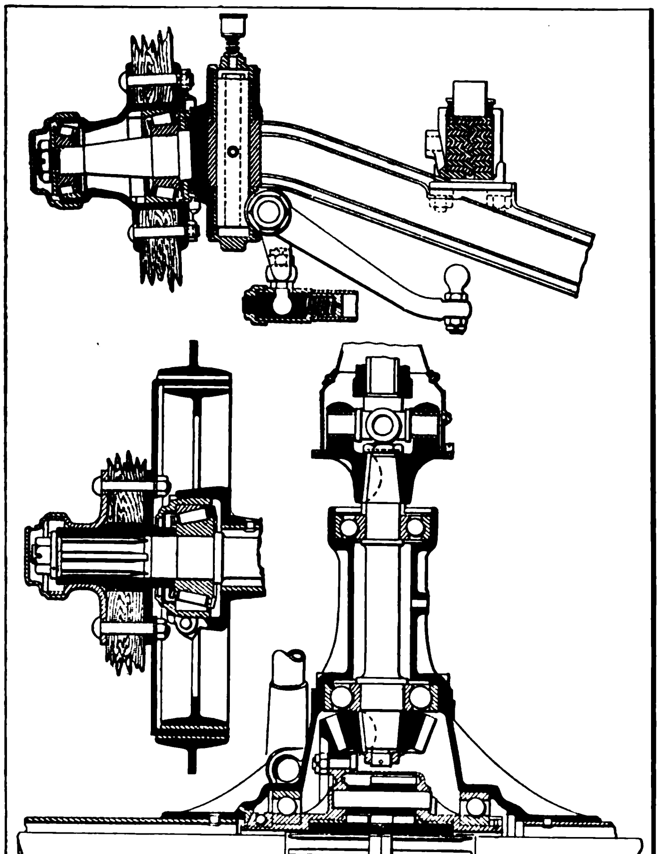

Fig. 7—Front and rear axle of the Pierce-Arrow, showing the details of the general assembly of the differential and front knuckles

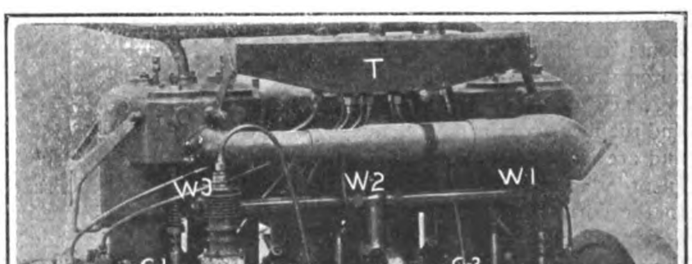

Fig. 9—View of the left side of the Pierce-Arrow motor, showing the air-pump, water and oil pumps, lubricating oil tank and leads

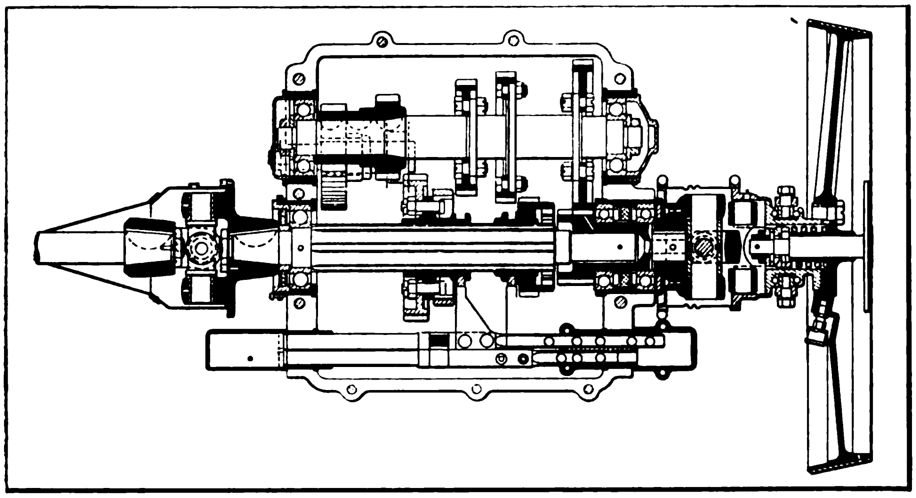

Fig. 10—Sectional view of the clutch and transmission assembly showing the method of assembling the parts

strengthened and the primary shafts on which the gears slide are milled with six feathers or splines instead of four as heretofore. The rear springs are 4 inches longer and have less arch. A gasoline gauge is fitted on the dash which shows at a glance the amount of gasoline in the 28-gallon tank.

The 48-Horsepower Model

The size of the 48-horsepower motor remains the same as last year, viz., 4 1-2-inch bore with a stroke of 5 1-2 inches. The general details are similar to the motor of the "36" in all essential features. Clutch stops are fitted in the manner shown in Fig. 5 and the same remarks that were made in respect to the transmission of the smaller car apply to this model also.

The internal and external brakes are 2 inches larger in diameter, and the faces are 1-4 inch wider. The rear springs are 4 inches longer and have less arch, and the half springs are attached to gusset plates in a manner similar to that which obtains in the 36-horsepower chassis. In other respects the chassis is identical with last year's models, but the bodies are entirely of new design. The general appearance of the seven-passenger touring car fitted to the 48-horsepower chassis is shown in Fig. 4. The rear seat of this body is 54 inches wide and 21 inches deep; the height from the floor to the top of the cushion is 16 1-2 inches. The distance between the back of the front seat and the back of the rear seat is 40 1-2 inches, while the width of the front door is 20 1-2 inches and that of the rear door 22 inches. New folding extra seats in the tonneau are provided with arm rests. The additional space inside the body adds to the comfort of the occupants without in any way spoiling the appearance, which is decidedly clean-cut, as may be seen from the illustration.

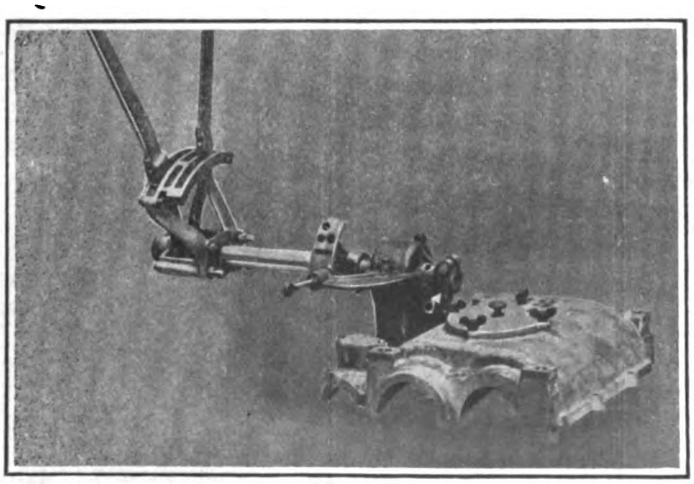

Fig. 11—View of the new change speed sector and gear shifting mechanism, including the interlocking device

An interesting point in the body design of the new models lies in the fact that the running boards have been cleaned and the battery box is now slung under the body, the tools having been placed in a compartment built into the apron.

The 66-Horsepower Model

Mention has already been made of the new motor in this model, and suffice it now to mention that the bore is 5 inches with a stroke of 7 inches.

Two features on all Pierce-Arrow models have been retained, viz., the seven-bearing crankshaft and the lubricating system with the tank placed above the cylinders in the manner shown in Fig. 9.

In the new model there will be used larger diameter live rear axle jackshafts with fluted ends for attaching to the driving wheels and compensating pinions. It will be possible in this model only to withdraw the live rear axle without taking the casing apart after withdrawing the hub and unscrewing the caps containing the bearing on the ends of the rear axle case. The brakes are 2 inches larger in diameter and the faces are 1-4 inch wider.

As in the other models the rear springs have been lengthened 4 inches. The radiators and hoods on all three models have been made higher, the "36" and the "48" being 1 1-2 inches and the "66" 1 inch higher than last year.

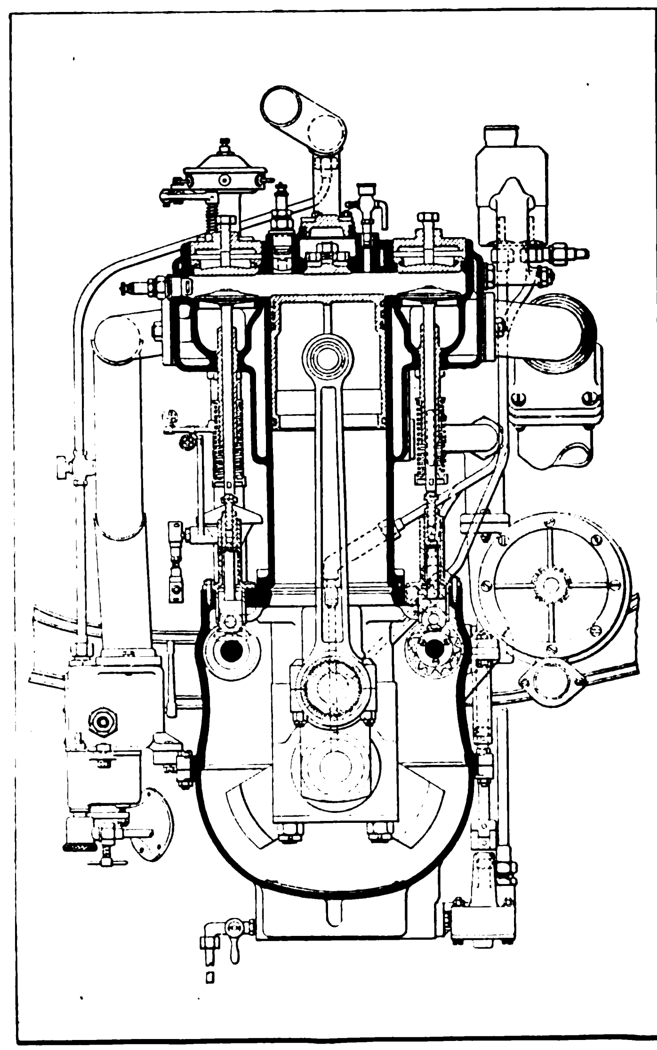

Fig. 12—Transverse section through the front cylinder of a Pierce-Arrow six-cylinder motor

Refinements of 1912 Locomobile

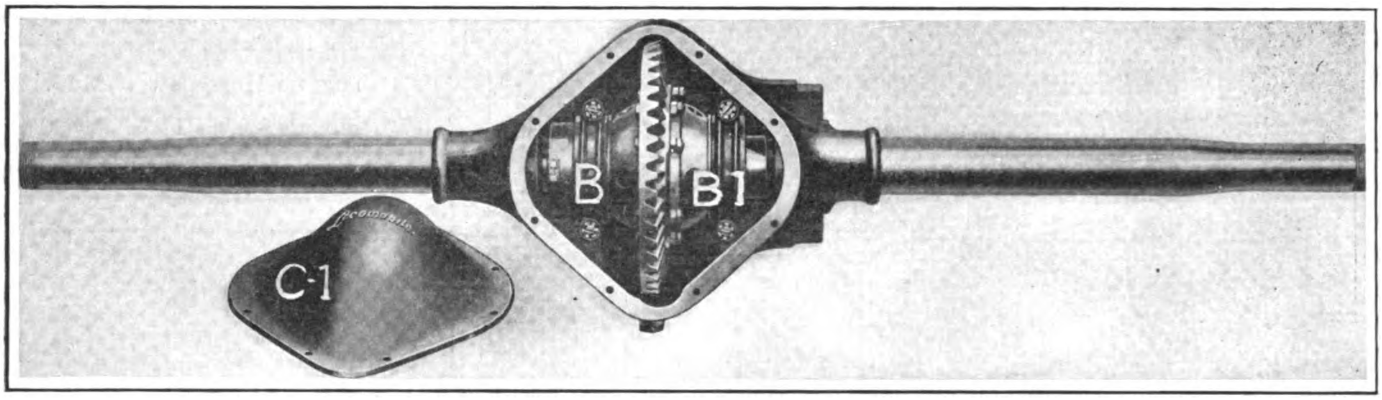

Fig. 1—View of the new live rear axle fitted to the Locomobile six with cover removed

WITH the exception of a few refinements, that would not be noticed by the casual observer, there has been no material difference in the new models of the Locomobile car, manufactured by the Locomobile Company of America, Bridgeport, Conn. The personal comfort of the occupants and the general appearance of the coachwork has received marked attention, with the result that the new models have been improved equally as regards the lines of the body, the interior finish and the upholstery.

To pass from the coachwork to the mechanical features of the car, the power plant of the 1912 Locomobile six differs but little from its predecessor. The same type of 4½ x 4½ T-head cylinders, cast in pairs, is used, and the motor, although rated at 48.6 horsepower, is claimed by the makers to develop somewhere in the neighborhood of 65 horsepower. The crankcase has been somewhat lengthened to accommodate slightly longer bearings for the pump and magneto shafts, and the attachment of the timing gears to their respective shafts has been modified. The magneto coupling has been enclosed in an aluminum cover to maintain a constant supply of grease to this part.

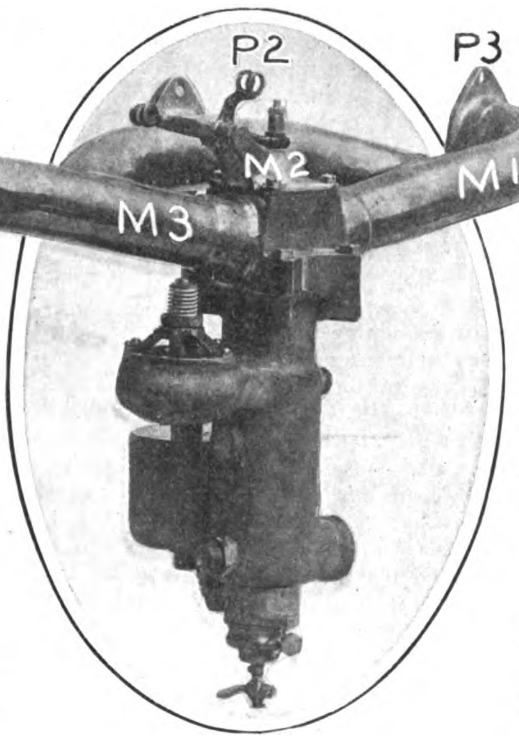

Fig. 2—General view of carbureter and manifold

The most radical change of a mechanical nature is to be found in the rear axle and differential housing. As before, the live axle is of the floating type, which serves only to turn the rear wheels, carrying no part of the load. The axle housing is now a one-piece steel casting. In former years this was a two-piece axle. In the new design shown in Fig. 1 the weight is carried upon a single casting, whereas the large opening at the rear, ordinarily covered with an aluminum cover C1, enables the differential to be easily reached. The bearings, that are mounted on the extremities of the cage, are held in position by strap bars B and B1, which are secured by four bolts. By

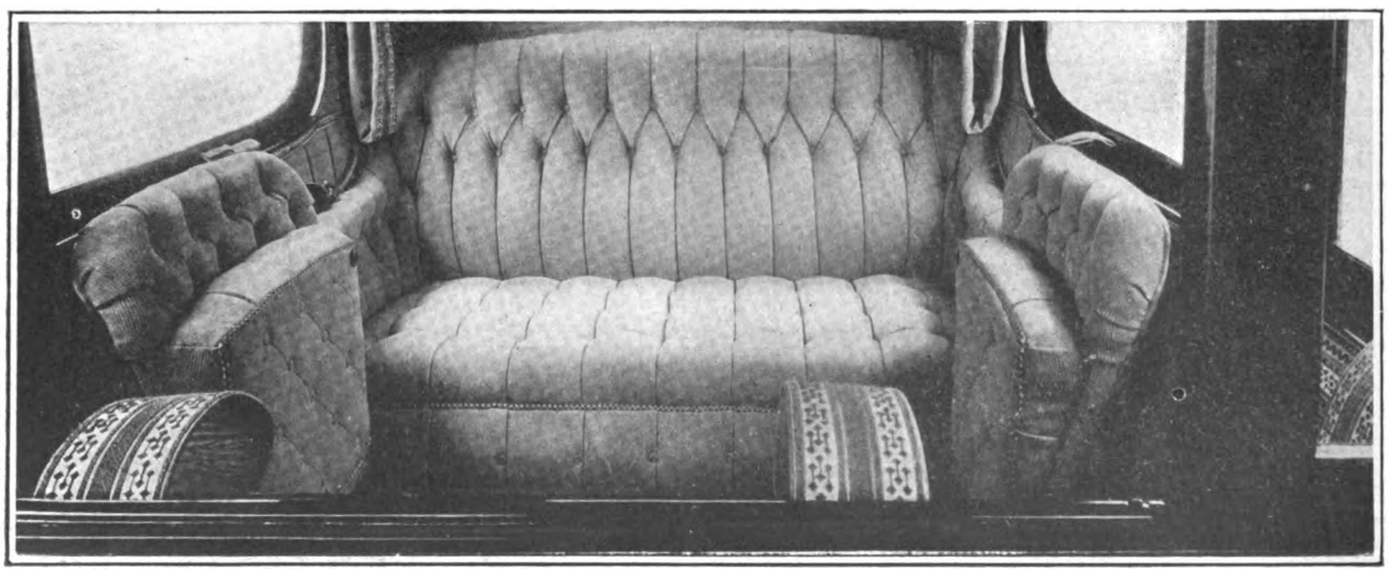

Fig. 3—View of the interior of the limousine, showing the upholstery and extra seats folded away

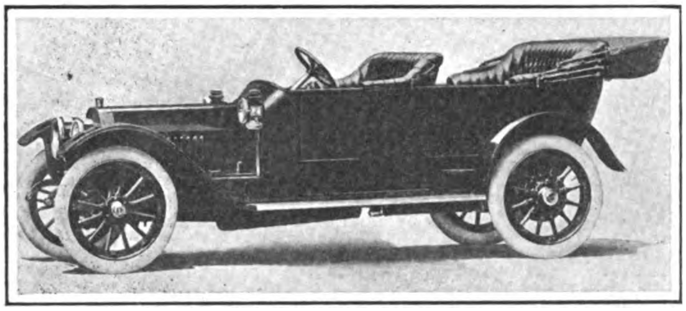

Fig. 4—Fore-door torpedo body to seat four passengers fitted to the Locombile six chassis

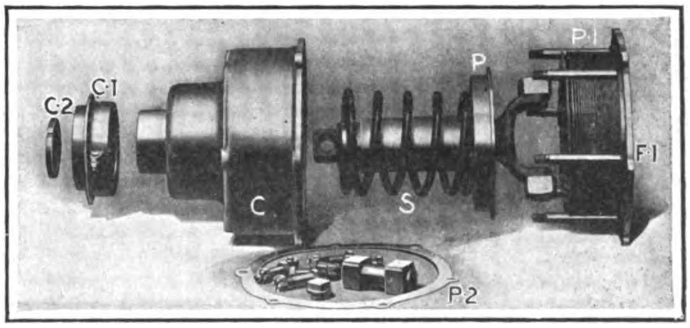

Fig. 5—Showing the various component parts constituting the Locomobile clutch

removing these bars the differential can be removed bodily from the casing after the axle driveshafts have been withdrawn sufficiently far through the axle tubes. Alloy steel tubes are pressed into the ends of the axle housing to form the weight-carrying portion of the dead axle. A pressure of several tons is used to force these into place, and rivets fasten tube and casing together.

The general appearance of both sides of the power plant of the six-cylinder motor can be obtained by referring to Figs. 13 and 14. Fig. 13 shows the exhaust side of the motor in which the exhaust manifold M is attached to a single port on each pair of cylinders. To heat the air before mixing with the gasoline an aluminum box B surrounds the manifold from which a pipe leads to the base of the carbureter. The water pump P takes the water from a large radiator placed in front of the motor and delivers it to two pipes P1 and P2. In order to maintain a steady flow to each pair of cylinders these pipes are attached to a central collecting pipe P3 so that the water passes to the cylinder bases W1, W2 and W3 at approximately the same pressure. One of the difficulties to be overcome in six-cylinder construction lies in the fact that each cylinder, or, as in the case of the Locomobile motor, each pair of cylinders, has to be fed equally both as regards cooling water and combustible mixture.

The use of spiral gears, made from chrome nickel steel, has been continued for the timing gear wheels, with a slight improvement in the method of attaching them to the ends of the camshafts. Owing to the fact that the teeth are not parallel with the axis, large spiral gears when run under load produce a slight end thrust on the bearings. In other words the angle of the teeth creates a resultant force which does not act in the plane of rotation of the gear. The method employed in the new models of the car under notice is to finish off the ends of the camshafts with large face plates flanged so as to coincide with corresponding recesses in the hubs of the gears. The gears are then attached to the flanges on the camshafts by means of four cap screws which have a continuous wire passing through holes drilled in the heads of each to prevent them from shifting as a result of the engine vibration.

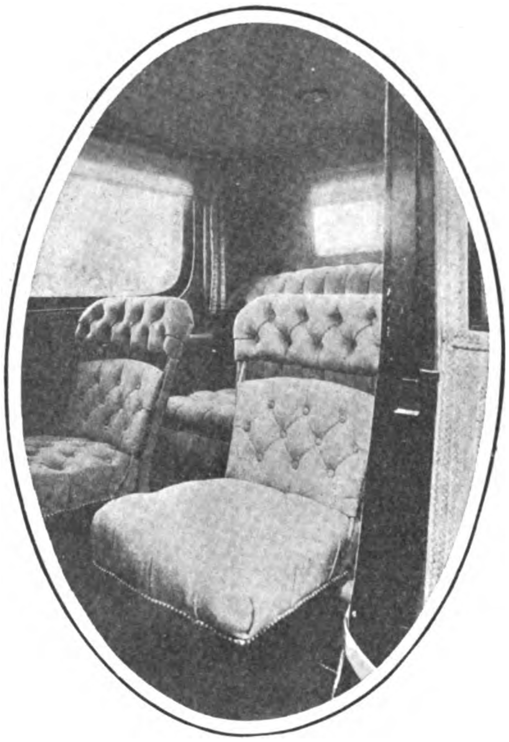

Fig. 6—View of the interior of the limousine, showing extra seats

The crankshaft is mounted on seven main bearings, B1, B2, B3, B4, B5, B6, B7, as may be seen by referring to Fig. 11, and the upper half of the crankcase which carries the bearings is made from rigid and heavy government manganese bronze, which is a feature of Locomobile construction. To the bottom of this crankcase is attached the aluminum pan shown in the lower half of Fig. 11. Therein is contained the main oil reservoir. A spiral gear at the rear end of the exhaust camshaft drives a vertical shaft which operates the rotary pump P4 in Fig. 13. The oil flows by gravity from the well in the motor to the pump,

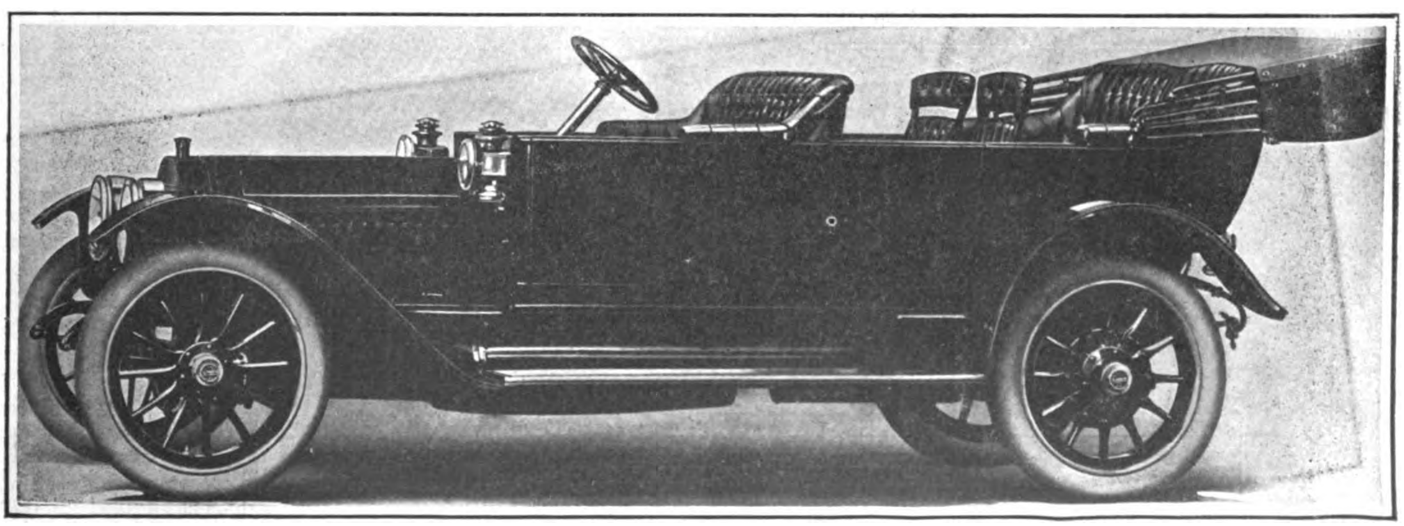

Fig. 7—General appearance of the new flush fore-door six-cylinder Locomobile seven-passenger touring body

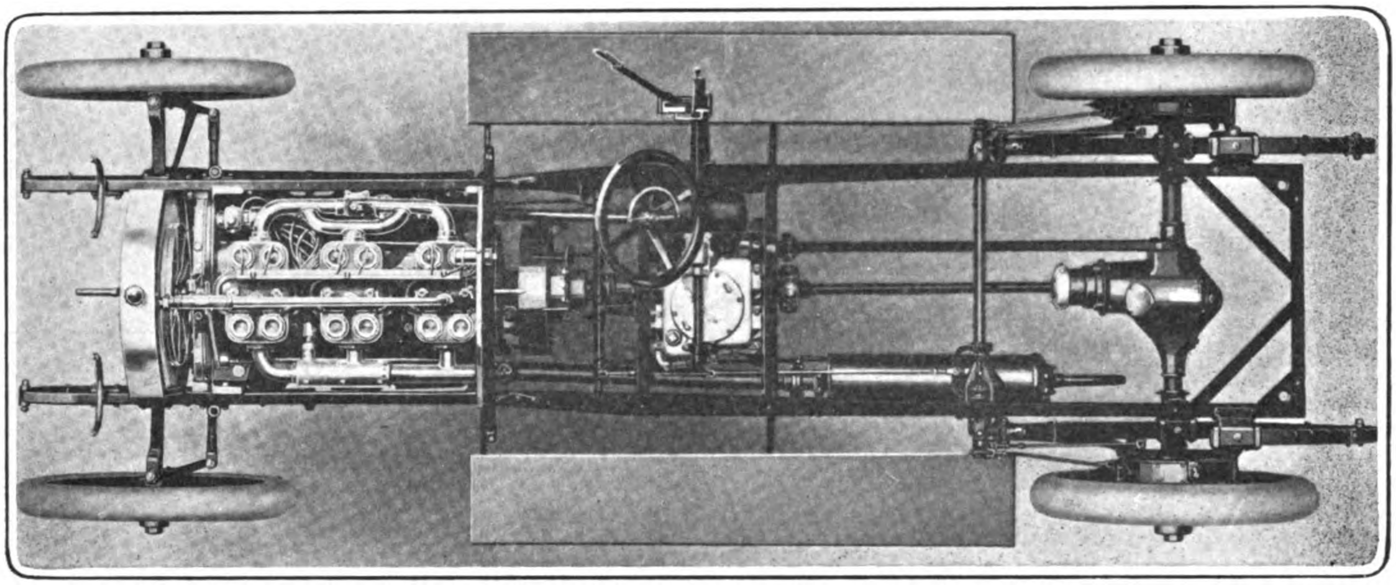

Fig. 8—Plan view of the Locomobile six, showing the arrangements of the various units

whence it is delivered under pressure to a T-connection. One end of this connection is attached to the main feed pipe O which passes along the side of the crankcase. Individual leads O1, O2, O3, O4 and O5, feed each crankshaft bearing as well as the camshaft bearings.

The second branch of the T connects with a pipe inside the base of the motor shown in Fig. 11, where the troughs T1, T2, T3, T4, T5 and T6, are situated. A hole in the oil feed-pipe keeps the troughs constantly filled with oil and the lower ends of the connecting rods being fitted with scoops, the oil is churned up sufficiently to lubricate the piston and cylinder. In order to prevent an undue amount of oil from reaching the cylinders, baffle plates are provided over the openings through which the connecting rods reciprocate. Inasmuch as the oil in each trough, into which the scoops dip, cannot exceed a certain depth, and as the baffle plates limit the size of opening through which the oil is sprayed, smoking troubles and their attendant consequences are minimized.

Part of the intake side of the motor is shown in Fig 14 from which it may be seen that the magneto rests upon a ledge cast integral with the upper part of the crankcase, and is held in position by means of a steel band and an easily removable connection. The coupling of the magneto in the new models is of the universal jaw-type as heretofore, but it is now encased in an aluminum covering which is packed with grease sufficient for a season's running. The leads to the sparkplugs are carried in the tube B and the method of attaching the intake manifold is also shown. The arm M3 leads to the rear pair of cylinders, and the lead M1 to the front pair. In order to equalize the flow the connecting arm of the manifold M2

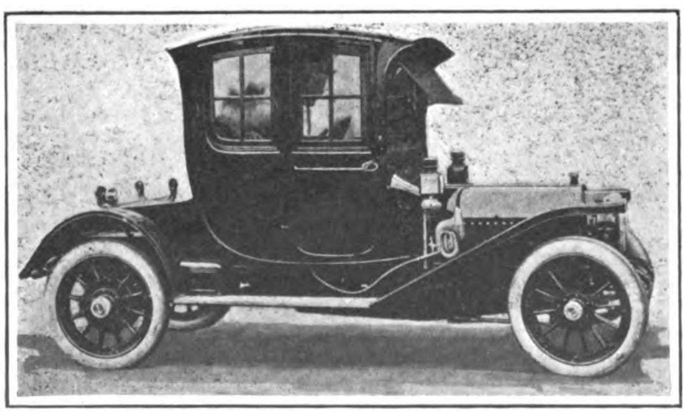

Fig. 9—Coupé body fitted to the Locomobile four

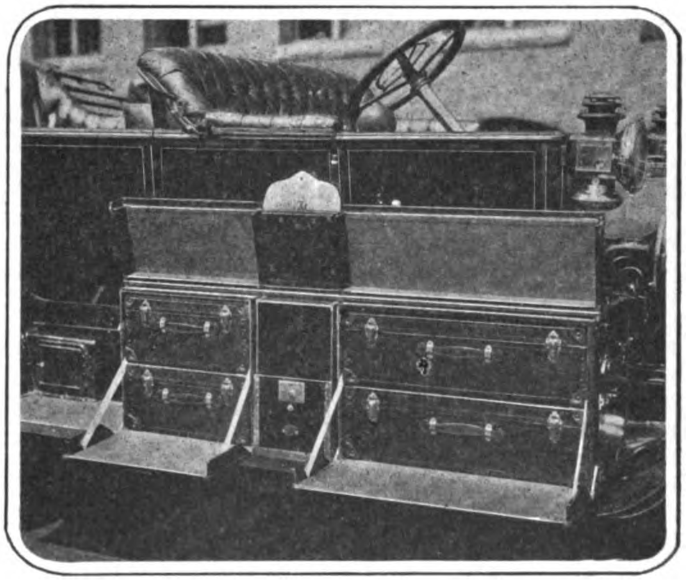

Fig. 10—Method of carrying baggage in waterproof-covered suit cases on the running boards

is attached midway in the forward and rearward arms and may be clearly seen in Fig. 2.

The carbureter, of the float-feed, constant-level type, employs a single tube through which passes the gasoline for all speeds of the motor; in other words, the functions of the needle valve and the auxiliary gasoline supply are performed by a single tube. In addition to the cone-shaped nozzle at the end, the pipe is perforated at the center of the strangling tube, and thus the supplementary openings for the low speeds are furnished.

The action of the auxiliary air valve V is simple and is controlled by a dashboard lever which serves as a convenient and efficient adjustment while the car is running. The action of the lever is to compress a second spring which opposes the action of the main spring so that the tension of the latter can be regulated to suit all conditions of weather. To assist the vaporization the mixing chamber is water-jacketed.

The gearset affording four ratios of gear is located amidships, and is of the selective type. Like the motor base the housing is of manganese bronze. The power of the motor is transmitted by means of a multiple-disc clutch, shown in Fig. 5, the flange F1 being attached to the mating boss on the flywheel. The pressure needed to keep the plates P1 and P2 together is furnished by the spring S, and the whole is enclosed by the cover C, the tension of the spring and the adjustment thereof being taken care of by the ring C2.

Two radius rods are attached at their rear ends by means of discs to the rear axle housing, forming covers for the brake drums, and at their forward extremities to the spring brackets. The torsion rod is of pressed steel mounted at the forward end in a vertical cylinder between two heavy springs. The combination of radius rods and torque member is intended to relieve the springs of pull and twist, permitting them to perform, unhindered, their work of supporting the weight of the car.

The suspension of the chassis is taken care of by semi-elliptic springs, at the front, 38 inches long and 2 inches wide, and at the rear by means of three-quarter elliptic springs 48 inches long and the same width as the front springs. When the car is loaded practically straight-line drive between the gearset and the differential obtains, as the propeller shaft revolves at an angle of about one degree with the crankshaft. Four universal joints are provided—two between the clutch and gearset and two between the gearset and live rear axle. The gasoline tank is situated below the driver's seat and has a capacity of 25 gallons. An auxiliary oil tank is placed alongside the gasoline tank and is provided with a shut-off cock.

The wheel base of the six is 135 inches, and the tires are 36 x 4 1-2 for the front, and 37 x 5 inches for the rear wheels, fitted to demountable rims.

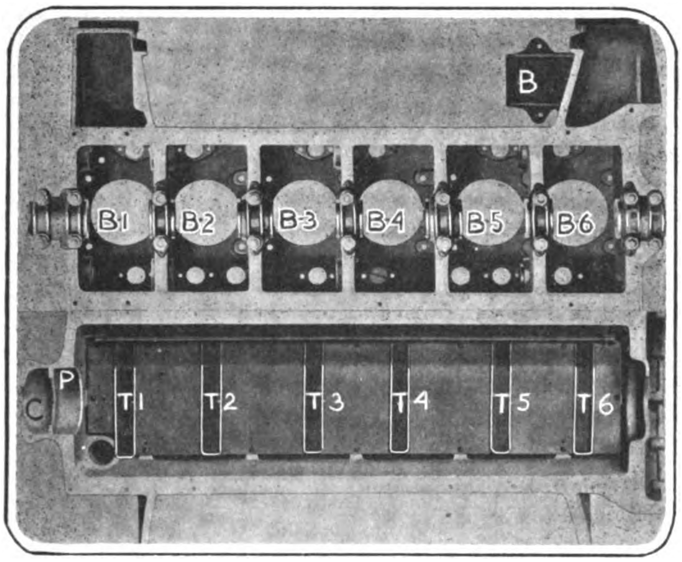

Fig. 11—Two views of the crankcase of the Locomobile six

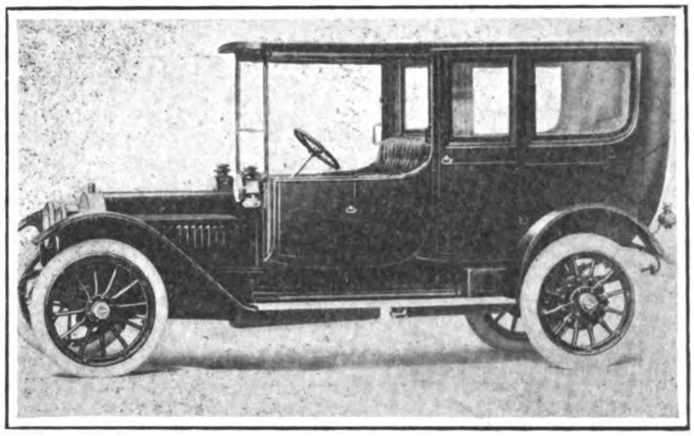

Fig. 12—View of the fore-door limousine fitted to a Locomobile six

Figs. 3 and 6 show the upholstery of the limousine, which has been made very luxurious, particular care having been paid to the folding seats in order to make them as comfortable as possible. It is better to pay more attention to the upholstery of a car and fit ample cushions, thus relieving the passengers from road shocks, than to fit "soft" springs and thereby weaken this vital organ. The cushions of the rear seats are 10 inches deep and there are three rows of 8-inch springs in each of the three sections composing the back. The back of the rear seat is two inches higher than that of the one in front, and neither projects more than five inches above the sides and doors that form a continuous straight line from dash to rear of tonneau. The concealed hinges on which all doors are mounted serve to keep the exterior of the body free from any metal projections that would tend to destroy the color scheme or symmetry of the outline of the car. The lock on each door is operated only by means of a top lever, handles being thus eliminated from the outer surface of the body.

The running boards have been kept clear of all equipment or attachments. This has been brought about by carrying the two spare tires at the rear of the body, held in place by brackets against the back of the tonneau; by stowing the tools and battery under the floor boards at the back; and by placing the gasoline tank under the front seat. This arrangement not only adds greatly to the appearance of the car, but leaves the running boards, which are unusually long and commodious, free to carry such suit cases, trunks, or other baggage as may be required by the members of the touring party.

Automobile Scores in British Strike

LONDON, Sept. 6—The past fortnight has witnessed England disturbed in every quarter by the labor struggle—the carefully planned strike of railroad and transport workers which was calculated to disorganize every trade and thereby to hasten along the granting of the men's full demands. Unfortunately for the strike-leaders, they had forgotten to take into account the development of the automobile, and hence, in great measure, came the failure of their schemes. Now that the trouble is all over, it is consoling to reflect on the beenfits that have accrued, to the public, in that the railway monopoly has been proved to be unimportant, and to the automobile industry, in that the value of the commercial vehicle has been demonstrated in the most thorough manner conceivable. Already, the results are showing themselves in a steady rush of orders from transport companies and from traders of all classes for trucks, vans and haulage tractors.

Undoubtedly, the strikers scored well at first, for the shortness of the warning notice caught the motor vehicle owners unprepared and the gasoline supplies were at a low ebb. However, within a week the motor services were in full swing, and, by dint of careful management, the fuel was made to last. At the first signs of the outbreak, the available reserves were bought up by the omnibus and transport concerns, and the main sufferers were thus the pleasure car and small van owners. As much as $2.50 per gallon was regularly charged for gasoline at certain places, instead of the usual 25 cents, and resort had frequently to be made to kerosene, naphtha, alcohol and other possible, though undesirable, fuels. Here is another lesson which has been learned; everyone is now storing gasoline reserve supplies, and in case of further labor troubles or a war outbreak, there will be sufficient motive fuel for six months running.

A week before the railway stoppage commenced, the London carters ceased work, and they expected to paralyze the trade of the metropolis by their action. They were making a big mistake, for, at all the markets, the lumbering two-horse wagons were at once replaced by swift-moving motorvans, private cars, motorcycles and trailers, and, in short, every conceivable type of power vehicle. The work was carried on without any delay. The speed limit was abolished by general consent and it was possible to average over twenty-five miles an hour right through London. Under ordinary conditions, with the obstruction of horse-drawn vehicles, the speed would be little better than half. London has had its first experience of purely mechanical traffic, and so universally satisfactory have been the results that serious proposals are afoot for the limitation of the use of horsed vans and wagons to the evening and night hours.

Still another use for the automobile was found in Liverpool, where riotous happenings were experienced. Both the police and the military were severely damaged by the missiles—bricks, bottles and occasional bars of iron—thrown by the hooligans from the shelter of houses on the line of march. Accordingly, half a dozen three-ton goods trucks were equipped with substantial sides and tops of wood barricading, the radiator and all vulnerable parts were cased in, and these armored wagons then patrolled the disaffected areas with armed men on board. Quite a useful purpose was served by these vehicles, which were able to convey the majesty of the law right through the mob to the center of all disturbances, and yet to protect the police from cowardly assaults from the housetops.

Few as were the special road services instituted during the strike, they all, without exception, proved their utility in a remarkable way, demonstrating to the general public that, in a country like England, where 200 miles is almost the longest normal journey for goods traffic, the power wagon and the road train can compete openly with the railway service.

To transport food supplies and perishable goods from the bases of supply to the distributing centers at a time of need would require at least ten or fifteen thousand motor vehicles. Such a number of trucks and lorries could not be mustered together and a proposal has therefore been brought forward, by Lord Montague, that *motorists should combine together in a big public service league, which would be so organized that when the time came, a sufficiency of cars and drivers would be available to meet any emergency.* The two British Clubs—the R. A. C. and the Automobile Union—have a membership of 50,000 *between them, and there would probably be not much difficulty in enrolling the required number of patriotic car owners.*

The strike has proved a godsend to the commercial motor vehicle industry, and all the well-known manufacturing firms are now booked right up for at least six months to come. Meanwhile, inquiries are pouring in and there is clearly enough available business to keep the whole of the trade well employed for a year or two to come.

As the existing firms are all fully occupied, the pleasure car manufacturers are hurriedly completing the plans which they have for several seasons been developing and the majority of the most important touring car firms will have their commercial vehicle section fully working by the Spring time. The one, three, and five-ton trucks are the popular fancies; the small pneumatic-tire van business is only attempted in a desultory sort of way—generally as a means of using up last year's pleasure car chassis. In this section, right away, there seems quite a good opening for the American manufacturer. Incidentally, it is interesting to note the comparative sales figures of commercial vehicle progress, obtained by one of the technical weeklies by confidential reports from the manufacturers. Taking the 1905 output as a basis with 100 as the figure, the 1907 figure is 201; by 1909 it slowly had increased to 315, while the estimated total for this present season is 620. Next year, according to the present outlook, should give a figure well over the 1,000 mark.

Alco Rests on Its Laurels

The following self-explanatory statement has been issued by the American Locomotive Company:

"The American Locomotive Company has decided to withdraw from racing. Our reason for this action is that racing takes more time and attention on the part of our organization than we feel justified in devoting to it.

"This decision will not apply to commercial vehicles if properly arranged contests for such are planned in the future.

"The six-cylinder stock car with which Mr. Grant won the last two Vanderbilt Cup races has been presented to him by the company as an expression of our appreciation of his services to us."

Wilby Reaches Chicago

CHICAGO, Sept. 11—Thomas W. Wilby, driving an Ohio car, who is on a 12,000-mile pathfinding tour in the interests of the Office of Public Roads of the Department of Agriculture at Washington and the Touring Club of America, reached Chicago Saturday, having come from New York. Reporting on the first leg of the journey, Mr. Wilby says: "As for the eastern section of the transcontinental route, I found that New York State is macadamizing the whole of the Albany post road and the Mohawk Valley route. When completed they will make a fine system of highways. Ohio hasn't done much yet with its gravel highways, and we found very little macadam in Indiana, but the last-named State has some wonderfully straight, broad gravel roads, extending for miles across the level prairie-like country. They would make ideal highways at very little expense and trouble. Indiana certainly would confer a public boon upon motorists if it would put its road-making machines into operation. We were surprised to find what were little more than sandy trails near Michigan City on the way into Chicago."

Grand Rapids' Motor Fire Equipment

GRAND RAPIDS, MICH., Sept. 9—Following its general policy of substituting motor-driven fire apparatus for the old style pulled by horses, the Board of Police and Fire Commissioners has awarded the contract for a new auto hosecart to the Seagrave Company, of Columbus, Ohio. The new machine is to cost $3,950 and will be stationed at the new No. 12 engine house. The Michigan Hearse and Carriage Company of this city now is engaged in constructing the bodies for two chemical automobile machines to be installed at No. 1 and 3 engine houses. At No. 5 engine house there is a combination chemical hosecart and truck, Battalion Chief Walker has an official runabout and the board is figuring on letting a contract for a hook-and-ladder truck. It is the policy of the board to purchase the chassis from the automobile manufacturer and then have the body made in this city according to specifications made by the board. The police department at present has a motor-driven ambulance and patrol.

See Pickens' Hand at Kansas City

According to officials of the Contest Board of A. A. A., the race meeting hitherto sanctioned for Kansas City, September 16-17, was declared off for rather a different reason than the one announced. It was said that the track was in impossible shape for racing and that the reason for withdrawing the sanction was founded in that fact. It is now stated with some show of authority that the redoubtable "Bill" Pickens was the actual promoter of the meeting, using the name and personality of some person who was not in the bad graces of the authorities. It is further stated that one or more of the racing cars owned or controlled by Pickens are being held on attachment in Kansas City because of certain preliminary obligations of a financial nature alleged to have been contracted by the promoter.

Pickens is quoted as saying that he had no intention of actually holding a race meeting, but merely wanted to show the public that he could get a sanction from A. A. A. The action of that body shows that "Bill" was wrong.

New Homes for Everitt and Oakland

Announcement has been made that the Shepherd Motor Car Company which has handled the Oakland line in New York for several years, has taken on the Everitt. The full line of the Metzger company's production will be handled in the way of passenger vehicles and the new six-cylinder creation of the company will be on hand within two weeks.

The Oakland cars will be sold in New York by a factory branch which will be installed about October 1. The branch will be located on Broadway near the salesrooms of the Shepherd company.

Riess Company to Move North on Row

C. E. Riess & Co., handling the Marion and American lines, will remove to the quarters formerly occupied by the New York branch of the Thomas at Sixty-third and Broadway. The change will be accomplished about October 1. Business has been extraordinarily good for the type of cars represented by the Marion during the past season, and the 1911 allotment has been oversold. Mr. Riess personally is at the factory trying to secure another shipment of cars.

Calendar of Coming Events

Shows, Meetings, Etc.

Sept. 25-30.........Atlantic City, N. J., Convention and Exhibition of the Carriage Builders' National Association.
Jan. 1-5, 1912......New York City, Grand Central Palace, Annual Show, Automobile Manufacturers' Association of America.
Jan. 6-13...........New York City, Madison Square Garden, Twelfth Annual Show, Pleasure Car Division, Automobile Board of Trade.
Jan. 10-17..........New York City, Madison Square Garden, Annual Show, Motor and Accessories Manufacturers.
Jan. 10-17..........New York City, Grand Central Palace, Twelfth Annual Show, National Association of Automobile Manufacturers.
Jan. 15-20..........New York City, Madison Square Garden, Twelfth Annual Show, Commercial Division, Automobile Board of Trade.
Jan. 18-20.........New York City, Annual Meeting of the Society of Automobile Engineers.
Jan. 27-Feb. 10....Chicago Coliseum, Eleventh Annual Automobile Show under the auspices of the National Association of Automobile Manufacturers. Pleasure cars, first week. Commercial vehicles, second week. Accessories, both weeks.
March 2-9.........Boston, Mass., Tenth Annual Show, Boston Automobile Dealers' Association, Inc.

Race Meets, Runs, Hill-Climbs, Etc.

Sept. 12-15........Omaha, Neb., Third Annual Endurance Run, Omaha Motor Club.
Sept. 15............Knoxville, Tenn., Track Races, Appalachian Exposition.
Sept. 16............Syracuse, N. Y., Track Races, Automobile Club and Dealers.
Sept. 18-20........Chicago, Ill., Commercial Reliability Run, Chicago Motor Club.
Sept. 19............Burlington, Vt., Reliability Run, Merchants' Protective Association.
Sept. 23............Philadelphia (Point Breeze), Track Races, Philadelphia Automobile Trade Association.
Sept. 23-25........Detroit, Mich., Track Races, Michigan State Agricultural Society.
Sept. 30............Guttenburg, N. J., Track Races.
Sept. ....Steubenville O., Hill Climb, Automobile Club of Jefferson County.
Sept. ....Denver, Col., Track Races, Denver Motor Club.
Oct. 6-13..........Chicago, Ill. Thousand-Mile Reliability Run, Chicago Motor Club.
Oct. 7..............Danbury, Conn., Track Races, Danbury Agricultural Society.
Oct. 7..............Philadelphia, Fairmount Park Road Races, Quaker City Motor Club.
Oct. 7..............Springfield, Ill., Track Races, Springfield Automobile Club.
Oct. 13-14.........Atlanta, Ga., Track Races.
Oct. 14.............Santa Monica, Cal., Road Races.
Oct. 14 (to 25)....New York City, Start of the Annual Glidden Tour, en route for Jacksonville, Fla.
Oct. 16-18.........Harrisburg, Pa., Reliability Run, Motor Club of Harrisburg.
Nov. 1.............Waco, Tex., Track Races, Waco Auto Club.
Nov. 2-4...........Philadelphia, Reliability Run, Quaker City Motor Club.
Nov. 4-6...........Los Angeles,-Phoenix Road Race, Maricopa Auto Club.
Nov. 9.............Phoenix, Ariz., Track Races, Maricopa Automobile Club.
Nov. 9, 10, 12.... San Antonio, Tex., Track Races, San Antonio Auto Club.
Nov. 27............Savannah, Ga., Vanderbilt Cup Race, Savannah Automobile Club.
Nov. 30............Los Angeles, Cal., Track Races, Motordrome.
Nov. 30............Savannah, Ga., Grand Prize Race, Savannah Automobile Club.
Nov. ....Columbia, S. C., Track Races, Automobile Club of Columbia.
Dec. 25-26.........Los Angeles, Cal., Track Races, Motordrome.

Foreign Fixtures

Sept. 10-20........Hungarian Small-Car Trials.
Sept. 16...........Russian Touring Car Competition, St. Petersburg to Sebastopol.
Sept. 17...........Semmering, Austria, Hill Climb.
Sept. 17...........Start of the Annual Trials Under Auspices of *l'Auto*, France.
Nov. 3.............London, Eng., Olympia Show.

The Winter Automobile

MORE attention is being paid among automobile makers this fall to the winter body than ever before. Some years ago many automobile makers built nothing but open touring or runabout bodies. Then a demand grew for an enclosed type, and the limousine came into being. This was soon followed by the landaulet, which came as a combination open-closed type. Following this came the coupé. At present much attention is being bestowed on a special type of enclosed car for the owner-driver who wants to sit at the steering wheel himself for his winter trips, but who does not want to be separated from his family by a plate glass partition. The demand for this style of car will be a most appetizing one in a year or so. Such a car type is the limousine for the middleman, the owner who does not want a chauffeur, but who wants to take his family to the theatre, to church or for an outing. The body is a one-compartment type, with room between the two front seats for a passage to said seats.

The chief objection in the past to this type of body has been the entrance to the front seats. It has demanded a double set of doors—one for the front seats, the other for the back seat. This has been expensive, too expensive to be exploited in the medium-price field. The solution has been in the wider body for the front seats. Some builders are making the body at this point as wide as the tonneau at the rear. This has been made possible by adding body plates which project out from the frame members at each side and on which the body rests. This extra width allows of two wide front seats with a good passage between them. With this design but two doors are customary, but one only is actually essential; it should be on the right side, as in all the larger cities the traffic ordinances require a vehicle to stop with the right side to the curb.

With modern body constructions every possibility in the way of individuality of seating is obtainable in a one-compartment winter body. The interior arrangements depend entirely on the owner's requirements. Small supplementary seats for children can be located in almost any part of the compartment. A common practice is to arrange one folding seat at the left end of the dash, where ordinarily there is plenty of room for it.

One detail overlooked in many winter cars is the heating arrangements. No provision is made for heat in the majority of the types, and in cold weather it is necessary to use heaters which are placed on the floor. These are good; but, in addition to them, there is no reason why a part of the exhaust cannot be utilized for this work. The automobile is a heat machine; the engine must keep very warm to work well. At present much of this heat goes off through the muffler, and a portion could be used to keep the compartment at any desired temperature. Some makers have put small exhaust radiators in the car floor; others have hot-air-jacketed a part of the muffler and led the air through this jacket before getting it into the compartment. All are good, yet it seems that the good work has not been carried far enough. The man buying an enclosed winter car for $2,000 or less wants a little heat as well as the owner in his $4,500 limousine. The extra cost has not been the prohibition; rather it has been the fact that the maker has not done it. He has reasoned that it has not been demanded, and then why should he install it? This is short-sighted logic; it is the same logic that some makers used in conjunction with the fore-door body; they did not install it until demanded and then found out that they were six months behind the times. In heating winter bodies, the car maker should keep up with the times, and if he errs let him err in being ahead of the times rather than in being in the rear.

It is not entirely with enclosed cars that the critic sees the comforts of the car owner being looked after more than ever in the 1912 cars. Many makers have taken up the matter in open touring cars and runabouts. Not a few factories have enhanced the luxuriousness of the upholstery almost 100 per cent. for the coming season. This administers directly to the comfort of the owner and his family. The upholstery has been inadequate on many cars; it has sufficed at the start, but soon became hard.

There is yet much room for improvement in the comfort-administering details of the car body. Who has not ridden in the rear seat of a seven-passenger car and had his legs cramped in order to get his feet on the inside or on the outside of the supports for the extra seats? It frequently happens that if the passenger sits at the right end of the rear seat he has to constantly cramp his feet to the inside of the auxiliary seat rest, whether the seat is folded away at the side of the tonneau or in use. If the designer of the seat would take a 100-mile ride some day in such a car he would immediately get back to the factory to design a rational extra tonneau seat. In other cases the extra seat is so close to the rear seat that the rear-seat passengers have not room enough and their shins are constantly rubbing against the back line of the extra seat. This is equally bad and it is astonishing that body designers will allow such body jobs to be sold to the public. It is almost a certainty that the designer has never taken a long trip in such a seat. It may be argued that such seats are not intended for long trips, but any man with experience in long-distance touring will agree that it is more comfortable to ride all day in a comfortable extra tonneau seat than it is in the tonneau seat itself.

Gossip of the Coming Shows

ALLOTMENTS of space at all the shows sanctioned by the Motor and Accessory Manufacturers will be made October 7 when that organization assembles in New York. The M. & A. M. has sanctioned the Garden Show of the A. B. of T.; the Palace Show of the N. A. A. M.; Boston pleasure and commercial shows and the Chicago National Show.

The organization now has 222 members and has on file about a score of applications for membership. It is expected that practically 150 of these concerns will have space at the New York shows and about the same number at Chicago. The Boston shows always have a large number of locally made accessories that are not shown elsewhere, but the indications are that there will not be more than 150 M. & A. M. concerns there.

Drastic action against independent manufacturers who have exhibited at unsanctioned shows in the past has not been contemplated and in fact the independents will have a chance to exhibit their wares at the big shows.

The basement of the Garden will be used largely by exhibitors who are not members of the M. & A. M. and there will also be some space in the galleries for such concerns. There is no reason why those who have exhibited at unsanctioned shows may not take advantage of the open-door attitude that exists among the authorities.

While the drawings for space have been made as far as the A. B. of T. show are concerned, there are so many alterations to be made in the interior arrangement of the Garden that there may be a number of changes in spaces. This matter is now in the hands of the architects and the final arrangement may not be absolutely fixed for several weeks.

The drawing for space for the Palace Show will take place October 4. It is predicted that this affair will prove the largest and most complete automobile exhibition ever held under the designation "Palace Show."

The independents who exhibited at the unsanctioned show last year are eligible for reinstatement or have been reinstated and several of the more prominent companies that took part have applied for space. The rule of the N. A. A. M. was that suspension for 18 months must follow violation of the rule against participation in unsanctioned events, but this rule has been so modified that nobody shall be barred.

The show contemplated by the Automobile Manufacturers' Association of America, and which was tentatively scheduled for the Palace, is shrouded in some uncertainty. Secretary Longendyke and the association have offices at Forty-fourth street and Fifth avenue, but on Tuesday noon, when a representative of THE AUTOMOBILE called there, the door was locked and the elevator starter imparted the information that Mr. Longendyke was out of town.

Nothing definite has been announced recently about the show and it is pretty widely rumored that the original date for holding it has been postponed. In the absence of Mr. Longendyke this could not be confirmed.

It is freely predicted that the show season of 1912 will be larger and better than any of its predecessors.

New N.A.A.M. Members

AT its recent meeting the N. A. A. M. elected the following to membership:

J. I. Hanley, representing American Motors Company, Indianapolis, Ind.

G. A. Matthews, representing Jackson Auto Company, Jackson, Mich.

C. H. Walters, representing DeTamble Motors Company, Anderson, Ind.

F. H. Dodge, representing Ohio Electric Car Company, Toledo, Ohio.

A. B. C. Hardy, representing Marquette Motor Company, Saginaw, Mich.

George E. Daniels, representing Oakland Motor Car Company, Pontiac, Mich.

T. A. Campbell, representing Imperial Auto Company, Jackson, Mich.

T. F. Hart, representing Inter-State Automobile Company, Muncie, Ind.

Charles D. Hastings, representing Hupp Motor Car Company, Detroit.

D. A. Shaw, representing Simplex Motor Car Company, Mishawaka, Ind.

W. J. Groves, representing Mack Bros., Motor Car Company, Allentown, Pa.

Fred W. Haines, Regal Motor Car Company, Detroit, Mich.

R. C. Hupp, representing Hupp Corporation, Detroit, Mich.

Rauch & Lang Carriage Company, Cleveland, Ohio.

Thomas Henderson, vice-president of the Winton Motor Carriage Company has resigned as a member of the Executive Committee of the N. A. A. M. Charles W. Churchill was elected in place of Mr. Henderson. Suitable resolutions of regret were ordered engrossed and spread upon the minutes of the organization and Mr. Henderson was unanimously chosen to be an honorary member of the committee.

To Test License Right

REGARDING the basic principles involved in licensing of automobiles, the N. A. A. M. has issued the following official statement with regard to its intentions to have the legal status established:

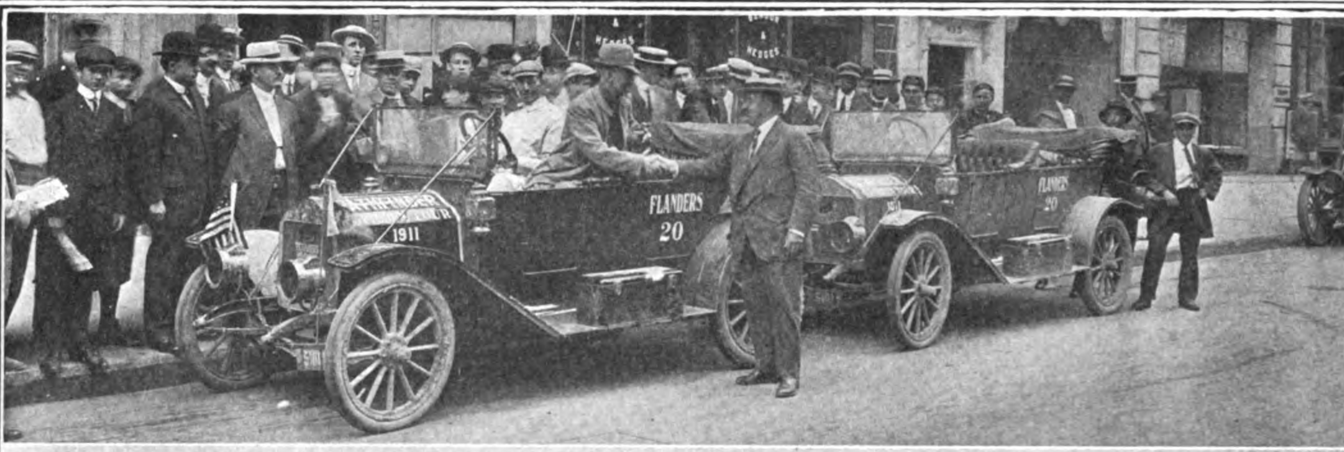
"It was decided that what has been known as the New Jersey Test case shall be carried to the Supreme Court of the United States. This is a case instituted five years ago, designed to show that no State or any other power may constitutionally demand that an automobilist take out a license. The case was started in the lower courts and has progressed step by step, the decision in each case being adverse. This was expected, and indeed hoped for, so that the question might, in due course, reach the highest court."

M. C. A. Defines Grade 4 Contests

When the Active Rules Committee of the M. C. A. met last week it was decided to amend the contest rules so that the Glidden Tour this fall could be entered with other than registered stock models. At the Detroit meeting of the M. C. A. a resolution was recommended to widen the field for Grade 4 contests by making registration unnecessary in that grade on and after January 1, 1912. The recent action of the Rules Committee merely advances the date of the rule's operation.

Winter Show for Worcester

WORCESTER, MASS., Sept. 11—Owing to the success of the Licensed Dealers' show, recently held in this city, arrangements are being made to hold a larger and more complete exhibition in the Worcester Auditorium during the coming Winter. A feature of the recent show, which was held under tents at the New England fair, was the exhibit of commercial vehicles, given in a specially constructed tent.



NEWS OF THE WEEK CONDENSED

Start of the Flanders 20 Glidden Pathfinder from New York City en route for Jacksonville, Fla.

NEW YORK—The practicability of inter-city trucking service was demonstrated recently by the run which a brand new Commer truck made from Brooklyn to Philadelphia. The fully loaded Commer left Brooklyn at midnight, September 6, and arrived at its destination at 9 in the morning, two stops being made on the way. The average running time was 14 miles per hour.

MILWAUKEE, WIS.—A. McNeil, 161 Michigan street, has been appointed distributor of the Liberty Brush.

SHEBOYGAN, WIS.—The Erie Garage Company has been appointed district agent for the Hupp-Yeats electric line.

GRAND RAPIDS, MICH.—The name of the Buick Sales Company has been changed to the Grand Rapids Auto Company.

PORTLAND, ORE.—E. W. Vogler, president of the Northwest Auto Company, Portland, has added another agency to his long list. His latest acquisition is the Stearns.

SPOKANE, WASH.—Vance Wolverton, C. E. Lane and J. A. Munson are associated in the Spokane Everitt Motor Company, the latest invader of Spokane's auto row.

SACRAMENTO, CAL.—The city of Sacramento, Cal., has purchased two motor cars for use in its fire department service. This makes five purchased by that city in the last four years.

SPOKANE, WASH.—Harry Olive, formerly connected with Norman Church, the Southern California Stoddard-Dayton distributor, will hereafter handle the Overland cars in Spokane, Wash.

SYRACUSE, N. Y.—J. A. Seitz, head of the Abbott-Detroit agency in Syracuse, is having a large new building put up, corner Jefferson and Warren streets. He will move into this about December 1.

SAN FRANCISCO, CAL.—The U. S. Tire Company has opened temporary quarters at 414 Van Ness avenue, San Francisco. A new building is being erected for this company at 636-646 Van Ness avenue.

BOSTON, MASS.—Stanley G. Martin is now in charge of the Decatur truck branch in Boston, and he has had the business moved to the new maintenance department the company has opened in Cambridge.

BOSTON, MASS.—Arthur G. Johnson, formerly with D. P. Nichols & Co. when it handled the Frayer Miller trucks, is now sales manager of the Eastern Motor Truck Company, distributors for the Kelly truck.

MILWAUKEE, WIS.—An ordinance has been passed by the Common Council of this city forbidding the practice of cutting out the muffler in the city limits. The penalty for violation is a fine of $25.

MILWAUKEE, WIS.—The Franklin Auto & Supply Company, 321-323 Fourth street, agent for the Franklin and Regal, has been appointed State agent for the Curtis, Farman and Bleriot type of aeroplanes.

BOSTON, MASS.—The Hollander Automobile Company has opened salesrooms at 169 Huntington avenue, where it is handling the Metz car, made in Waltham. The local agency has the New England field for this make.

COLUMBUS, OHIO—J. B. Hoover, who has been operating a stamping works and machine shop at 619-621 North High street, has taken the Central Ohio agency for the Nyburg automobiles, manufactured in Anderson, Ind.

LOS ANGELES, CAL.—John W. Swan, who for the past three years has been connected with the Leon Shettler Company, of Los Angeles, has taken the position of sales manager for the Reo Pacific Company in San Francisco.

YORK, PA.—W. Archie Miller, West Market street, has opened an automobile garage and repair shop in the brick building at 308 West Mason avenue. Mr. Miller was formerly employed by the Snyder Auto Company, this city.

DELAWARE, OHIO—D. F. Boston, of Bowling Green, Ohio, has opened a vulcanizing plant in the Pickering block. Boston had been conducting a similar business in Bowling Green, but sold out to open the shop in Delaware.

GRAND RAPIDS, MICH.—A new fireproof garage has just been completed at 249 Lake avenue for Ed. Mosher. The basement is fully equipped for repair work, while the first and second stories will be used almost exclusively for storage.

COLUMBUS, OHIO—The Main estate has begun the construction of a large garage in the rear of the Neil House, Columbus, Ohio, which will be leased to an operating company to be announced later. The garage will be 63 x 96 feet.

COLUMBUS, OHIO—H. R. Leach & Co., located in the Exchange Building on Taylor avenue, have taken the Central Ohio agency for the Lambert friction transmission trucks, manufactured by the Buckeye Manufacturing Company, of Anderson, Ind.

SAN FRANCISCO, CAL.—Two more new cars are to be represented in San Francisco. The Pathfinder and Parry are the new entries in the California field. They will be handled in San Francisco by the Motor Car Manufacturers' Sales Agency.

TOLEDO, OHIO.—H. P. Robinson, of Toledo, has been placed in charge of the general agency of the Packard Motor Truck Company, with headquarters at Milwaukee, Wis. He was formerly connected with the New Era Paint & Varnish Company, of Toledo.

York, Pa.—Bids for the manufacture of the State automob.le license tags will be opened on September 19 by the State Highway Commissioner. Close to 42,000 tags have been issued this year and it is estimated that fully 50,000 will be required for next year.

Bristol, Conn.—The New Departure Manufacturing Company is sending out to all those who desire data sheets regarding ball bearings. The sheets also include stress tables and diagrams and are of such size that they can be inserted in the S. A. E. handbook.

Columbus, Ohio—A contract has been made with the Ford Automobile Company to rent five of its runabouts to mail collectors of Columbus, Ohio, for the purpose of collecting mails. The cars will be placed in service as soon as they can be properly equipped and manned.

Milwaukee, Wis.—The Stegeman Motor Car Company has appointed the Schreiber Motor Car Company, 180 Fifth street, as Western distributor and local representative. The company builds a line of trucks from one to six tons capacity, with a guarantee of 25 per cent. overload.

Fostoria, Ohio.—Henry J. Adams and four other members of his family, including two children of two and four years of age, encircled Lake Michigan in a Reo, 1911 car. Their trip of 1,700 miles has just been completed and the whole party of five greatly enjoyed the unique experience.

Toledo, Ohio—The McLeary Engineering Company, of Toledo, has closed a deal which gives it the exclusive selling rights in Toledo territory on the Mais motor vehicle. X. D. Johnson, formerly with the Croxton-Keeton Company, will have charge of the automobile department of the company.

Philadelphia, Pa.—A. M. Pearson, of this city, will soon assume the management of the St. Louis Franklin branch. Mr. Pearson originally handled the truck business of the Packard Motor Car Company, of this city, and was later manager of the truck department of the White Company in Boston.

Grand Rapids, Mich.—Since Messrs. Stratton & White have decided to handle the Hudson as well as the White cars, they have changed the name of the concern from the White Motor Company to the Stratton & White Auto Company. The entire floor space will be devoted to the storage of cars.

Indianapolis, Ind.—A. E. Creeger, of Cleveland, Ohio, has been installed as manager of the new factory sales branch of the White Automobile Company. The Archey-Atkins Company, of Indianapolis, has been appointed agent for the Hudson "33," succeeding the agency held by the Indiana Automobile Company, which has taken on the Reo.

Columbus, Ohio—Harry Joseph, who formerly operated a livery stable at the corner of Champion avenue and Oak street, has reconstructed the building into a modern garage. The second floor will be used for the storage of cars, while the garage proper and repair department will be on the first floor. The main entrance to the building is on Champion avenue.

Indianapolis, Ind.—Stockholders of the Mais Motor Truck Company held their annual election of directors a few days ago, the following new directors being selected: Dr. Albert E. Sterne, John T. Saulter, A. W. Markham, C. L. Chandler, W. H. Roberts and Albert Mais. H. W. Moore, formerly cashier of the Capital National Bank, has been appointed assistant treasurer of the Mais Company.

Milwaukee, Wis.—The Rambler garage at 455-457-459 Broadway, Milwaukee, Wis., will cease to be a public garage as soon as Alfred Reeke, sales manager of the Milwaukee branch of the Thomas B. Jeffery Company, is able to make the arrangement. The policy of the Kenosha Company is to make all of its branches Rambler service stations exclusively, with no side lines.

San Francisco, Cal.—A three-ton Kissel truck was used recently to transport grapes from Globe, Cal., to this city. The distance is 315 miles and the run was made in 31 hours. Fears were entertained that the 7,240 pounds of grapes could not be transported in the motor truck without bruising them, but they arrived in perfect condition, although the roads encountered were very rough and difficult.

Automobile Incorporations

AUTOMOBILES AND PARTS

Bay City, Mich.—National Motor Truck Co.; capital, $300,000; to manufacture and sell freight automobiles.

Birmingham, Ala.—Birmingham Automobile Company; capital, $10,000; to make motor vehicles. Incorporators: John B. Ransom, Geo. Bennie, B. J. Banks, Jr.

Canton, Ohio—Wise-Green Motor Car Co.; capital, $25,000; to make automobiles. Incorporator: R. P. Wise.

Cleveland, Ohio—Yale Cycle and Supply Co.; capital, $10,000; to manufacture, sell and repair motor vehicles and accessories. Incorporators: C. H. Ferguson, Laura A. Ferguson, Edward E. Tompkins, H. S. Jackson, H. E. Tiggie.

Detroit, Mich.—Morton Motor Car Company; capital increased from $5,000 to $10,000.

Donaldsonville, La.—Donaldsonville Auto Company, Ltd.; capital, $10,000; to make and deal in automobiles. Incorporators: K. A. Aucoin, Dr. S. Moore, Dr. V. Painchaud.

Joliet, Ill.—Joliet Auto Truck Co.; capital, $10,000; to manufacture and deal in automobiles and accessories. Incorporators: Phil F. Carroll, Milo M. Case, Wilbur O. Dayton.

Piqua, Ohio—Piqua Motor Co.; capital, $50,000; to manufacture automobiles. Incorporators: L. H. Wessel and others.

AUTOMOBILE GARAGES, ACCESSORIES, ETC.

Anderson, Ind.—J. H. Cloud Top Company; to manufacture parts; capital, $10,000. Incorporators: J. H. Cloud, W. A. Hester, P. B. O'Neil.

Buffalo, N. Y.—Eureka Seat Company; capital, $10,000; to manufacture automobile parts and seats. Incorporators: Joseph H. Morgan, Maurice J. Cogan, Norbert C. Kropp.

Boston, Mass.—Richmond Garage & Motor Company; capital, $15,000; to conduct a general garage business. Incorporators: Henry L. Richmond, Benj. V. Stevenson, Geo. W. Boland.

Cleveland, Ohio—Jepson Brothers Company; capital, $5,000; to deal in automobiles and motorcycles. Incorporators: James E. Sayne, Peter G. Jepson, Anna D. Jepson, Richard J. Jepson, Minnie A. Jepson.

Elkhart, Ind.—Brown Sales Co.; to deal in accessories; capital, $5,000. Incorporators: Walter Brown, Beryl Brown, E. A. Skinner.

Indianapolis, Ind.—Auto Lighting & Electric Company; capital, $3,000; to make vehicle lights. Incorporators: G. S. Monfort, C. R. Brown, F. C. Parker.

Jersey City, N. J.—Mechanical Rubber Tire Company; capital, $100,000; to manufacture tires and other rubber goods. Incorporators: Wm. T. Wheeler, Frank B. Crawford, Frederic Carter.

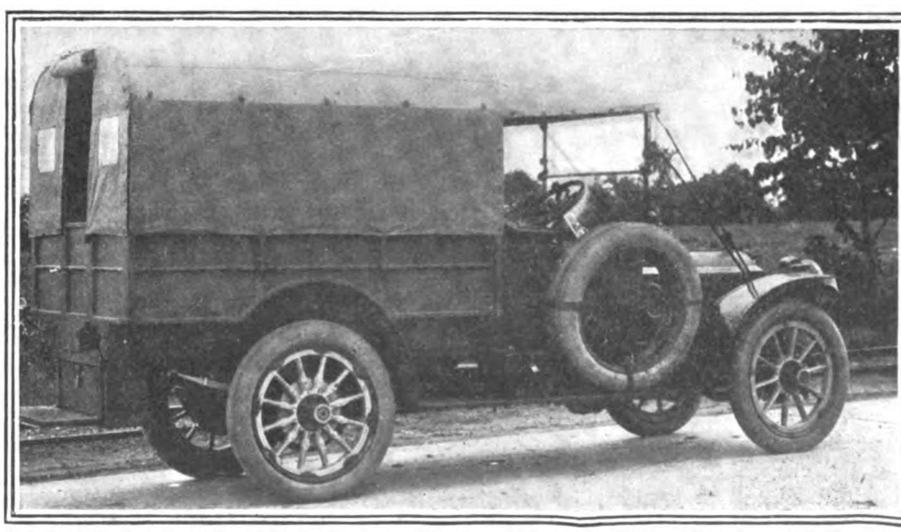
Kansas City, Mo.—Lawrence Automobile Brake Company; capital, $2,000. Incorporators: R. E. Bolen, Virgil Lantz, W. O. Sonum.

Montpelier, Ind.—Automobile & Supply Company, capital, $5,000; to deal in automobiles and supplies. Incorporators: E. E. Helm, J. F. Ireland, L. Ireland.

Philadelphia, Pa.—Detroit Electric Car Company, of Philadelphia; capital, $25,000; to buy and sell electric vehicles. Incorporators: A. M. Garrison, J. Morgan Russell, Amos S. Flowers.

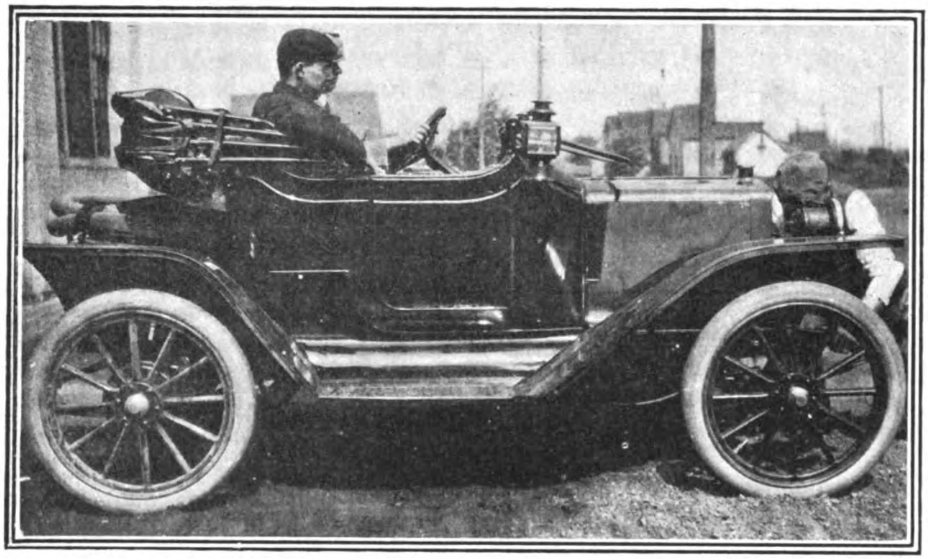
Springfield, Ill.—Packard Motor Car Co.; capital, $50,000; to manufacture and sell automobiles. Incorporators: Leslie L. Ayer, William Fogel, William L. Barnum, Jr.

Utica, N. Y.—Utica Auto Supply Company; to manufacture and deal in auto supplies; capital, $10,000. Incorporators: Howell D. Crim, Chas. S. Burrows, Oscar J. Brown.



The Packard special camping motor truck

OF INTEREST to the INDUSTRY



New R. C. H. car starting on long demonstration

DETROIT, MICH.—The R. C. H. runabout, a new creation of the Hupp Corporation, has started on its initial trip over the roads of Michigan. In the first three days the car covered 598 miles without developing any defects, making the run from Detroit to Grand Rapids, a distance of 162 miles, against the hilly and sandy roads between these points in good shape.

CHICOPEE FALLS, MASS.—O. C. Curtis, formerly of the Franklin Motor Car Co., will represent the Stevens-Duryea Co. in the South.

PORTLAND, ORE.—The Braly-DuBois Co., dealers in Franklin cars, will move to Nineteenth street, north of Washington street, on Sept. 15.

NEW YORK.—A new entry to the auto supply field, under the name of A. J. Picard & Co., will be located at 1720 Broadway after Sept. 22, 1911.

WASHINGTON, D. C.—W. C. Vliet, formerly assistant sales manager of the Buick Motor Co., has been appointed manager of the local branch of the E. M. F. Co.

AMESBURY, MASS.—The Graves & Congdon Co., manufacturers of the patent luxury automobile folding seat, have been reorganized under the name of the Hodge & Graves Co.

PORTLAND, ORE.—F. T. Bolton, formerly superintendent of the repair department of the Portland Automobile Company, has been promoted to the position of manager, taking the place of Ross B. Cooper, resigned. Mr. Bolton has been in the employ of the Winton Company for a number of years.

CHICAGO, ILL.—The Colby Motor Co. has opened a branch at 2009 Fullerton avenue. It will be under the management of W. H Ogren, formerly of the Logan Auto Garage Co.

PONTIAC, MICH.—The estimated output of the Oakland Motor Car Co. will be between 5,000 and 6,000 of the 1912 model. No shutdowns or layoffs are expected during the ensuing year.

BRISTOL, CONN.—Samuel B. Dusenberre, formerly with U. S. Motors Co., is now Western sales manager for the New Departure Manufacturing Co., makers of ball bearings. He will be located in the Ford Bldg.

ADRIAN, MICH.—Leslie B. Sanders, until recently sales manager of District B, United States Motor Co., has accepted a position in the same capacity for the Lion Motor Co. and has just entered upon his duties.

DETROIT, MICH.—P. W. Hood, formerly Western representative of the American Distributing Co., will shortly take up his duties as a sales representative of the Timken concerns. He will probably operate in Chicago territory.

DETROIT, MICH.—A camping car of the prairie schooner type has been built by the Packard Motor Co., for the use of Henry B. Joy, the president of the concern. The car has been designed and built to suit sportsmen who wish to make an extended hunting trip in deserted country and to remain independent of hotels. There is plenty of room for provisions and dogs, besides the regular camping equipment. The body is mounted on a standard Packard 30 chassis.

SYRACUSE, N. Y.—L. A. McKay, Western sales manager for the Franklin Automobile Co., is on a business trip through Wisconsin, Minnesota, North Dakota, Montana, Idaho, Utah, Wyoming, Colorado, Nebraska, Alberta and Manitoba.

ST. LOUIS, MO.—A. M. Pearson, of Philadelphia, has been appointed manager of the St. Louis branch of the Franklin Automobile Co. Previous to his appointment with the Franklin company he had charge of the truck department of the White Company in Boston and the Packard in Philadelphia.

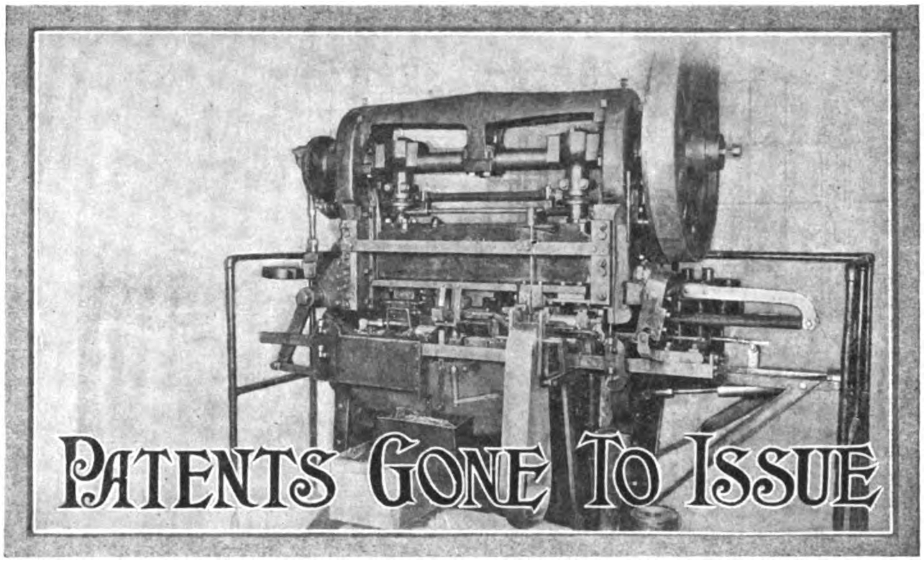
CHICAGO, ILL.—Lafayette Markle, formerly in charge of the Buick interests here, has been appointed general branch manager and supervisor of the E. M. F. Co.'s agencies throughout the United States. He will make his headquarters in Detroit. H. S. Johnston and C. B. Weaver, also of the Buick Co., will travel for the E. M. F. Co.

DE KALB, ILL.—Clinton F. Cook, formerly associated with C. B. Broughton in the general garage business, has purchased the interests of C. B. Broughton and will continue the business under the name of the West End Garage. C. B. Broughton will maintain a show and salesroom in the garage and will handle Buick cars in the greater part of De Kalb County.

DETROIT, MICH.—A branch of the Sheldon Axle Co. has been opened at 1215 Woodward avenue, the Sheldon company having felt a necessity of a branch in this city to take care of the rapidly increasing commercial vehicle business. C. H. Gleason, David Landau, consulting spring engineer, and W. M. Hogle, formerly with the Alden-Sampson Co., will handle the business.

SYRACUSE, N. Y.—The factory force of the H. H. Franklin Manufacturing Co. is being increased as rapidly as skilled mechanics can be obtained, so that during the coming month an increase of several hundred men will be made. The object is to prepare for an increased commercial and taxicab output. A two-ton truck will be added to the line when the essential details in construction have been decided.

CHICAGO, ILL.—The business of the Chicago Motor Car Co., Packard agents, has been taken over by the newly organized Packard Motor Car Co. of Chicago. It is located at Twenty-fourth and Michigan avenues, with H. M. Allison, former secretary of the Chicago Motor Co., in charge. The reorganization was made necessary by the accidental death of William L. De La Fontaine, vice-president of the Chicago Motor Car Co.



CONTROL MECHANISM.—A speed-change lever construction.

2. This patent (Fig. 1) relates to the combination of a shaft which may be turned or made to reciprocate by means of a lever, on the outside of which is provided a brake lever having a sleeve oscillating on the shaft mentioned to operate the brake mechanism. The sleeve which surrounds the shaft is provided with an actuating arm and extends beyond the last-mentioned lever. A guide for the levers is adapted to fulcrum the control lever in reciprocating the shaft, and another guide to confine it to any one of several paths of movement in turning the shaft, allowing the lever to oscillate in reciprocating the shaft.

No. 1,002,188—to Horace T. Thomas, assignor to Reo Motor Car Co., Lansing, Mich. Granted August 29, 1911; filed November 8, 1909.

RESILIENT WHEEL.—A mechanical wheel in which elasticity is insured by the use of tubular springs.

1. The wheel (Fig. 2) comprises a hub and felloe having apertures, the outer tire-carrying rim being provided on its inner side with a series of cups having central studs or posts. Tubular springs are seated at their outer ends in the cups with the studs entering their bores, while the inner ends of the springs are fitted with centrally apertured cups. Through these and the apertures of the wheel felloe radial bolts extend into the bores of the springs, the bolts being secured by nuts at inner and outer faces of the felloe as well as against the outer face of the apertured cup. The end of the bolts and rim studs or posts are spaced apart and disconnected to allow the springs to yield laterally as well as longitudinally.

No. 1,001,714—to Enos A. Wall, Salt Lake City, Utah. Granted August 29, 1911; filed February 25, 1911.

REGULATING VALVE.—A device to regulate the flow of liquids.

4. This valve has a high and a low pressure chamber with a partition between them and having an opening therethrough. The opening is lined with a different material shaped to form an upper and a lower valve seat between the two chambers. Within the liner a pair of valve members are operatively mounted so as to engage the seats, a second liner of larger diameter being located within the chamber above the opening and a piston mounted in this liner serves to operate the valve members.

No. 1,001,620—to George W. Collin, assignor to the Collin Valve Co., Bridgeport, Conn. Granted August 29, 1911; filed November 18, 1908.

WELDING OR CUTTING TORCH.—A burner producing a long, hot flame, using two gases under various pressures for the purpose.

2. The torch includes a chambered head having passages delivering to the chamber thereof from sources of gas supply, a tip with an injector nozzle of reduced area communicating with one of the said passages. The injector nozzle delivers into a mixing channel communicating by means of a duct with the other passages and delivering to the mixing channel at a point closely adjacent the point of delivery of the injector nozzle, the tip having another duct also delivering from the last-mentioned passage to the mixing channel at a point removed from the point of delivery of the injector nozzle, which is illustrated in Fig. 4.

No. 1,001,136—to John B. Burdett, assignor to the National Pneumatic Co., Chicago, Ill. Granted August 29, 1911: filed December 24, 1910.

LIFTING-JACK—Worm-gear type of automobile-lifting device.

4. The jack consists of a standard or column containing a lifting rack which engages with a pinion solidly mounted. A worm wheel is rigidly mounted, meshing with the pinion and having a common axis therewith and being driven by means of a worm. A frame which carries pinion, worm wheel and worm is pivoted to the column and adapted to move in one direction in order to bring pinion and rack out of engagement.

No. 1,000,140—to Herbert Austin, Bromsgrove, England; granted August 8, 1911; filed December 5, 1910.

Newest Ideas Among the Accessories

Cause of Blowouts

THE B. F. Goodrich Co., of Akron, Ohio, has supplied to us the following information in regard to the nature of the most frequent tire trouble, viz., blowouts:

Occasionally a tire will blow out from no apparent cause whatever. The tread seems to be in the best of condition, hardly worn, and yet, without warning, sometimes while standing in a garage, a bad blowout will occur.

The true condition, as shown in the cut, is that the tire has had a hard blow from a large smooth stone while running at high speed. Such a blow may cause the fabric to break seriously on the inside without leaving any mark on the outside. After that, it is only a question of time until the blowout occurs. Sometimes the break will allow a few plies of the fabric to pinch the inner tube, and the tire will deflate gradually.

It is because tire users do not understand such mysterious accidents as this that tires are so often misused, and the resulting breakdown blamed to faulty construction. The series of folders which is now being distributed by the B. F. Goodrich Company will help tire users to increase their mileage by having a better knowledge of the conditions which their tires are having to meet.

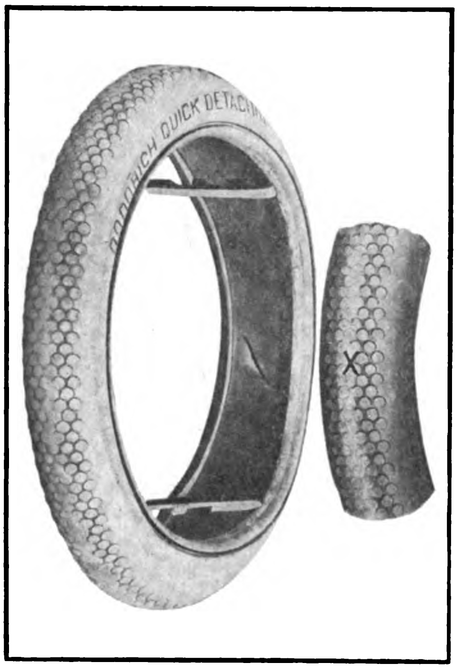

Fig. 1—Showing the tread of a Goodyear tire, as well as portion of it doomed to puncture

Brown Power Pump

Pure air is pumped into tires inflated by means of the Brown Impulse tire pump (Fig. 2), which is driven by the compression in one cylinder of the motor, a spark plug being removed to allow screwing the end of the pump into the valve cap. The pump is furnished with such interchangeable nipples of A. L. A. M. standard which permit of attaching it to any gasoline motor. The piston in the pump carries lapped iron piston rings. The whole apparatus is of small dimension and weight. It takes from one to four minutes to inflate a tire by the use of this pump, which is the product of the Brown Company, whose factory is located at Syracuse, N. Y.

Tuto Electric Horn

The Tuto, Fig. 3, is an electric signal with the sound produced by a diaphragm, which is vibrated by an electromagnet. The device is composed of a double coil and armature, a metal rod attached to the latter and a diaphragm located in front of and vibrated through the action of the double coil. The energy needed to produce the signaling sound is furnished by a set of dry cells, which are brought into play by pressing upon a push button. A slight pressure thereon closes the circuit, the current passing through a resistance. The double coil serves to make and break the circuit, thereby vibrating the diaphragm, which by this motion is made to strike the metallic rod extending toward it from the armature. This produces the sound, which is of a low but clear sort. The horn may also produce a high piercing note. The Dean Electric Co., of Elmira, Ohio, makes this signal.

Manco Safety Lock

The Manco safety lock is an accessory of manifold use for locking up change-speed lever, magneto and throttle controls, etc. It consists of two jaws (Fig. 4), hinged together. The jaws are capable of moving freely when the cam in the head is not in frictional engagement with its mating member, but when they are brought into engagement and the lock in the head is given a turn by the key, they are locked. The teeth of the two jaws are rounded. The lock will serve well in locking speed-change and emergency-brake levers together, in securing the throttle and ignition levers to the steering wheel or attaching the handle of a suit case to the railing of the car. Since the locking of the device is done on a friction basis of two members, it is possible to use the lock in fastening a coat or like article to a brass railing, thereby closing the lock as tightly as possible on the goods to be secured and then locking the accessory through the office of the key. The form of the teeth prevents their injuring the fabric of the material thus fastened to the car. The M. A. N. Manufacturing Company, of Providence, R. I., is the maker of this lock.

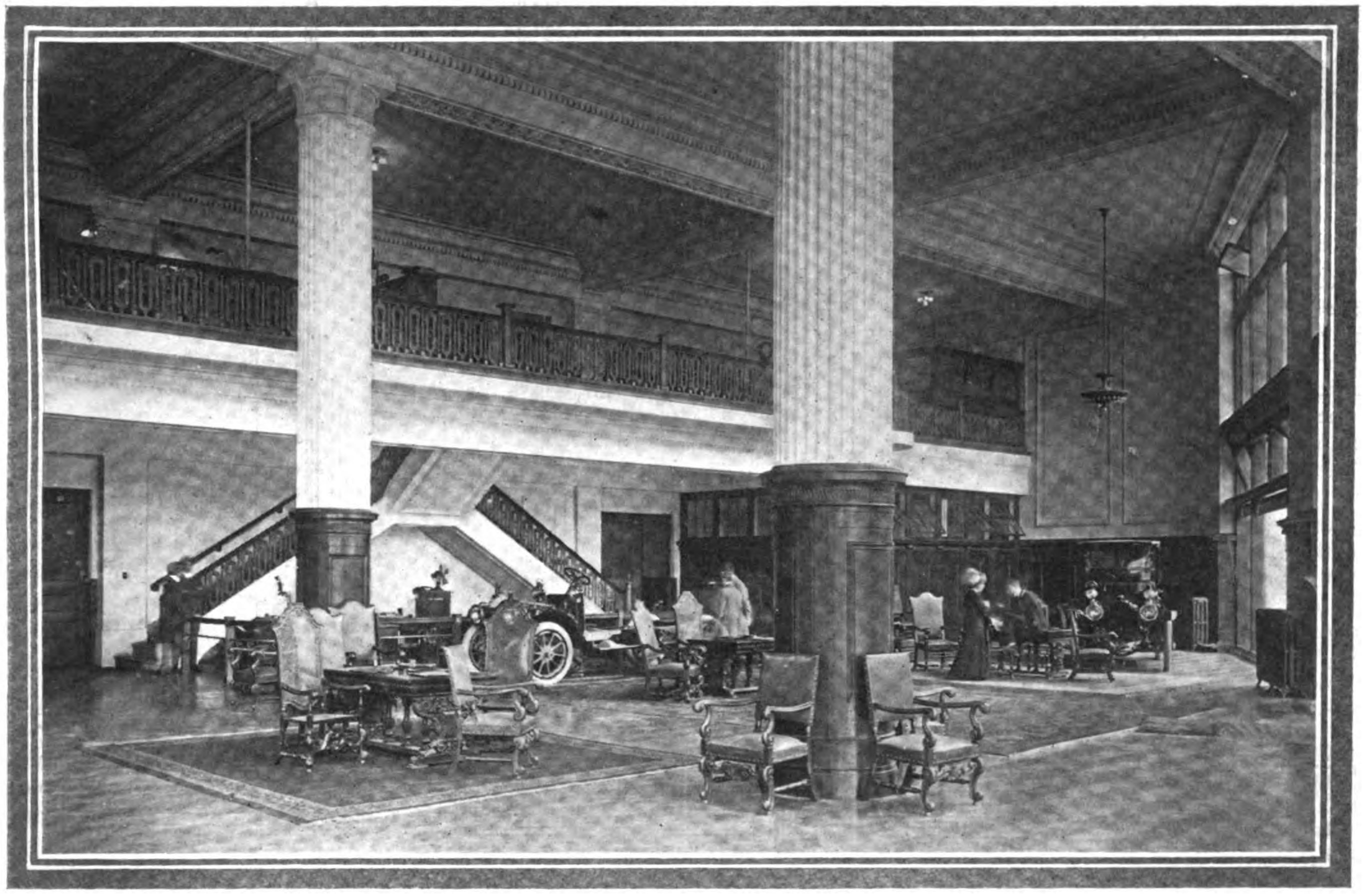
VOL. XXV NEW YORK—THURSDAY, SEPTEMBER 21, 1911—CHICAGO NO. 12

THE AUTOMOBILE

Psychology of the Showroom

How Beauty and Harmony of Surroundings Help Sell Cars



1—HOW A MODEL SHOWROOM LENDS ITSELF BY LIGHT, ORDER AND BEAUTY TO THE AUTOMOBILE

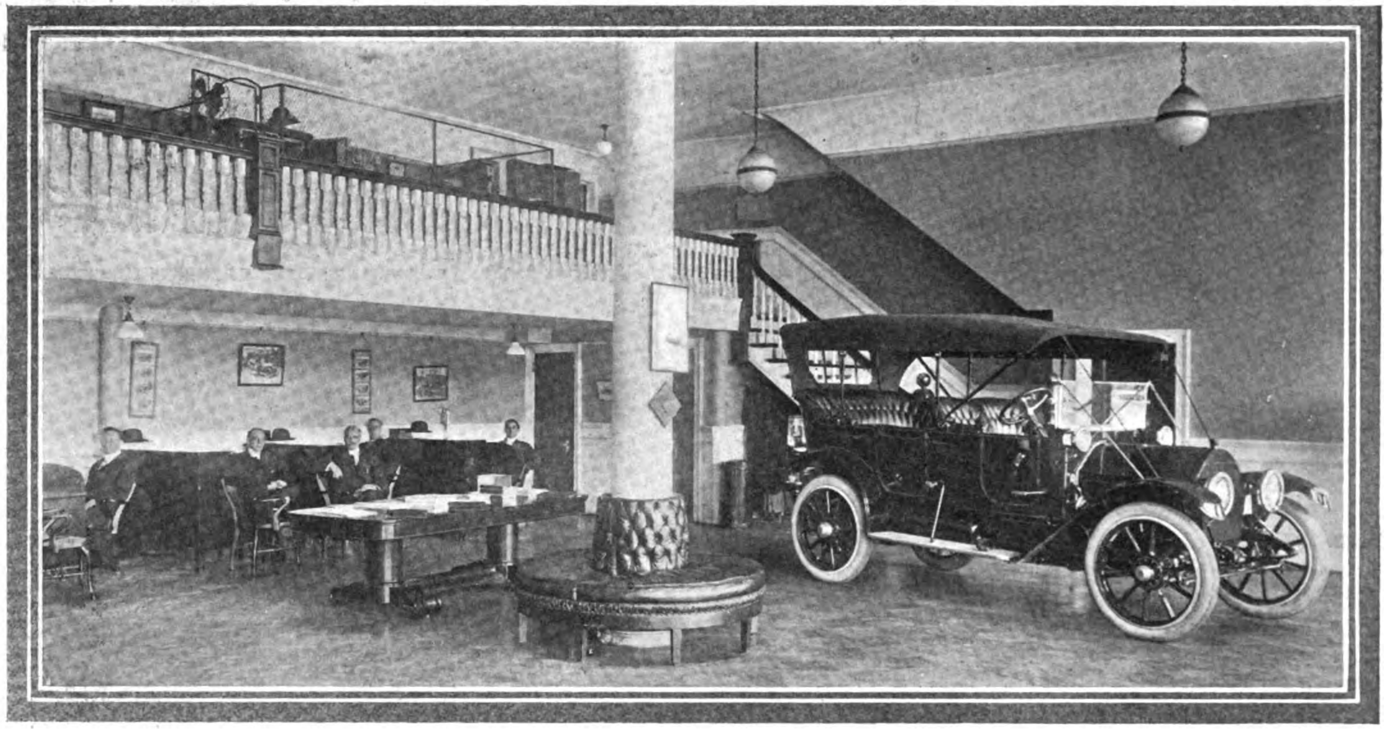
MANY more sales will fall to the lot of the automobile salesman whose wares are displayed in a light, roomy, well-ventilated, artistic, clean and comfortable showroom than can be made by the same man under opposite conditions. Of two men equally equipped and selling cars of the same class, the one that enjoys the better salesroom surroundings will sell more cars.

Psychology plays a most important part in the selling of automobiles. There are scores of different methods in use by salesmen and selling organizations, all of which are based upon the study of the human mind and its operations, with abstract and incidental application. Psychology reduced to its simplest term is the science of human nature and every salesman is obliged to take it into consideration if he is destined to make any marked success in his side of merchandising.

It has been truly said that there are no two human beings exactly alike and consequently no absolute rule can be laid down to govern salesmen in their relation to customers. In fact the same individual is rarely the same on two successive days and as a result the methods that might be acceptable one day would not answer the purpose at all on the second. But there are some general principles that apply to automobile selling that may be designated as axiomatic or fundamental, and these apply with almost equal force to any other line of salesmanship.

Advertising, under whatever guise it may be presented, lays the foundation for sales. It is the bait that attracts the buyers or possible buyers, and with that phase of the situation this article has nothing to do.

Assuming that an advertising foundation already has been laid



2—Salesroom in the middle of "Gasoline Row," where artistic and util'tarian features spell a big distribution and typical patronage

and that customers have been attracted, the next step is to justify the advertising expense by interesting prospective buyers in the line handled by the company. The personality of individual salesmen is an important point to be considered, previous acquaintanceship with the prospective is another, general reputation of the line is of necessity in the front rank, but quite as necessary as either of these is the setting of the car itself.

The day when it was possible to sell any kind of a car in any kind of surroundings is past. The customers of automobile selling establishments are growing more and more discriminating and the "hoo-raw" element has been eliminated to a large extent by automatic selection.

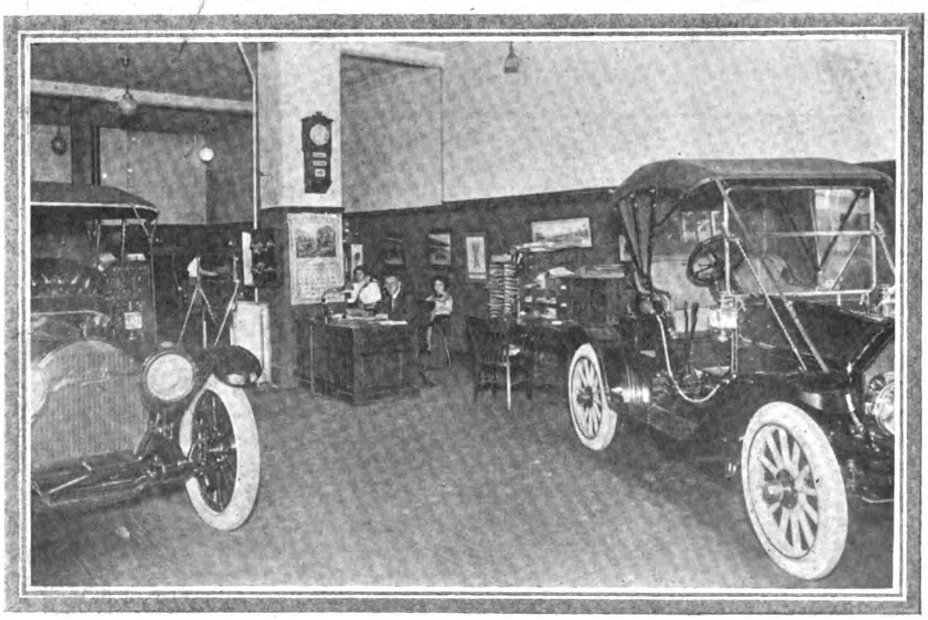
Of course, the business is still in a formative period, but it has progressed sufficiently to take it out of the "game" classification and place it among the great industries.

Therefore, as the business has grown to be keenly competitive the necessity for artistic and effective surroundings for cars offered for sale has grown to be more and more important until to-day it is regarded as essential.

If a line of well-advertised automobiles is displayed in cramped quarters it may succeed, but it is certain that it cannot obtain the degree of success that it would if it had been shown in the midst of effective surroundings. Just what that means is susceptible of many constructions.

The day of the automobile "store," which was so popular a few years ago, has passed and in present-day practice the store idea has been abandoned. The greatest care is now observed in the arrangement of the showroom so that the line may be displayed to the utmost advantage. There are automobile establishments in New York City that rival anything in their class in the world and there are others that make one wonder how the cars they sell ever managed to obtain any considerable vogue.

On the one hand, there are salesrooms such as several shown herewith that have been built with the single purpose in view of displaying the car, and there are others, as indicated in some of the acompanying pictures, that would appear to handicap sales by reason of crowded conditions and such a multiplicity of models as to distract the attention of prospective buyers.

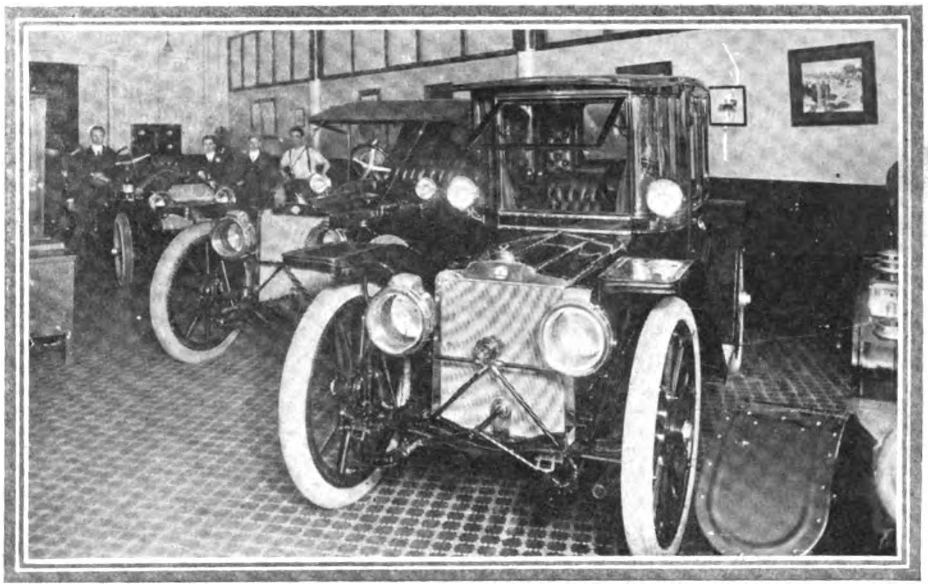


3—Cramped quarters and the dark and crowded store here shown will be exchanged shortly for a magnificent establishment in the same neighborhood

There are some gorgeous rooms, the interiors of which are like palaces, that seem so supremely attractive as to distract interest from the cars by centering it in the magnificence of the furnishings. Such rooms, of course, are not available for the sale of low or medium-priced cars and but rarely for housing even the highest grades of automobiles.

In New York City there are a number of highly ornate and ornamental rooms devoted to the automobile industry, but the most artistic and expensive of the lot was specially constructed to display its line of automobiles in the same way that the platinum setting of a blazing gem lends itself to additional lustrousness of the gem itself.

There are other types in which the element of luxury is subordinated and efficiency of display is emphasized. This type probably represents the highest development of the automobile showroom from the general viewpoint of results. There is no limit to price of the cars that may be economically sold amid such surroundings. For instance, one line of medium-priced automobiles recently has been moved into an unusually fine showroom in the heart of "Gasoline Row." The place is big and roomy, well furnished for the comfort of customers and is so arranged as to bring out the artistic lines of the cars in a way that was entirely impossible in the quarters formerly occupied by this concern.



4—Conditions as displayed here have proved so trying to this big concern that it will move to a spacious location where opposite conditions obtain

On the other hand, some of the most expensive of the automobiles manufactured in America are handled in large scientifically built structures that are similar in furnishings and equipment in many ways to the quarters of this cheaper car.

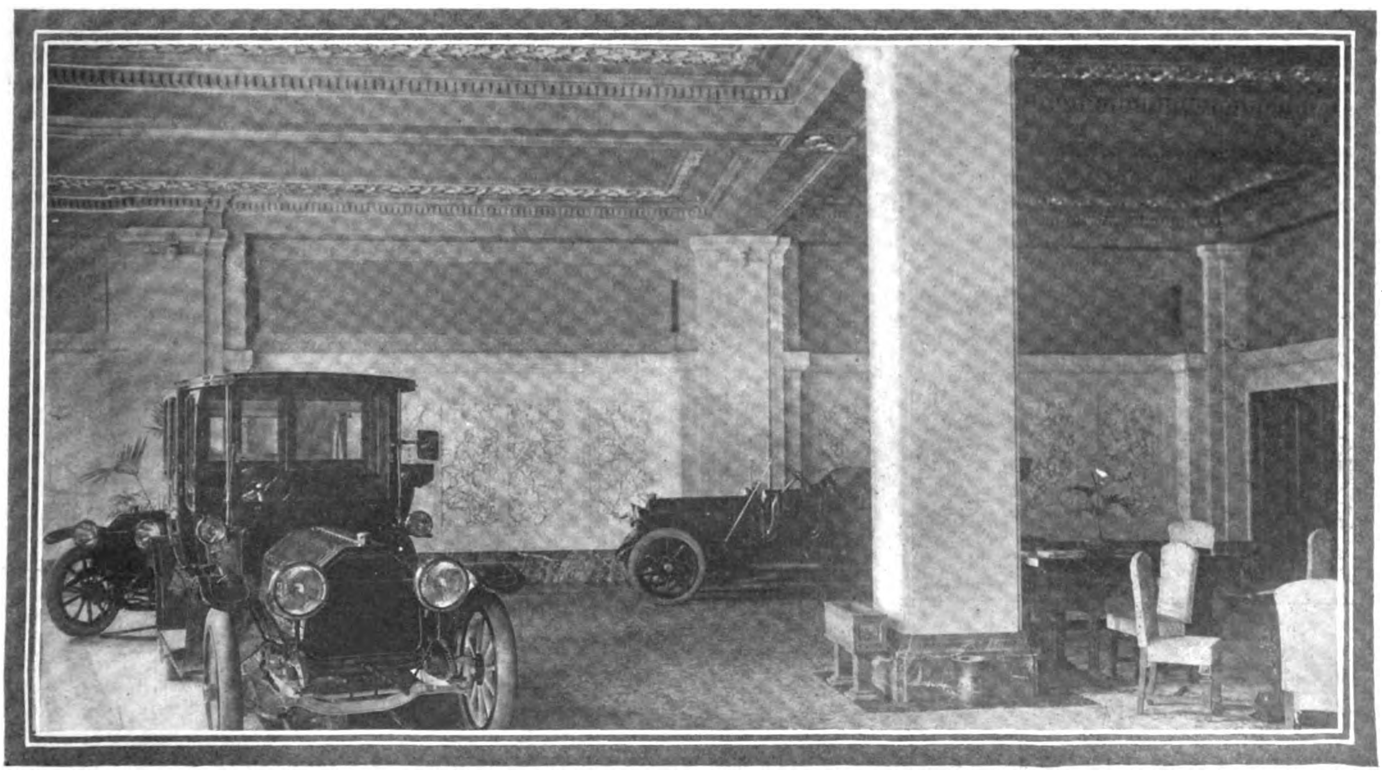
It would seem as if the forces engaged in selling automobiles were striving to reach some sort of a standard for salesrooms.

There are a number of successful companies that occupy cramped quarters at present. This is accountable to the fact that they are progressing in size and importance and they have really outgrown their establishments. Several of the illustrations herewith indicate crowded conditions and in each case the company involved has either made arrangements for more commodious rooms or intends to do so in the near future.

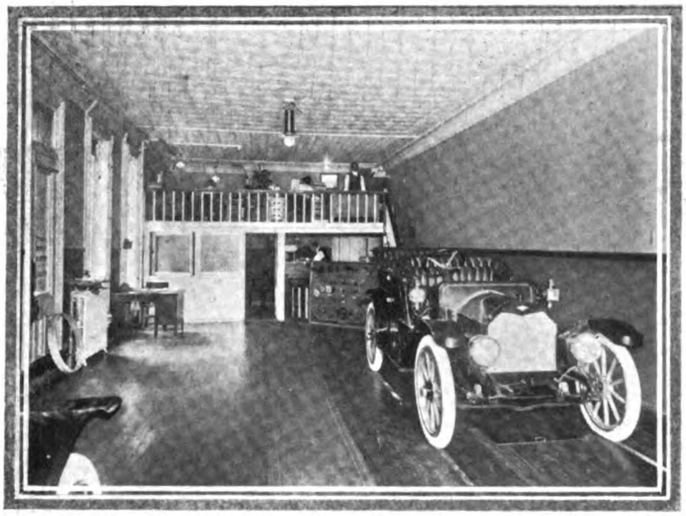
One big concern leased what was considered an amply adequate store for its requirements, making the arrangement several years ago when its business in the metropolitan district was small. At that time it was possible to show two models in such a way that access could be had to them from all sides and from various angles. The price was moderate and the car gave due service. The manager was fortunate in securing good salesmen and the combination proved successful. As business grew it became necessary to show another model and then another and as a result the showroom, ample for two cars, has proved much too small for four or more.

Consequently this company will remove in the near future to quarters nearly ten times as large as those occupied at present and it is safe to say that four cars will be the limit number of those displayed at the same time on the floor.

For quite another reason the quarters of the company shown in another figure seem to be crowded. This concern handles a double line of automobiles and is the eastern distributor for them in a territory that is very wide. Until recently it had quarters facing on a busy corner, but changes in the line of merchandise led to a change in location with the result that undue crowding



5—One of the most beautiful salesrooms in the world, where luxury and richness blend harmoniously to set off the merchandise



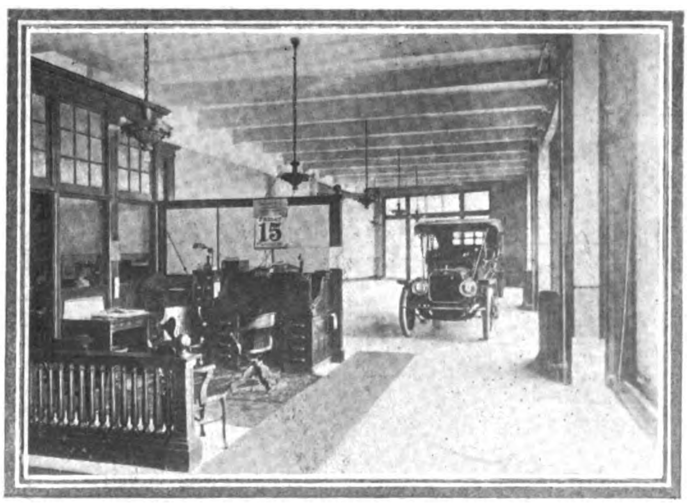
6—How a small room may be used advantageously to emphasize the attractive points of a single model

was experienced. This company will move shortly into a magnificent location further north on Broadway where it will have two floors of 10,000 square feet each, lighted with vast plate glass windows extending from floor to ceiling. In this place the same number of models that crowd the salesroom shown can be displayed in their individual beauty and attractiveness. As it is at present, it would endanger clothes to inspect all the models and by no chance could a proper perspective be reached. The new quarters will change all that.

In a number of the pictures it will be seen that a single car forms the focus of attention. Even where a concern handles a line consisting of a dozen or more models, it has been found advantageous to display only one, according to the aspect of some of these pictures. There is an element of psychology involved in this practice. The automobile salesroom in one sense is a store, inasmuch as the buyer is supposed to go there to purchase from its stock. But the selling of automobiles is somewhat different from selling groceries or cotton goods, because the customer rarely buys the identical car shown on the floor. Of course, he may do so in extraordinary instances, but as a general thing his purchase is made after observing a "sample" car.

Only in unusual cases is the company able to make delivery of a car to its purchaser on the same day the transaction is closed, for the reason that it takes time to get the car out of the warehouse or to have it shipped from the factory. Some of the companies do not promise delivery under thirty days.

For this reason a single attractive model, shown amid surroundings that harmonize with it and make for the comfort of the purchaser and the ease of his inspection, is considered better than the display of many models under any other conditions.

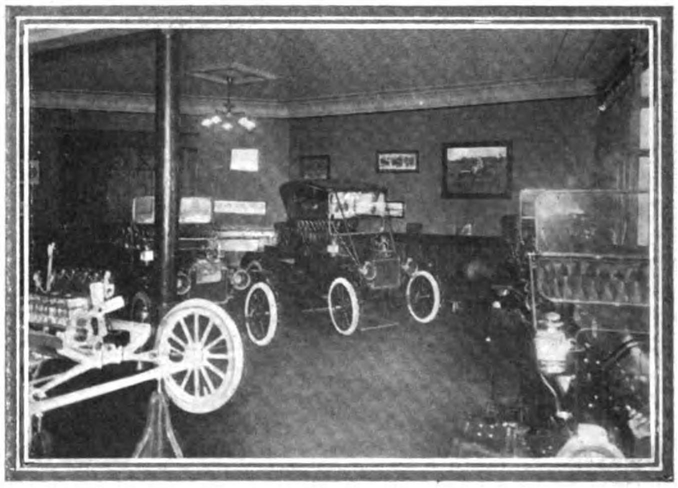


7—Vast expanse of plate glass and a businesslike showroom is sometimes used to exhibit one automobile with excellent results

One of the most successful sales managers on the "Row" explained how he handled his business, particularly with reference to the assistance lent or obstacles imposed by the arrangement of his salesroom.

"In the first place," said he, "the physical aspect of the showroom in the automobile business is quite as important for the sale of cars as the appearance of a jewelry store or a furrier's establishment in the sale of diamonds, silver fox and sables. No matter what car is handled, its surroundings should be in harmony with it. To my mind it would seem the height of folly to crowd a room full of cars so that inspection would be difficult even in moderate degree. The place must be clean and bright. There is nothing so thoroughly out of place in an automobile salesroom as disorder. The car is a bit of mechanism, representing the last word in the development of transportation and deserves, first of all, to be clean in its surroundings. Second, the matter of light should be considered. If the showroom has a polished floor and the windows extend close to the floor, there will be an added quality to the light that will go a long way toward making sales. Third, there should be an understanding and intelligent arrangement of the interior of the room.

"If the establishment is large enough to handle a number of models, there is room for the display of considerable ingenuity in their arrangement. Six cars backed against the wall with only just room enough to pass between them is not nearly as good as three models so placed that the customer has a chance to see them from all sides and to reach them from both ends.



8—This picture shows the exception that goes to prove the rule, and still if more space and light were used the sales might be even greater

"It is to be assumed that ventilation, heating and a reasonable degree of artistic merit in the decorations have been provided.

"In a showroom of only medium size which would be sufficient to house possibly eight cars, it is my idea to cut the number in half. I place one of the big cars, equipped with a striking top and attractive coloring, at an angle to the show window. This is to catch the eye of the casual visitor or passer-by to a certain extent, but in the main the object is to create a pleasant impression upon the prospective buyer who visits the establishment seeking an automobile.

"After passing the show window to the front door and seeing the big car nicely displayed, the visitor walks by this model and his interest is taken up with other things. Perhaps the car we have been pushing is one of smaller size and possibly we might have trouble in making prompt delivery of replicas of the big car, at any rate the buyer has a chance to see the first car and gain an impression of size and power from it. I have found it most effective to place the special object of our selling in the middle of the room where its lines will show to advantage and its points will be easily observable.

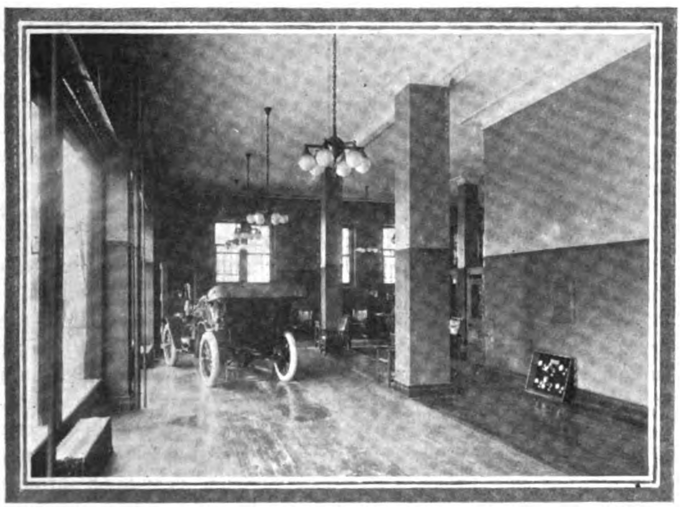
"I make it a point to have only a little furniture in the room so that nothing can detract from the cars themselves by distracting the attention of the customer. Naturally there must be a few chairs and settees and a little greenery is not amiss, but in my opinion these may be reduced to the minimum.

"The salesman should never meet the customer at the door, it gives a wrong impression of eagerness and has spoiled many a sale. Let him advance toward the caller a little less than half way, thus making the customer take the attitude of the inquirer. With the picture of the big car in his mind it is easier to direct the customer toward the leader of the line which may be of less cost, than it would have been if the positions of the models had been reversed.

"I have seen sales lost through over-eagerness on the part of salesmen, but I recollect no case of the kind that resulted from thoughtfulness in this particular.

"There is no element of misrepresentation in placing a big, expensive car in the most prominent place in the showroom as viewed from the street, even though your advertising campaign has all been directed toward the sale of some other model. Automobile buyers of to-day are not children and in the vast majority of instances I have found that they have a pretty general idea of what they want before they start out to make their purchases.

"After the interest of the customer has been aroused in the car it is time to explain the mechanical features as shown in a

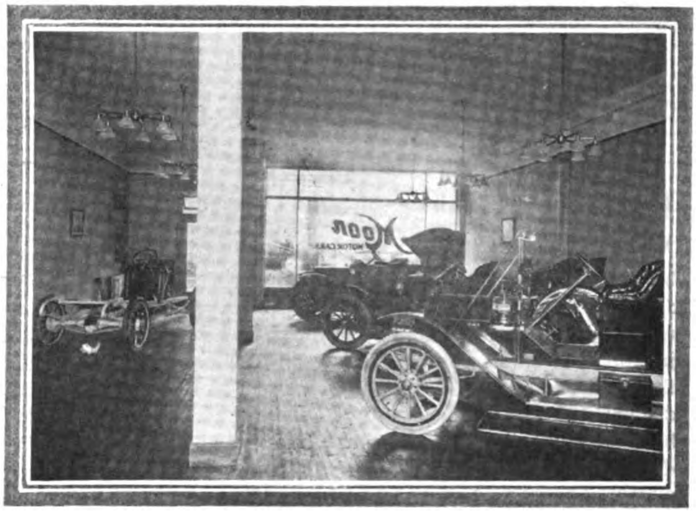


9—Ordinarily three models are shown in this room, which is a model in its way, but stocks are low at this time of the year

cut-out chassis. I find that it is not necessary to place the chassis in the most prominent place in the room. Let it be off to one side, because the customer will have to be led to it in any event. In many of the best salesrooms no chassis is provided for ocular demonstration, that part of the sale being accomplished at the garage.

"Another thing that I would call particular attention to is to criticise the rather common practice of displaying used cars in the same place with the current stock. Automobile buyers are a sensitive lot. The bulk of them are business and professional men of wealth and importance in the community and as such they do not wish to throw themselves open to the charge that they are contemplating the purchase of a second-hand car. On the other hand, there are many estimable persons who do wish to buy second-hand cars and they, too, might have some little delicacy about examining the stock of used machines in the same room with their neighbors who may be buying new cars. Thus, there is nothing to gain and everything to lose by showing both varieties in the same room."

The whole matter may be summed up in a few words. From 5 to 30 per cent. of all inquirers for automobiles purchase cars. The percentage is much higher in the fine roomy establishments than it is in those where the cars cannot be displayed to the best advantage. Reckoning the average of



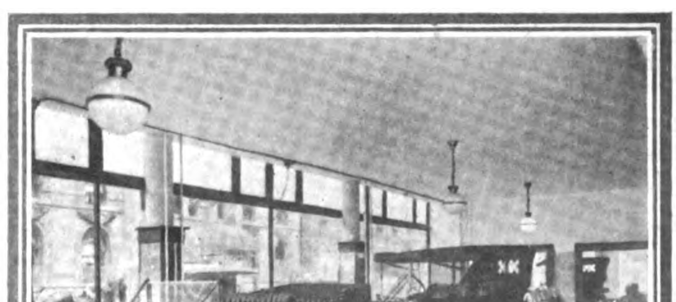
10—A little crowded, but effectively arranged. This room would look better with only two cars on the floor

actual buyers in the best of the shops at 15 per cent. of those who inquire and at the poorest establishments at 8 per cent., it will be seen that there is a vast amount of business that is accountable to good surroundings, or in the converse attitude, lost to some concerns because of opposite conditions.

Now that the automobile is on a strict dollar value basis, it behooves selling concerns to recognize the utility and necessity of conforming to the best practice as regards the setting of their merchandise. Only a few lost sales would represent the actual added money expenditure necessary to convert a "sow's ear into the proverbial silken purse," and on the other hand a few additional sales each season would balance the augmented expenditure.

Under sharply competitive conditions as they obtain now and as they will probably be accentuated in the future, additions to the business of a concern, even when achieved at the expense of a greater investment, must be reckoned as an important element in its life. Consequently the importance of scientific showrooms is of sufficient force to deserve even greater attention than has been given this feature so far in the development of the automobile industry.

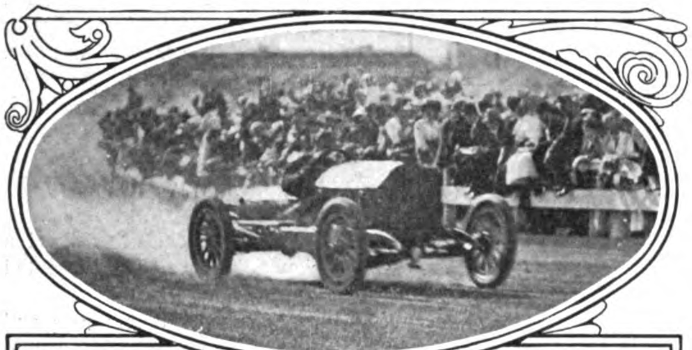
CONCERNING TIRE DURABILITY—The life of a tire, other things being equal, is proportional to the square of the section diameter. The square of 4 is 16 and the square of 3.5 is 12.25. The life of the 4-inch tire from this point of view will be as 16 is to 12.25 comparing it with a 3 1-2-inch tire.

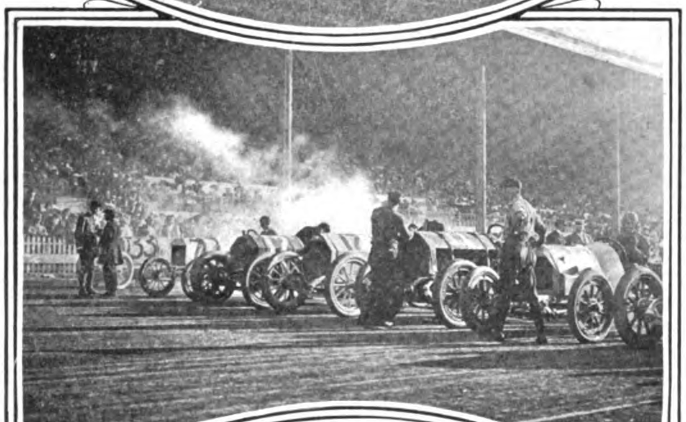


11—One of the most scientifically arranged show rooms in New York, the home of a concern that outgrew its old quarters on upper Broadway

Fatalities Mar Syracuse Meet

SYRACUSE, N. Y., Sept. 18—A day of splendid motor racing sport, upon what visiting cracks declared is the premier dirt mile track in America, was shadowed to-day by a tragedy in the special 50-mile event which cost eleven lives and the injury of half a score. In the forty-third mile of this race, watched breathlessly by a throng of 75,000 persons that jammed the giant stands and stretched many deep about the fences clear around the track, a front tire on the Knox machine, driven by Lee Oldfield, blew out upon the turn leading into the back stretch, the driver losing control and the car shooting diagonally across the track and into the outer fence, behind which were massed many spectators. The car plunged through the crowd, flinging mangled human forms high in air, and ploughing through a bed of soft cinders, turning over and over and stopping far beyond the scene of impact, a dismantled wreck. When the final toll was taken Saturday, it was found that eight men and one nine-year-old boy, who was found clinging to his dead father's hand, had been killed and eight others had been injured, some fatally. Two others died on Sunday.





Ralph De Palma in Simplex on last lap of 50-mile race, in which he established new records

Start of 50-mile race, run in two classes simultaneously, Simplex winning in Division B, and Abbott-Detroit in Division A

Close finish in the 301 to 450 race between Burman in an Opel and Turner driving an Amplex

Despite the seriousness of the accident the contest continued, and at its close Ralph De Palma in his Simplex finished without a stop on one flat rim and with the new world's figure of 47:21.65 for 50 miles done on a dirt circular track to his credit. When the first half of the race was done he had negotiated a new 25-mile world's mark of 23:15.15. His division in this merged race was Division B, for cars 300 to 600 cubic inches displacement. In Division A, the Abbott-Detroit, driven by Mortimer Roberts, which plugged through without stopping, was the winner.

After the death-dealing crash occurred the drivers looked toward the officials as the machines came around the home stretch. Apparently the pilots expected the signal to stop. But none was given, and they kept on. It was by a miracle, seemingly, that others were not killed during the remainder of the race, for the track at the scene of the accident was half filled with people. In taking that turn for the remainder of the race, De Palma and the others reduced speed appreciably and threaded their way with wonderful dexterity among the reckless groups that had encroached upon the track.

With the conclusion of this race two more events—the second heat of the Remy Grand Brassard and the 5-mile open class—remained to be run. Starter Wagner lined up the contestants for the second heat of the Brassard event, but there was a menacing growl of dissent from the crowds. After a hurried consultation in the officials' stand the remainder of the program was called off. It was a ghastly finale to the most exciting day of motor racing sport this city has ever seen.

Shortly before the start of the fatal race, President Taft, the guest of honor for the closing day of the New York State Fair and the honorary referee of the automobile events, had been driven in an automobile and with a military escort past the stands.

From the standpoint of racing, the day was a complete success. Earlier in the afternoon Burman broke the track record for a mile, flying start, with the Blitzen Benz, despite a broken piston. When his car began to wobble after the breakdown Burman worked like a Trojan at the wheel and managed to keep the car away from the fence. He lowered the track record of 48:92, made by De Palma in his Fiat here in 1910, by 1-10 second, and had it not been for his mishap, he would undoubtedly have bested the Brighton mark of 48:62, made on Labor Day.

In the event for the Remy Brassard and trophy there lined up De Palma in his "50" Simplex, Burman in a Jenatzy Mercédes and Kilpatrick in his 200-horsepower Hotchkiss. De Palma won the race in 2:54.57, though Burman finished close to him.

In Division 2, Class C, 161 to 230 inches displacement, the Ford, driven by Frank Kulick, and the Abbott-Detroit, Mortimer Roberts, had a stubborn battle that brought the great crowd to its feet. Roberts succeeded in nosing out his opponent by half a car's length, and as he won again in his class in the 50-mile event, with the same car, he was one of the stars of the day.

The most sensational finish of the day was furnished in the 5-mile event for cars with piston displacement from 301 to 450 cubic inches, when Burman, in the Opel, trailed Turner in the Amplex for the entire distance till the last turn into the home-stretch, then sent his car down the stretch like a bullet, just nipping the honors at the wire by a nose.

The event for cars of piston displacement from 231 to 300 cubic inches proved to be a struggle between two speedy Mercers, and Hughie Hughes, out for blood, succeeded in beating De Palma, doing the 5 miles in 4:57.22.

In the seventh event, for cars 600 inches in displacement and less, with a minimum weight of 2,100 pounds, De Palma scored his first victory of the afternoon. Besides his Simplex and Burman's Opel, the other starters were the Amplex, driven by Bill Turner; the Knox, Fred Belcher, and the Cino, John Raimey. Belcher stalled his engine at the pistol's crack and was out of it without moving. At the end of the first mile Burman dropped out because of tire trouble. The Cino car retired during the next mile for a similar reason. At the end of the fourth mile the Simplex had a quarter-mile lead over the Amplex, the only other car left in the race. De Palma completed the tenth mile a half-mile in the lead in 9:39.56.

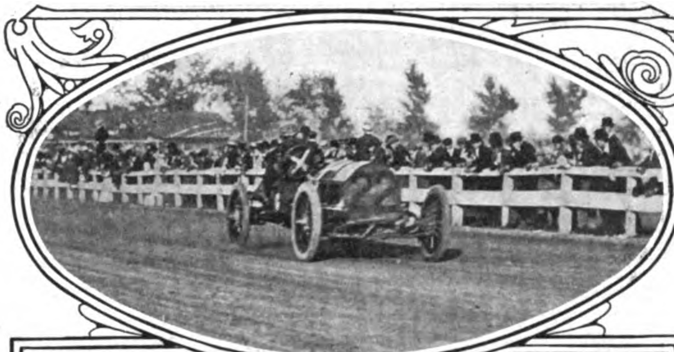
Just previous to the Remy Brassard event the Presidential party and escort passed around the track, preceded by a "water-wagon." Someone, in the desire to avoid the inhalation of dust into the Taft lungs, had given orders for a sprinkling cart to precede the parade. The entire homestretch was soaked and slippery and the starters for the Remy Brassard properly refused to endanger their own necks and those of the crowd till the track should dry. So there was an hour's delay, while everyone watched the aviator's flights and the balloon ascension.

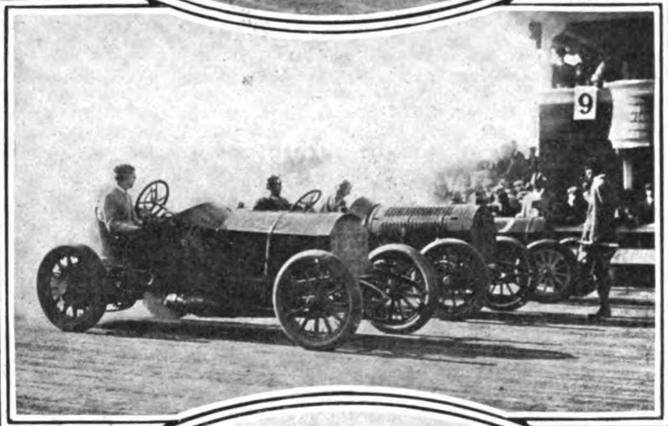
When the race was finally started three cars leaped away in a flying start for the three-mile flight. Burman drove the Mercedes car which Lee Oldfield had been scheduled to drive. De Palma was at the wheel of his Simplex and Kilpatrick guided a Hotchkiss. The race was all between De Palma and Burman, though the Italian was never headed. The Mercedes came up to close quarters several times, but the Simplex leaped away, and in the final rush it captured first honors by 200 feet in 2:24.57.

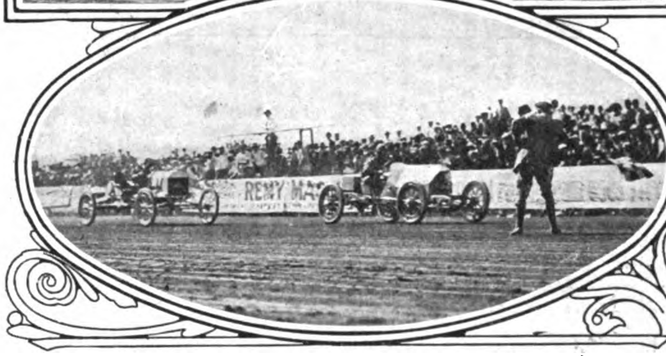
There was another delay before the 50-mile race was under way. A big field from the combined divisions faced the starter, including Burman's Opel, De Palma's Simplex, Oldfield's Knox and Turner's Amplex in Division B, while in Division A there were Hughes, Roberts, Morton and Raimey driving, respectively, a Mercer, Abbott-Detroit, Kline Kar and Cino. At the start of this ill-starred event the Simplex, next the rail, leaped away in the lead, and when the tangle had unsnarled the Opel was found in second place, close to its rival's wheel. Third was the little Kline Kar. The crowd in the stand cheered frantically as the cars came around the first time, and at the end of the second mile, the order was unchanged. With the third mile, however, Burman had dropped back to third place, and soon afterward had to quit because of engine trouble.

De Palma's car continued to sweep around in splendid style, continually increasing its lead. The Knox grabbed second place for several miles, when Turner's Amplex headed it. And, by the way, in the programme Fred Belcher was scheduled to drive the Knox, and Oldfield was substituted without any announcement to that effect being made from the official's stand. This Knox car was sent here for the races from Springfield, Mass., the home of the Knox Automobile Company. It is the car which Belcher drove in the 500-mile Indianapolis race. Belcher drove it here from Springfield and it was then turned over to Lee Oldfield.

While the higher-powered cars were struggling, the sturdy little Abbott-Detroit kept plugging on. Other cars in its class ahead of it had to stop frequently to replace tires and the final result was that, without having to halt for any accident, it won.







Mercer No. 22, driven by Hughie Hughes, which captured first place in the race for cars of 231 to 300 cubic inches

Line-up for the start of the Remy Brassard, won by Simplex, De Palma, from the Benz and Mercedes

Abbott-Detroit, driven by Mortimer Roberts, winning the race for cars of 161 to 230 cubic inches

The race had drawn well toward its finish, and De Palma had long since annexed a new world's record for 25 miles, when the Knox and Amplex, which had been in close rivalry, tacked into the car of the flying De Palma, Oldfield in the lead. De Palma was then just a lap ahead of them. For circuit after circuit the race continued. Suddenly, in coming down the homestretch, a yell broke from the crowd. There was a loud report and the tread of one of De Palma's tires flew high in the air. He kept on and the rubber was immediately ripped in pieces by the crowd for souvenirs. On the second lap thereafter the accident occurred.

SUMMARY OF THE EVENTS HELD IN CONNECTION WITH THE STATE FAIR AT SYRACUSE, N. Y.

Pos.	Car.	Driver.	Time.
	161 to 220 Cubic Inches, Five Miles

The Saurer representative in the big division, 10,001 to 15,000 pounds

32 Vehicles Start in

CHICAGO, Sept. 18—The first commercial motor vehicle test run under the system evolved by the rules committee of the Manufacturers' Contest Association, which makes the affair a demonstration instead of a contest, is now on, with the Chicago Motor Club acting as master of ceremonies. Complying with the wishes of the truck makers, the event is designed to show the business world just how the power vehicles operate in business service. The three routes chosen are mostly in the city or include adjoining towns which really seem to be parts of Chicago; the trucks carry their catalogued loads in the shape of sand; they are allowed ample time in which to make the trips and the penalizations are imposed only for replacements, taking on supplies outside of controls, for lateness and for damaged or lost parts as shown in the examination at the end of the test.

The routes selected for the affair aim to take in the entire commercial and manufacturing districts of Chicago and adjacent suburban cities. To-day the trucks went to Hammond by way of Whiting; to-morrow they run north to Evanston in the morning, stop at noon at the stock yards to allow the packers to inspect the cars and in the afternoon go to Oak Park and return; Wednesday the journey is a trifle more strenuous, being to Chicago Heights and return. The running schedules vary from 5 to 11 miles an hour, according to class.

As a means of comparison, the club has arranged to send out a two-horse truck carrying two tons of sand to-morrow, with Chicago Heights as its turning point. It is calculated that it will take at least two days for the horses to make the round trip, which will make them finish at the same time as the motor trucks, which, however, do not go to Chicago Heights until Wednesday.

In the entry line the club has made a record. In the first place it secured thirty-two nominations representing twenty-three concerns, which is a bigger entry list than the Chicago-Detroit run had and at five times the entry fee; in the second place every truck nominated started this morning from the White garage at Wabash avenue and Twenty-sixth street.

The first day's run eliminated only three of the perfect scores, one of them being a withdrawal, another a minor penalty for taking on oil and the third a big demerit which probably will put the car out of the running for a prize. The Swanson was the

Chicago Truck Run

one to pull out, its withdrawal being caused by a skid which broke a radius rod on the run home this afternoon. The Monitor first had clutch trouble, then rear axle trouble, which brought 338 points penalty, to which was added 300 more for being late at the night control. The veteran Reliance, known as old Adam and which is declared to be the oldest truck in Chicago from a service standpoint, having been running for a local brewery for 5 years, had to take on oil, for which it was assessed 3 points. The oiler on old Adam is a small one, fitted years ago when no one expected the trucks to do their 60 and 70 miles a day.

The run to Hammond and back to-day was more of a strenuous test than had been anticipated when the route was laid out. Ordinarily the trip would have been an easy one but Sunday night Chicago was deluged by a downpour of rain that "raised Cain" with the country roads. Of course the trucks could not run on the boulevards and to add to the trouble it was forbidden to strew confetti inside the city limits, which made the drivers go carefully in order to avoid losing the course. On top of this the contestants on their way back found a big gang of workmen tearing up the street car tracks at South Chicago avenue and Stony Island avenue, where the road is not too good anyway. This caused a congestion that looked serious for a time, but eventually the tangle was straightened out and everyone got through.

The noon stop at Hammond found every truck there on time. The 1-ton Decatur, pneumatic shod and carrying a ton of sand, made a remarkably quick run of it, covering the 20 miles in 1 hour and 18 minutes. It was demonstrated, however, that a pace of 11 miles an hour is a trifle too fast for the lighter vehicles over such roads while the big fellows are not asked to go fast enough on a 5-mile an hour rating.

It is interesting to note that the thirty-two vehicles carried in all 61 tons of sand which shows that the average load capacity of this representative field runs close to 2 tons per car—a very high average indeed.

Six Penalized the First Day

CHICAGO, ILL., Sept. 19—The second day of the commercial motor vehicle demonstration saw five penalizations and of this number two withdrew—No. 32 Alco and No. 21 McIntyre. The former burned out a bearing, while the latter hit a beer wagon,

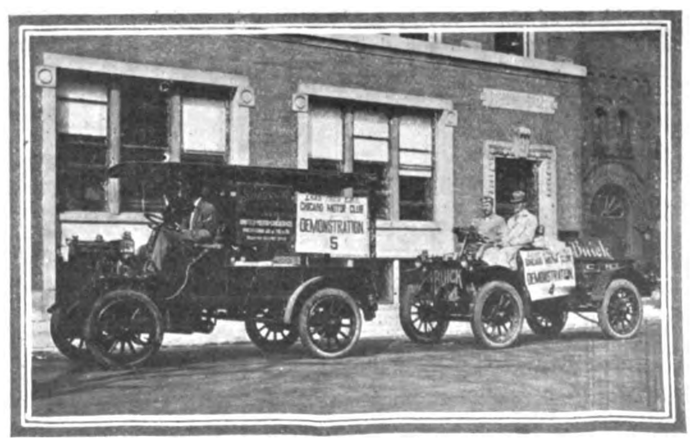
McIntyre, No. 21, only starter in 2,001 to 3,000-pound class

Clark No. 10, Wallwork, driver, one of a pair in 1,501 to 2,000-pound class

Stegeman, No. 30, which started in the 7,001 to 10,000-pound class



Sampson and Buick, two starters in 1,001 to 1,500-pound division

Pope-Hartford, No. 28, which will strive for the honors in Division 8K

demolishing the steering gear. Besides this, No. 2 Mercury, was penalized 72 points for coil trouble; No. 14 Adams, 6 points for taking on oil outside of control, and No. 23, Reliance, which was penalized yesterday 316 points for replacing a bearing. No. 19 Monitor, heavily penalized yesterday, did not start to-day.

The run to-day was to Evanston in the morning, returning for the noon stop at the stockyards, where the trucks were held an hour and a half in order that they might be inspected by the packers, while in the afternoon they went to Oak Park and back, making a day's journey of 61 miles. The stockyards stop was a happy idea, for great interest in the trucks was shown by the packers, and it is expected that considerable business will result.

The horse-drawn truck, loaded with two tons of sand, made its getaway this morning and to-night is at Homewood, 20 miles out.

No one wanted No. 13, so it was given to the horse rig, which is expected to finish to-morrow afternoon, using two days for a journey the truck will make in one.

With two-thirds of the run over there are two-thirds of the contestants left with perfect scores. It looks as if there will be at least 20 clean to-morrow night. Thursday morning there will be a mild sort of a final examination, in which only the steering gears, brakes and transmissions of the contesting vehicles will be examined.

Good Roads Congress in Chicago

CHICAGO, Sept. 21—The fourth annual international good roads congress and exposition opened in Chicago yesterday for a lengthy run, with representative men from all sections of the country in attendance. The congress is being held at the La Salle Hotel, and will continue to October 1. Governors of many States have promised to attend and it is hoped to have one of them preside each day of the congress. Arthur C. Jackson is president of the congress, and among the weighty propositions he has mapped out for discussion are the Jackson memorial highway, a national turnpike from Los Angeles to New York, and the proposed Lincoln memorial highway. The congress also is expected to strongly advocate the employment of convict labor on the roads.

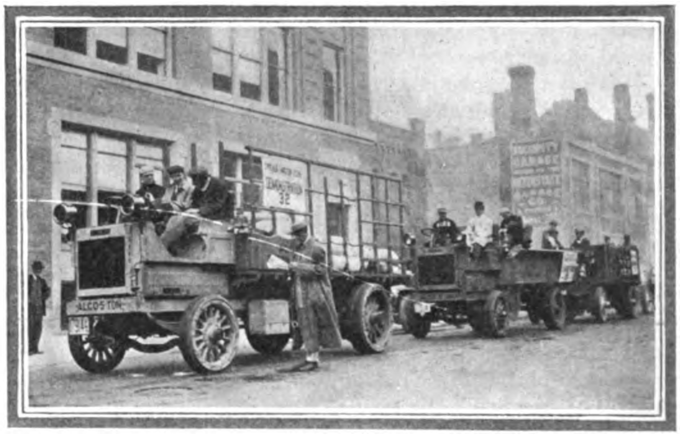
Chapin Named as Good Roads Delegate

DETROIT, Sept. 18—Roy D. Chapin, of the Hudson Motor Car Company, is one of the five Detroit men named by Governor Osborn to represent Michigan at the Fourth International Good Roads Congress, to be held in Chicago September 18 to October 1. The others are: Edwin S. George, Horatio E. Earle, father of the good roads movement in Michigan; Ben Otto and H. S. Nimmo.

Chalmers Owners Tie

DENVER, Sept. 18—The second annual Chalmers Owners' Consistency Tour, run on Thursday and Friday last, from Denver to Estes Park and return, resulted in a tie between Allen DeBerry Bowen, driving car No. 3, and Dr. Edward Lazelle, driving car No. 18. The result was in doubt throughout the entire race. Twenty-four cars entered the event, and, although all were driven by amateurs, there was not a single instance of mechanical trouble in the entire distance of 200 miles, and the tire troubles were confined to the one car driven by E. B. Field, Jr. Within the coming week the two leading cars will decide the tie by a run to Colorado Springs and return, and it is expected that a number of other auto enthusiasts will act as escorts.

Messrs. Bowen and Lazelle had only two points charged against them, and the third car, driven by F. C. Dreher, was charged with only three points. The showing is remarkable inasmuch as the drivers were comparatively unskilled in tour driving and that there were nine secret controls along the road, a penalty of two points being made against any car passing the control either two minutes behind or ahead of schedule.



Alco pair, both of which finished with a perfect score on first day

The twenty-four competing cars left the starting point at 8:30 Thursday morning. They were started off one minute apart, the schedule being so arranged that the average speed of the first car was 17 miles an hour, the second 18 miles, the third 19 miles, the fourth 17 miles, and so on.

Fairmount Park Race Comes Next

Eight entries have been received so far for the Fairmount Park road race, the classic automobile event staged each Fall at the Quaker City. The event is scheduled for October 7 and in the past has always developed a picturesque contest. The entry list is limited to thirty cars and the experience of the past has been that the bulk of them come in late. Usually the list grows to about ten until a week from the date of the race when the box is swamped.

The race is to be held under the auspices of the Quaker City Motor Club and will be run in Class C, Divisions 3C, 4C, 5C and 6C. The entry fee is $500 and the winner in each division will get $1,000. The grand prize for the fastest time will be $2,500 in addition to the class prize that goes with it. The distance of the race will be 25 laps of an 8-mile course laid out on the west side of the park. The police arrangements this year will be practically the same as they were last, when nearly 2,000 men guarded the course.

F. E. Edwards, chairman of the Technical Committee, will be in charge of the examination of the cars. Fred C. Dunlap will act as referee and Fred J. Wagner will line up and start the contestants.

Ford Wins Omaha Run

OMAHA, NEB., Sept. 18—A Ford car won the third annual *World-Herald* automobile run, under the auspices of the Omaha Motor Club. A Marion was second.

The Ford was entered and driven by Max Gottberg of Columbus, and the Marion was entered by the Marion Auto Company of Omaha. The prizes were $250 and $150, given by the *World-Herald.*

The four-day run, Sept. 12-15, was from Omaha to North Platte and return, a total of 666 miles.

The scores of the cars follow:

No.	Car.	Technical. Score.	Road Score.	Total.
5.	Ford	13	1	14
12	Marion	33	perfect	33
6	Velie	35	3	38
1	Lexington	25	17	42
27	Paige-Detroit	50	perfect	50
10	Maxwell	54	perfect	54
3	Ford	37	22	59
14	Alco	98	perfect	98
7	Chalmers	195	perfect	195
9	Case	139	57	196
4	Lion	192	17	209
16	Paige-Detroit	115	138	253

No. 8, a two-ton Kelly truck entered by Andrew Murphy & Son, made the complete trip in but little longer time than the touring cars, and with perfect road score.

Velie No. 6, which was penalized 35 points as a result of the technical examination, had but three demerits on the road.

Ford No. 2, entered and driven by Ed. Brown, sustained a cracked steering housing near Lincoln, but arrived in Omaha ahead of scheduled time. Aside from this it had few points against it, but was withdrawn from the contest. The other cars in the run were the Inter-State pilot car, the Inter-State official car, Hupmobile and Ford press cars.

Old Reliable, No. 26, prominent contender in 5,001 to 7,000 pound division

Seeks to Enjoin R. C. Hupp

DETROIT, MICH., Sept. 19—Following close upon the retirement of R. C. Hupp from the Hupp Motor Car Company, of Detroit, a bill of complaint was filed to-day by that company in the Wayne County (Mich.) Circuit Court, asking for a permanent injunction restraining Hupp and others associated with him in a new company called the Hupp Corporation from using the name "Hupp" in connection with the manufacture and sale of gasoline automobiles, or in any other manner that would injure the business of the Hupp Motor Car Company; and especially in connection with the manufacture of a small car which, according to announcement, is to be placed on the market by the Hupp Corporation.

The bill alleges that R. C. Hupp and brother, together with the Hupp Corporation, have violated the rights of the Hupp Motor Car Company by the use of the name "Hupp" in the automobile business, inasmuch as the Hupp Motor Car Company used that name at the request of Mr. Hupp when the company was incorporated, and has made the name well known to the trade and to the public in general; that the use of the name "Hupp" by Mr. Hupp in the new company, the Hupp Corporation, has been, and will be, a source of confusion and embarrassment to the Hupp Motor Car Company and its dealers, to manufacturers and the general public with whom it does business; and that such use of the name "Hupp" as already made on the part of Mr. Hupp and his associates in the company called the Hupp Corporation is an attempt to trade illegally upon and benefit by the reputation and standing of the Hupp Motor Car Company.

Moline Factory to Be Doubled in Size

MOLINE, ILL., Sept. 18—Contracts providing for the erection of three buildings have been let by the Root & Van Dervoort Engineering Company, a subsidiary concern of the Moline Automobile Company. This will double the output of the plant. Work on the new buildings has already been commenced. The company is far behind on orders, due to inadequate facilities and expansion was absolutely necessary. The new buildings are:

Assembling building, brick construction, one story high, lantern roof, block floor, ground dimensions 85 x 258.

Testing and painting building, ground dimensions 70 x 375, one story basement and floor of concrete construction, lantern roof.

Casting storage building, ground dimensions 70 x 80 feet, one story. After the new buildings are completed assembling work will be carried on in the new building for that purpose instead of the machine shop as is now the case. A large amount of new machinery has been ordered.

New Officials for Mais Company

INDIANAPOLIS, IND., Sept. 18—At a recent meeting of the stockholders of the Mais Motor Truck Company, H. W. Moore was appointed assistant treasurer. The directors appointed for the ensuing year are: John Saulter, Dr. A. E. Sterne, A. W. Markham, C. L. Chandler, W. H. Roberts and Albert Mais. President Brown contemplates establishing a school for drivers at the factory in the near future.

Promoters Must Protect Public

While no definite announcement of a change in sanctioning contests on dirt tracks has been made by the Contest Board, it is pretty generally understood that it will be exceedingly difficult to gain official recognition for such race meetings in the future.

For the events already sanctioned to be held on dirt tracks, the Contest Board is insisting that due precautions be taken to prevent any recurrence of such disasters as befell at Syracuse last week.

New York Commission, Director Page and Col. Sohier at top of Jacob's Ladder

Highway Experts Inspect Roads

REPRESENTATIVES of the road departments of New York, Massachusetts, Connecticut, New Hampshire, Washington and of the United States completed on Tuesday a three-day inspection of New York and New England road construction, under the auspices of the Touring Club of America. The party started from Albany Sunday morning and proceeded to Pittsfield and then to Springfield, Mass. On Monday they circled around Springfield and then went south to Hartford and Old Saybrook, finishing the day's run at Waterbury. On Tuesday local inspections were made and the tour was concluded.

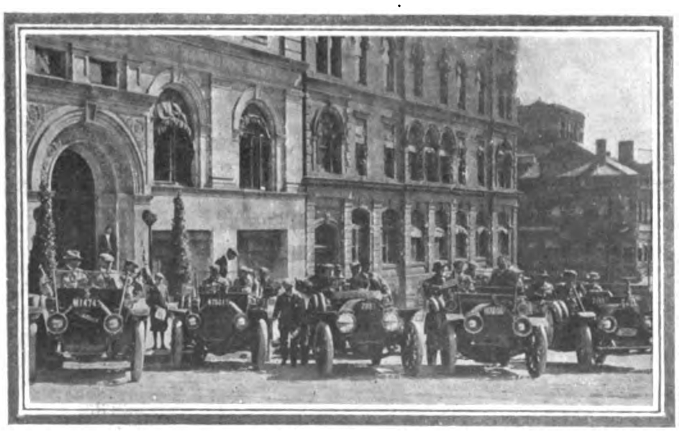
Banquets and informal discussions on practical, theoretical and actual road-building were held at Springfield, where the party was entertained at the magnificent New Kimball, and at Waterbury, where the road commissioners stayed at the Elton.

The purpose of the tour was not the interchange of ideas between the road authorities so much as bringing into personal contact the men who have charge of road improvements. A most astonishing condition was developed at the banquet held at Springfield, where, under the direction of Dr. Logan Waller Page, Director of the office of Public Roads of the Department of Agriculture, all the road commissioners and experts outlined present and past practice in their art and told of experiments and their result. Each speaker in taking the floor specifically denied that he had discovered the ideal road from the viewpoint of the user and stated that there was an element of doubt as to the utility of any of the various practices in use to-day.

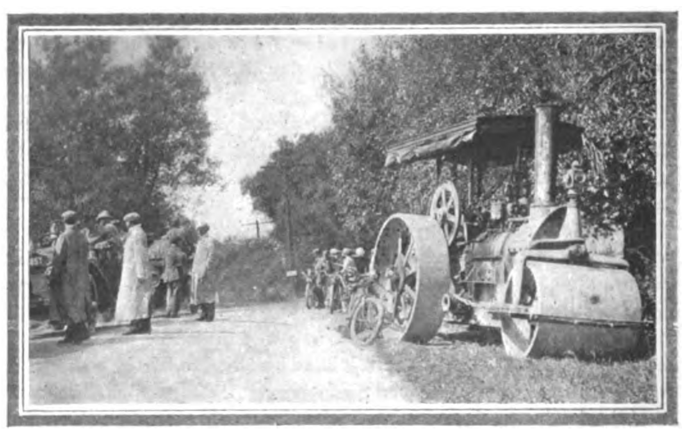
Commissioner Kemp, of Massachusetts, made a characteristic speech in which, after stating that he knew little of road building, he went on to give a detailed account of some of the Massachusetts roads in which he, as a member of the commission, has direct supervision. Mr. Kemp described the highway followed by the party from the New York State line, taking it mile by mile, and told how eight different types of roads were included in this short route. He said that each mile presented its own problem and that the same type of construction, used by the same volume of traffic, often produced widely different results, while different methods of road building always resulted in some variance of service, durability and maintenance cost.

He said that his State took little pride in the new road which has been constructed around "Jacob's Ladder," but indicated that the time is not far off when road-building will assume a more settled attitude. This, he said, was shown by the offer of one of the Massachusetts division engineers, who agreed to take the contract for maintaining the roads in his district and give a bond to insure this service for less than $400 per mile, per year. As a condition, this engineer required that the roads should be properly built and crowned and treated with a blanket preparation of oil and fine stone.

Mr. Kemp drew the unavoidable conclusion from his observations that automobile traffic does not wear out the roads with anything like the speed and certainty that follows horse traffic. He pointed out that on several stretches of highway where the crown was in the proportion of 3-4 of an inch to the foot, or more, so that the road was not usable for horse-drawn traffic,



The party leaving Hotel Kimball, Springfield, Mass., on Tuesday morning



Inspecting a new-laid road en route to Springfield, Mass.

Commissioners at luncheon stop in front of the Wendell, Pittsfield

Showing an ideal wide macadam driveway in the Berkshires

it stood up for years under the automobile travel, while other roads where the crown was not so pronounced, disintegrated, ravelled and were destroyed by the combined traffic.

Dr. Page presided over the session, which was addressed by Mayor Lathrop, Commissioners Sohier, Catlin, Hill, President Whiteside of the Stevens-Duryea company and numerous others of the tourists and local enthusiasts.

On Sunday the tour started from the Hotel Ten Eyck, Albany. Noon control was at the Wendell House, Pittsfield, Mass. On Monday the investigations were so prolonged in Massachusetts that the mid-day stop scheduled for Old Saybrook did not take place until late in the afternoon.

A fine banquet attended by about forty, was held at the Hotel Elton at Waterbury, at which Road Commissioner MacDonald, of Connecticut, made an interesting speech with regard to his sixteen years as a conserver and builder of roads.

The tour was a remarkable success in every way, the members making a careful study of road conditions, but best oi all becoming acquainted with one another so that in future there will be more exchanging of views and data, to the profit of motordom.

Great praise was extended to the Touring Club of America for its enterprise in bringing the road experts together and for its care in arranging the details of the trip.

The following took part in the tour: Logan Waller Page, Paul D. Sargent, United States Government; William H. Catlin, New York State Superintendent of Highways; John A. Bensel, State Engineer; Charles E. Treman, State Supt. Public Works; Gordon Reel, Highway Department; A. H. Rennie, T. C. A.; J. D. Barnhill, Treasurer T. C. A.; Henry MacNair, Blue Book; F. H. Elliott, Secretary T. C. A.

Massachusetts: Highway Commission: Harold Parker, William D. Sohier, Frank D. Kemp; L. J. Minahan, T. C. A.; William M. Kimball, T. C. A.; John A. Coulthurst, vice-president T. C. A.; Mayor E. H. Lathrop, William H. Whiteside, president Stevens-Duryea; H. C. Tenney, T. C. A.; W. M. Stevenson, T. C. A.; Albert E. Lerche, President Automobile Club of Springfield; H. A. Brooks, T. C. A.; C. P. City Sued for Oiling Streets

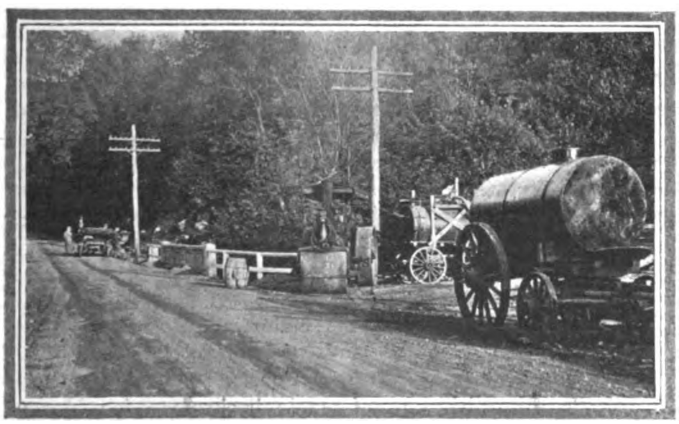
WALTHAM, MASS., Sept. 16—The question of whether a city or town has the right to oil its streets instead of watering them will be settled by the Massachusetts courts in the future as a result of a suit filed against Waltham on behalf of Mrs. Henry Endicott, of Boston. She was being driven through Waltham some time ago when her motor car skidded and she and her two children, her mother and the chauffeur were thrown out when the car struck a pole.

The contention is to be raised that the street had just been oiled, and that too much oil had been used, thereby making the roadway slippery and dangerous, and that through no fault of the driver the accident happened, but that the surplus of oil constituted a defect in the highway. The progress of the suit will be watched with interest by good roads advocates.

The accident happened at a curve and it is claimed that the motor car was running slowly, but it skidded so sharply it got beyond control of the chauffeur. All the occupants were injured, Mrs. Endicott sustaining a broken knee cap, her mother, Mrs. Francis P. Sears, was cut on the head and the children were bruised and unnerved. The car was badly damaged, too. The family is one of the most prominent in Boston society and so the case will be pushed.



Resurfacing old roadway with a coat of tar oil and stone screenings

The party leaving Stockbridge on the road to Lee, Mass.

Trade Is Booming at Detroit

DETROIT, MICH., Sept. 18—With the Studebaker Corporation adding another plant, to be known as No. 10, to its Detroit industrial group, with work well under way on the Continental Motor Manufacturing Company's extensive new factory out in the Fairview district, and with plans either completed or nearing completion for at least two more mammoth automobile plants in the north end, the local outlook for the immediate future of the industry is anything but discouraging.

The big event of the week in local motor circles was the purchase by the Studebaker Corporation, through Walter E. Flanders, general manager of the Detroit factories, of the Ford Motor Company's old plant on Piquette avenue, directly east of the No. 1 plant of the E-M-F division. This gives the Studebaker interests two square blocks in this vicinity and adds greatly to their facilities. The plant had been practically deserted for some time, the Ford Motor Company having abandoned it as an auxiliary factory. New machinery will be installed at once and the factory put in operation as soon as possible with a force of 1,000 men. As already indicated, it will be known as E-M-F plant No. 10.

With regard to the purchase, Mr. Flanders said: "Our only purpose in acquiring the old Ford plant is to facilitate the extensions of our business. We propose to build 50,000 cars for the 1912 season. Of these 30,000 will be the Flanders "20" and 20,000 the E-M-F "30." One of the main purposes in bringing our dealers from all over the country to Detroit is to show them that we are going ahead just as fast as we can in the work of increasing our facilities. Within 60 days we will be manufacturing 250 cars a day."

Ground was broken last week for the Herreshoff Motor Company's new factory on Woodward avenue, between Belmont and Trowbridge avenues, the site occupying an entire square. The property immediately adjoins Boston Boulevard, one of the most exclusive residence streets in the city.

The company aims to make the new plant, because of its prominent location, as attractive as possible, a model in fact. The separate administration building, fronting on Woodward avenue, will be of red brick and cement, with ornamental tiling in front and sides. The interior will be finished in white enamel and mahogany. This building will contain, besides the offices, spacious showrooms and a reception room for out-of-town customers. The factory will conform to the administration building in exterior appearance. The power plant will be separate from the rest of the institution and will be located in the furthest corner of the lot.

W. C. Durant, formerly head of the General Motors Company, and the "man behind" the recently organized Chevrolet Motor Company, is the reported purchaser of 40 acres of land on Woodward avenue, north of the car barns, in Highland Park, which was sold by the Highland Park Land Company last week. Mr. Durant will neither affirm nor deny the report, but it is taken for granted in motor car circles here that he is the buyer and that he has acquired the property for the Chevrolet Motor Company as a site for a factory. The price paid was about $160,000.

While its plans have been kept well under cover, it seems to be pretty generally understood by men in the business that the company is preparing to manufacture two models, a "four" and a "six," both of French design and right up to the minute in the matter of equipment.

The Highland Park Land Company, from whom the site for the Chevrolet plant is reported to have been purchased, is composed largely of men closely identified with the Ford Motor Company, including Henry Ford, James Couzens, H. H. Rackham and others.

Work on the big plant of the Continental Motor Manufacturing Company, on Jefferson avenue, just east of the Hudson plant, is progressing rapidly, and an effort will be made to have it in operation by January 1. From 1,000 to 1,500 men will be employed. It will comprise eight buildings and a power plant All of the buildings will be two stories high, except the machine shop (which will be a saw-tooth affair, 200 x 280 feet), and will be of steel and concrete construction, with steel sash. The factory at Muskegon will continue in operation, but the general offices of the company will be here. The present officers are: President and treasurer, B. F. Tobin; vice-president, R. W. Judson; secretary, H. J. Warner.

Detroit is to become the headquarters of the Mexico Latex Company, which manufactures rubber from the milk of the castilla plant. Louis F. Newman, of this city, is president.

A new sales company, known as the Marquette Company, has been organized as a subsidiary of the General Motors Company, and will handle the product of the Marquette Motor Company, manufacturing the Rainier and Welch-Detroit cars and the new Marquette. The officers are: Thomas Neal, president; O. C. Hutchinson, vice-president and manager; James T. Shaw, treasurer; Standish Backus, secretary; T. S. Merrill, assistant secretary and assistant treasurer. Headquarters have been established at 1302 Jefferson avenue. The merger of the Marquette Motor Company and the Welch-Detroit Company was announced some time ago.

A $1,000,000 company is being organized by Detroit and Lansing capitalists to manufacture a new motor fire chemical engine, the distinctive feature of which is that it pumps water from the mains like any other fire engine, the water being charged with a chemical as it passes through the engine. The engine, as designed, has a capacity of 350 gallons of chemicalized water per minute. A plant is to be erected either in Detroit or Lansing as soon as the organization plans are completed.

The directors of the General Motors Company have declared a dividend of 3 1-2 per cent. on the preferred stock, to be paid on October 2 to the stockholders of record on September 22.

At the annual stockholders and directors' meeting of the Abbott Motor Company, held last week, the officers were all reelected for the ensuing year, as follows: President, C. W. Jamieson; first vice-president, F. M. Knapp; second vice-president, H. M. Preston; secretary, Wade Millis; treasurer and general manager, M. J. Hammers; assistant general manager, B. C. Spitzley; sales manager, W. T. Bush.

Pullman Company Builds Taxi

YORK, PA., Sept. 18—The Pullman Motor Car Company has gone in the taxicab building business, and this new type of car has been added to its line of models. About thirty of these cars are for the Pullman Taxicab Company, Philadelphia, and six were shipped last week to the Quaker City. The cars will be mounted on a regular Pullman chassis, Model O, 30 horsepower.

Norwalk Company Settling Affairs

NORWALK, OHIO—The affairs of the Norwalk Motor Car Company, which have been in the hands of two receivers, appointed by the Common Pleas and Federal Courts, have now reached Attorney Ben B. Wickham, referee in bankruptcy for Huron county. The referee will call a meeting of the creditors to give them an opportunity to select a trustee.

907 Miles in 12 Hours

LONDON, Sept. 11—In a recent test carried out on the Brooklands track a particularly noteworthy feat was accomplished by the Sunbeam car. It consisted of driving a car fitted with a six-cylinder motor of 90-millimeter bore and 115-inch stroke (3 2-5 inches x 4 3-5 inches), for one round of the clock, averaging approximately 80 miles per hour. As a precautionary measure the tires were changed every two hours. It is estimated that the motor had to turn over at 1,800 revolutions per minute in order to attain the speed. The motor had the cylinders cast in two blocks of three, with all the valves placed on the same side, slightly inclined towards the combustion chamber.

The mixture was conveyed to the cylinders from the carbureter by means of a manifold bolted to the side of the motor opposite to that on which the valves are located, core-ways being cut in the cylinder casting, thereby heating the gases before being aspirated by the piston. Double distributor magneto with two sets of spark plugs were employed and the oil was fed to the various parts of the motor at a pressure of 30 pounds per square inch.

Power Fire Engines in Parade

YORK, PA., Sept. 18—The first automobile combined pump engine, chemical engine and hose wagon owned in Pennsylvania was one of the features of the large firemen's parade last Thursday in this city at the convention of the Pennsylvania State Firemen's Association. The fire apparatus is driven by a six-cylinder, 90-horsepower engine and has a speed of 60 miles an hour. The car cost $9,000.

H. G. Louser is chief of the Lebanon fire department which has the apparatus. There were three other automobile chemical apparatuses in line, one from Hose Company No. 3, Bristol, Pa., another from the Radnor Fire Company, Wayne, Pa., and the new chemical engine of the Reliance Fire Company, West York Borough. The latter was built by the Martin Carriage Company, York, Pa., and is the first in the local fire department. There were over 100 fire companies from different parts of the State, and over 7,000 men in the parade.

Detroit Sees First Show

DETROIT, Sept. 18—A most complete and attractive automobile show,is the one at the State Fair this year, opening today. Many of the local manufacturers, notably the Chalmers Motor Company and the Warren Motor Car Company, are showing their complete lines for 1912. The commercial car interests are also well represented.

One of the interesting exhibits is the Colonial electric, manufactured by the newly organized Colonial Electric Company, of this city. The car on exhibition is the first one completed and is being shown for the first time. Its distinctive features are an unusually long wheelbase and an extra width of body. It is of the five-passenger brougham type, with semi-elliptical springs forward and full elliptical in the rear. It has a bevel-gear shaft drive with full floating type rear axle and a Westinghouse motor and controller. The car is richly upholstered in dark blue broadcloth.

The new Chalmers "Thirty-six," which made its appearance about two months ago, is featured in the Chalmers exhibit. This car is shown in both fore-door touring car and fore-door pony tonneau types.

Other exhibitors are: The Annette Automobile Garage, Jackson Automobile Company, Cole Motor Sales Company, Cunningham Automobile Company, showing the Flanders electric, E-M-F "Thirty" and Flanders motorcycle; Rapid Motor Vehicle Company, Brush-Detroit Motor Company, Pratt-Carter-Sigsbee Company, Detroit Hupmobile Sales Company, Detroit Motor Wagon Company, Commerce Motor Car Company, Elmore Automobile Company, Brady Automobile Company, showing the Hudson line; Day Automobile Company, Lion Motor Sales Company, General Motors Company, Abbott-Detroit Automobile Company, Cartercar Automobile Company, Regal Automobile Company, Oakland Automobile Company, Poss Motor Company, Grant Bros. Automobile Company, Cadillac Motor Car Company, Buick Automobile Company, Overland Automobile Company, United Motor Detroit Company, showing Columbias and Maxwells; Seitz Motor Truck Company, Mitchell-Lewis Company, Flanders Manufacturing Company, Pontiac; W. A. Patterson Automobile Company, Miller Motor Car Company, Foster Motor Sales Company and the White Motor Company.

Calendar of Coming Events

Shows, Meetings, Etc.

Sept. 25-30........Atlantic City, N. J., Convention and Exhibition of the Carriage Builders' National Association.
Jan. 1-5, 1912......New York City, Grand Central Palace, Annual Show, Automobile Manufacturers' Association of America.
Jan. 6-13..........New York City, Madison Square Garden, Twelfth Annual Show, Pleasure Car Division, Automobile Board of Trade.
Jan. 6-20..........New York City, Madison Square Garden, Annual Show, Motor and Accessory Manufacturers.
Jan. 10-17........New York City, Grand Central Palace, Twelfth Annual Show, National Association of Automobile Manufacturers; also Motor and Accessory Manufacturers.
Jan. 15-20.........New York City, Madison Square Garden, Twelfth Annual Show, Commercial Division, Automobile Board of Trade.
Jan. 18-20.........New York City, Annual Meeting of the Society of Automobile Engineers.
Jan. 27-Feb. 10....Chicago Coliseum, Eleventh Annual Automobile Show under the auspices of the National Association of Automobile Manufacturers. Pleasure cars, first week. Commercial vehicles, second week. Accessories, both weeks.
March 2-9.........Boston, Mass., Tenth Annual Show, Boston Automobile Dealers' Association, Inc.

Race Meets, Runs, Hill-Climbs, Etc.

Sept. 21-22........San Francisco, Cal., Commercial Reliability Run, San Francisco *Examiner*.
Sept. 23...........Philadelphia (Point Breeze), Track Races, Philadelphia Automobile Trade Association.
Sept. 23-25........Detroit, Mich., Track Races, Michigan State Agricultural Society.
Sept. 30...........Guttenburg, N. J., Track Races.
Sept. 30...........Bridgeton, N. J., Track Races, South Jersey Motor Club.
Sept. 30...........Flint, Mich., Track Races.
Oct. 6-13..........Chicago, Ill., Thousand-Mile Reliability Run, Chicago Motor Club.
Oct. 7.............Danbury, Conn., Track Races, Danbury Agricultural Society.
Oct. 7.............Philadelphia, Fairmount Park Road Races, Quaker City Motor Club.
Oct. 7.............Springfield, Ill., Track Races, Springfield Automobile Club.
Oct. 9-13..........Denver, Colo., Reliability Run, Denver Motor Club.
Oct. 10............Bedford, Ind., Hill Climb.
Oct. 11............Oklahoma City, Okla., Reliability Run, Oklahoma State Automobile Association.
Oct. 12-13.........Peoria, Ill., Track Races, Peoria National Implement and Vehicle Show.
Oct. 14............Santa Monica, Cal., Road Races.
Oct. 14 (to 25).....New York City, Start of the Annual Glidden Tour, en route for Jacksonville, Fla.
Oct. 16-18.........Harrisburg, Pa., Reliability Run, Motor Club of Harrisburg.
Oct. 21............Atlanta, Ga., Track Races.
Oct. 31............Shreveport, La., Track Races, Shreveport Automobile Club.
Nov. 1.............Waco, Tex., Track Races, Waco Auto Club.
Nov. 2-4...........Philadelphia, Reliability Run, Quaker City Motor Club.
Nov. 3-4...........Columbia, S. C., Track Races, Automobile Club of Columbia.
Nov. 4-6...........Los Angeles-Phoenix Road Race, Maricopa Auto Club.
Nov. 9.............Phoenix, Ariz., Track Races, Maricopa Automobile Club.
Nov. 9, 10, 12.....San Antonio, Tex., Track Races, San Antonio Auto Club.
Nov. 27............Savannah, Ga., Vanderbilt Cup Race, Savannah Automobile Club.
Nov. 30............Los Angeles, Cal., Track Races, Motordrome.
Nov. 30............Savannah, Ga., Grand Prize Race, Savannah Automobile Club.
Dec. 25-26.........Los Angeles, Cal., Track Races, Motordrome.

Foreign Fixtures

Oct. 1.............Gaillon, France, Hill-Climb.
Oct. 12-22.........Berlin, International Automobile Exhibition.
Nov. 3-11..........London, Eng., Olympia Show.

Expert Reports on Aluminum

WASHINGTON, D. C., Sept. 18—Not over a generation ago aluminum was little more than a curiosity. It was worth $15 a pound and its total production in the United States was less than 100 pounds a year, notwithstanding the fact that aluminum is the most abundant of all the metals in the earth's crust, of which aluminum oxide forms about 15 per cent.

The great progress made in the industry is noted in the fact that a report on bauxite and aluminum for 1910, just published by the United States Geological Survey, shows a consumption in this country in that year of 47,734,000 pounds, valued at nearly $12,000,000. The price has dropped from $1 an ounce to about 23 cents a pound.

W. S. Phalen, author of the report, states that although aluminum has in recent years become a most important economic metal, it is at present produced only from bauxite, a comparatively scarce mineral, and that even the great discovery which made this possible is only the first stage of wresting the metal from its various rock and earth combinations. Aluminum is an essential constituent of all important rocks, except sandstone and limestone, and is found in all clays. The supply is therefore practically limitless, awaiting only the perfection of a process for cheap extraction.

There are a number of recently patented processes which show progress in the cheap extraction of the metal from the common sources of supply.

Colonels Must Show Double Numbers

LOUISVILLE, Sept. 18—An opinion from the Attorney-General of Kentucky has been received by the Louisville Automobile Club on the disputed question of numbers on automobile lamps. The Attorney-General quotes the last half of Section 4, Chapter 81, of the Acts of 1910, which act is entitled "An act defining motor vehicles, providing for the registration of the same and uniform rules regulating the use and speed thereof," which reads as follows:

"Upon each of the glass fronts of the two first mentioned lamps showing white lights shall be displayed in such manner as to be plainly visible when such lamps are lighted, the number of the certificate issued aforesaid by the Secretary of the State, and in addition thereto the letters 'KY,' such figures to be in separate Arabic numerals not less than 1 inch in height."

"My opinion," says the Attorney-General, "is that this section of the statute is mandatory and that every owner or person using or operating an automobile upon the public highways, streets, etc., of the State or any city must comply with the provisions of Section 4 of the act. In view of the provisions of Section 3, which seem to fully provide for the identification of the car, the requirements of Section 4 seem to be superfluous, but thus the law is written, and so long as the statute remains unrepealed, or until amended, it should be obeyed by those owning and operating automobiles."

Indianapolis Seeks City Automobiles

INDIANAPOLIS, IND., Sept. 18—After considerable deliberation, the Indianapolis Board of Public Safety has awarded contracts for four new pieces of motor fire apparatus for the fire department. These contracts are as follows:

Squad wagon, carrying eight men, 250 feet of chemical hose and 35-gallon chemical tank, Meridian Auto Company, representing Packard Motor Car Company, $5,277.40; ladder truck, carrying 130 feet of ladders, Mais Motor Truck Company, $4,800; combination hose and chemical wagon, $5,000, and pump engine pumping 600 gallons of water a minute, $7,500, to American Le France Engine Company, Elmira, N. Y.

The board of school commissioners has received the following bids on a truck for the school supply department: Mais Motor Truck Company, chassis, $2,500; J. E. Burkhart, representing General Vehicle Company, 2,000-pound truck, $2,700 and $3,390, according to batteries; 4,000-pound truck, $3,450 and $3,820, according to batteries.

Thomas A. Winterrowd, building inspector, has asked the Board of Public Safety to buy two gasoline runabouts for the deputy building inspectors under him. The Board of Health is asking bids on a new gasoline ambulance for the city hospital, which already has one such ambulance in service.

Motorizing Lansing's Fire Fighters

LANSING, MICH., Sept. 18—It is expected that by January 1 Lansing will have a fire department consisting almost entirely of automobile apparatus. The Board of Police and Fire Commissioners has decided to make the combination wagon at station No. 4 into an automobile combination truck. The board has taken similar action in regard to the combination wagon at station No. 3. The work will be done by the Olds Motor Works.

This will leave only one piece of horse-drawn apparatus in the whole department and that probably will be supplanted shortly.

Trunk Line Will Tap Desert Country

PORTLAND, ORE., Sept. 18—Burns, Ore., and the city of Portland are to be brought eight days nearer together, and Portland given a lever which should mean the securing of the immense central Oregon business as the result of the establishment of automobile freight truck service between the cities of Bond and Burns, Ore. The total distance over which the big freight trucks will run is 138 miles, practically all of which i over a desert country, as accessible in the Winter as in Summer.

Negotiations pending for some time between the merchants of Burns and the Central Oregon Trucking Company, of which Clifford C. Harrison, of Portland, is the head, were brought to a close the past week. Practically all of the freight received by the Burns merchants will now be routed through Bond, and thence over 138 miles of desert country into Burns.

Will Race This Week at Hartford

HARTFORD, CONN., Sept. 18—After having been indefinitely postponed, the auto races which were to have been held at Charter Oak Park September 9 and which were called off on account of a muddy track, will be held September 21, the Automobile Club of Hartford having decided to promote them.

The races were arranged by the Connecticut Fair Association as the closing feature of the State Fair held Labor Day week.

Reo Company Plans Big Production

LANSING, MICH., Sept. 18—According to General Superintendent Richard H. Scott of the Reo Motor Car Company a conservative estimate is that the production of the 1912 model will amount to 9,000 cars.

The capacity of the Reo plant is 1,000 cars a month, but that capacity cannot be reached in October, November or December. But by January the company hopes to have its raw material pushed far enough along through the various departments so that the capacity of the factory will be reached. For eight months the departments will be operated to their full extent. During some of these months it is expected the factory will exceed its normal capacity.

Insurance Company Fights Bar

DES MOINES, IA., Sept. 18—The American Fidelity Company, an insurance concern with headquarters in Montpelier, Vt., has filed suit against John Bleakly, auditor of State of Iowa, asking that the auditor be restrained from preventing the company from operating in Iowa its business of insuring automobile owners against injuries in accidents, and being made defendant in damage cases.

Tire Situation in Great Britain

AUTOMOBILE tire manufacturers in America may profit by digesting the following points relative to the motor car in the United Kingdom: First, the popularity and usefulness of and, consequently, the increased demand for taxi motor cabs are potent factors in the life of Britishers, for these taxis are rapidly taking the place of the horse-drawn hansom cab even in the remotest corners of Great Britain. This not only means more taxi-cabs and automobiles, but a corresponding increase in the demand for tires. Secondly, there is a growing market for the freight automobile throughout the United Kingdom. Third, it is evident that American automobile manufacturers are daily increasing their exertions relative to the acquirement of a share of the British motor car and tire trade. These facts have awakened the people to a sense of the really good quality of the American-made automobile and they are beginning to talk about the product in a favorable spirit. But shall they assert that the American manufacturer would sell more machines and tires if he were to emulate the trade methods of the British and even of the Continental European manufacturer and merchant, who make it the invariable rule to advertise extensively, insist strenuously upon being represented at all of the motor car shows, and to so conspicuously display their products that they shall at all times be within view of the public. Frequently, the outlay involved is prodigious, but the British manufacturer contends that expenditure of capital is imperative if he would keep in the limelight with his competitors. The same policy is incumbent upon the American manufacturer who would get his motor cars or tires before the eyes of the people. The head display agencies for British and Continental European-made cars are London and Manchester, sub-agencies being maintained in the smaller Provincial cities, such as Leeds, Liverpool, Birmingham and even Southampton. But so far as the manufacture of rubber tires is concerned, Manchester is the British center. Not alone are English firms in this line eminent, but all of the leading Continental European manufacturers of tires maintain depots in Manchester for the display of their product. While American-made tires and automobile accessories are sold to some extent in the vicinity of Manchester, none of the American manufacturers have depots there, they apparently regarding London a sufficiently near-of-access goods depot from which to supply the trade of the middle counties.

The proper way for American manufacturers to secure a share of the British tire trade would be to establish a headquarters, say, in London, where, provided a great variety of goods was displayed, orders could be filled promptly. Sub-agencies in Manchester and Liverpool might do well. But when a dealer carrying on business in a provincial town finds himself in need of automobile accessories, London is first in his mind. Therefore, local agents in towns like Leeds and Sheffield might not prove to be any material benefit to the manufacturer, except under special conditions. For example, Sheffield local dealers are supplied from the manufacturer's agent, or from the manufacturer direct with a stock sufficiently large to accommodate the trade in the immediate vicinity. Settlement is made for all goods sold at the end of each month. Twice during the twelve months an account of stock is taken. Upon these occasions slow-selling goods are exchanged at the London headquarters, the manufacturer giving ready-sale stock in its place. American-made tires are not as much in demand in Sheffield as are French and British-made tires. French manufacturers have established headquarters in London. British manufacturers are experimenting daily in order to find out if possible a tire which will run without the danger and the terrorizing effect of the side slip. And there is nothing that is quite as slippery as London's South American red-cedar paved streets on a dirty day. To this end a new disposition of rubber and steel is used in the tire. The finest grade of Para rubber is employed, forming a tread containing a network of the finest steel fiber; which resembles hairs. This combination produces a tread whose resiliency equals that of rubber alone, while it is also said to be practically impenetrable. It contains a non-skid surface, which causes it to adhere to the roadbed.

Discounts, as allowed by various manufacturers in Great Britain, differ considerably, ranging all the way from 10 to 50 per cent., as an inducement for pushing sales of automobiles and accessories. A rebate, in addition to the ordinary cash discount and based upon the amount of business transacted, is made at the end of the season, in the event of the terms of the contract regulating the sale price to the public not having been violated. A leading Continental European manufacturer is credited with allowing from 10 to 20 per cent. along the same lines of sale as stated.

In Edinburgh and vicinity local agents of British manufacturers of tires supply the automobile trade. Foreign manufacturing companies are represented by agents who serve in the capacity of distributors in London. Motor cars in Scotland are sold by firms who deal in automobiles and accessories. Agents handle the products of numerous manufacturers. There are nine firms in Edinburgh selling one particular type of British-made motor car tire. Commercial travelers sent out by British manufacturers are to be met with in all sections of the United Kingdom, going among dealers soliciting trade. The manufacturers supply the tires and every thirty days the stock is checked up until at the end of six months or twelve months the manufacturers take back the stale stock, replacing it with fresh goods. Catalogues contain but one price for each article listed, and upon this price to the trade all discounts are based. A 25 per cent. discount on list prices, 5 per cent. on cash sales (payment within seven days is regarded as cash) or 2 1-2 per cent. at thirty days are the prevailing terms.

Scotland has shown a kindly disposition toward French and German manufacturers of rubber tires, the sales of which are on the increase, while American-made tires also receive favorable comment, although the latter have not been as extensively displayed as the custom of the country calls for. In order to get a foothold it is necessary that goods should be placed with local agents or factors, and the terms of sale must need be quite as favorable as those which are granted by French, German and British makers, the latter controlling a goodly portion of the Scotch trade in tires, as well as in automobile accessories. The British firms expend for advertising such sums as the importance of the market warrants.

Acetylene Lamps in Winter—Since lamps are used much less frequently in Winter than in the regular touring season, they are often neglected, the generator being left with stale or partially used carbide in the chamber, and the residue being allowed to clog up the water port and the waste ports. The rubber lamp connections and gasbag suffer also by deterioration as well as the burners and gas valves. For the proper maintenance of the system, strict cleanliness should be maintained at all times and the various parts should be examined and replaced from time to time as necessary. The results of neglect are seen every spring in lime deposits which have to be removed by means of a cold chisel, in porous connections and in clogged burners which resist the cleaning wire and necessitate the scraping of the burners.

Up the Shenandoah

WITH the approach of cool weather there seems to be a tendency on the part of the compasses of motor tourists to point southward. Although little pleasure travel has as yet headed for the extreme South, many motorists have cast an attentive eye upon the Virginias at, say, a point approximating Hot Springs.

Travelers from New York City who contemplate such a tour may well go via Morristown, Easton, Reading and so on, as is very graphically represented in the trunk line chart which is one of the unique features of the *Automobile Blue Book*. Volume 3, covering New Jersey, Pennsylvania and the Southeast, should be used on this trip.

Tourists from Pittsburgh and the West may well follow the trail of the *Blue Book* official scout who went directly south from Cumberland on a very nice shale road to Monterey and then crossed the mountains on a fairly good dirt road which is being improved. The trip is delightful and the scenery such as to arouse enthusiasm. This trip is 88 miles shorter for tourists from the Pittsburgh section, who might otherwise go by way of Winchester and Staunton to Hot Springs.

Whichever way the tourist approaches the region, let him recall the fact that he traverses one of the richest fields of history in America. This statement does not apply particularly to the battlefield of Gettysburg and the many scenes of Civil War conflict. This is also the great region of colonial activity.

How true this is appears when one remembers that Philadelphia was the leading city of the country in the early days. All roads led to Philadelphia. All the colonists who started west long before Horace Greeley was alive to point the way made their exit from the coast and entrance into the great beyond by way of Lancaster and Bedford, or Cumberland and Uniontown. These places bore different names in those days. When General Braddock planned the road that bore his name, or when Forbes' Road took the all-Pennsylvania route to the strategic point of Fort Duquesne, settlements were few and far between. Indian trails fit only for pack trains were the chief "highways."

That the old "National Highway" of this section should have marked the beginning of the good roads movement in this country is also not without significance. The time is coming very shortly when this section will reassert its interest in good highways. Pennsylvania has been very devoted to the Cumberland Pike and is making considerable improvements. Virginia has evidenced an awakening in this respect also, especially in the vicinity of Richmond. The work of the Touring Club of America in connection with the American Association for Highway Improvement is already bearing fruit; and the Good Roads Congress to be held at Richmond the week of November 20-24 will focus public attention upon this very important subject.

Undoubtedly, this region will one day rival New England as an automobile touring ground. It is crowded with scenes of varied interest. Nature here is ever attractive. The coast is bordered by a wide belt of rich agricultural land. Up to the foothills

Valley to Hot Springs

of the mountains sweep the fields of grain; and then the vast mountain ranges rise in great billows from the Blue Ridge to the Ohio.

At the present time fords constitute one of the chief obstacles to completely satisfying motor travel in Virginia. The route to Hot Springs via Monterey, for instance, has some fords that might be bad in very wet weather. Nor can one deny that there are such well-known features as ditches and waterbars, but they are not bad. The 150 odd miles are covered on a good dirt road and the scenic delights make the trip in itself well worth taking.

From Cumberland one goes 13.1 miles to Frankfort, crossing the iron bridge over the Potomac River, 7.8 miles beyond. There are several sharp curves in the next score of miles, also several iron bridges and several small hamlets. The inhabitants of these queer places are just beginning to appreciate the increasing volume of motor travel, and, if there be any value in modern civilization, will quickly gain the polish that has already begun to shine in the small towns of the North. It is an undoubted fact that the growth of motor touring has brought many a village into the current of modern life, from which it dropped when the stage coach stopped and the railway went some other way.

Petersburg is entered on Keyser avenue. Crossing the long iron bridge, the traveler comes to a winding, hilly road from which the views are splendid. When the odometer reads 103 or thereabouts the route crosses the Virginia State line, shortly winding through the virgin woods. Monterey and Vanderpool are reached in quick succession. Monterey is 112 miles from Cumberland. Hot Springs is 36 miles beyond. At Warm Springs (143.5) one strikes a stretch of macadam, and 4 miles farther is a tollgate, which it costs a quarter to pass.

One has now reached the wonderful thermal springs, known all over the world and annually visited by many wealthy people. The valley is from 2,000 to 2,500 feet above the sea level.

The return trip to the northward should not be begun without remembering that to the south between Lexington and Roanoke is the Natural Bridge, 215 feet high, 100 feet wide and 90 feet clear span. Many prominent men before you have visited the bridge, including George Washington, who just naturally carved his name high up on the rock.

Another great natural wonder of this region is the Luray Cavern, reached over fair roads east from New Market on the route from Staunton to Winchester. It is a wonder spot rivaling the Kentucky Mammoth Cave. En route to Staunton, the tourist should take advantage of the new bridge over Cow Pasture River. As the pictures indicate, the views are very pretty, and the travel is better and 6 miles shorter. The National Highway is in fine shape to Winchester and to Hagerstown, according to official reports just received by the Touring Club of America. Road conditions in many parts of the country vary almost as the weather varies, so that the tourist should get the latest information before he starts.

Stresses and Strains in Tires

Part II.

Translation from an article by Henri Petit, in La Technique Automobile et Aérienne

THE warp and the woof threads in pneumatic tires are placed at an angle of approximately 45 degrees in the principal plane of the surface. As the resistance of the canvas is none other than that of the warp and the woof it is interesting to look for the resistance imposed on the threads.

In articles that have appeared on the manufacture of tires we find that the angle of the threads, which is about 90 degrees at the bead, comes down to 70 degrees at the center portion of the tire.

It is proposed to first of all calculate the tensions following the principal planes at the points A and C in Fig. 1.

Supposing the tire is cut in a meridian plane. The layers will have to withstand a resistance as follows in order to remain stuck together:

$$\frac{p.\pi r^2}{2\pi r}.$$

which equals $\frac{pr}{2}$.

This is the tension in the equatorial plane which can be designated by T_E.

If we now cut the tire in the equatorial plane the force which will tend to sever the two halves will be equal to

$$p\,[\pi\,(R+r)^2 - \pi\,(R-r)^2]$$

that is to say,

$$4\pi R r p$$

The tension for unity of length along the equatorial circle of the greatest radius will be:

$$T_M \text{ Min.} = \frac{4Rr\pi}{2\times 2\pi\,(R+r)}\,p = \frac{Rr}{R+r}\,p$$

and the tension for unity of length along the small circle will be:

$$T_M \text{ Max.}\frac{4\pi R r}{2\times 2\pi\,(R-r)}\,p = \frac{Rr}{R-r}\,p$$

Let these meridian tensions be called T_M Min. and T_M Max.

Near the beads the threads of the canvas are at an angle of 45 degrees to the direction of meridian and equatorial tensions.

The tension t following these threads will be (see Fig. 2):

$$t = \frac{\sqrt{2}}{2}\,(T_E + T_M \text{ Max.})$$

that is,

$$t = \frac{\sqrt{2}}{2}\,p\,r\left(\frac{1}{2} + \frac{R}{R-r}\right) = \frac{p\,r}{2\sqrt{2}}\;\frac{3R-r}{Rr}$$

At a point of the great equatorial circle where the threads form between them an angle α ($\alpha < 90°$) the tension of these threads will be, according to Fig. 3,

$$T = \frac{1}{2}\left[\frac{T_M}{\cos\frac{\alpha}{2}} + \frac{T_E}{\sin\frac{\alpha}{2}}\right]$$

that is,

$$T = \frac{1}{2}\,p\,r\left[\frac{R}{R+r}\;\frac{1}{\cos\frac{\alpha}{2}} + \frac{1}{2\sin\frac{\alpha}{2}}\right]$$

Let us apply these formulæ to some standard sizes of covers.

1° 760 × 90 $R = 33.5$ $r = 4.5$

Tension at the Bead of the Cover

$$t = \frac{5\times 4.5}{2\sqrt{2}}.\frac{33.5\times 3 - 4.5}{29}$$

= 26.5 kilogrammes approximately.

The tension at the running tread [angle of the threads α = about 80°].

$$t = \frac{5\times 4.5}{2}\left[\frac{33.5}{38\cos 40°} + \frac{1}{2\sin 40°}\right]$$

= about 21 kilogrammes.

The tension is appreciably less at the thread, as can be seen.

This explains why when a tire bursts (unless the burst is due to a cut) the tear generally takes place at the side wall. Near to the point of attachment, where the tension is greatest, the tire is reinforced by the two small layers. Generally the tire bursts just below these layers.

The tensions that have just been calculated show what is supported by the general body of canvas.

Each layer is subjected to n times less tension.

For the sake of argument we will suppose the tension on all the layers to be equal, as this is what makers strive for in making the tires.

For the example taken above of a 760 × 90 tire the tension is supported by at least four layers of canvas.

Near the rim the two layers must be taken into consideration as well and the total tension divided by 6.

$$\frac{26.5}{6} = 4.5 \text{ kilogrammes.}$$

Canvas of good quality should not break unless submitted to an effort of 56 kilos per square centimeter. The coefficient of security is therefore 12.

Another interesting point is at what part of a tire the work of each layer of canvas is greatest, granted that their number is variable.

Near the point B in Fig. 1 it can be seen that the tensions in the main planes are respectively.

Tension in the perpendicular plane to the meridian:

$$t = T_E = \frac{p\,r}{2}$$

Tension in the meridian plane:

$$T_M = \frac{p.2\pi R \times 2r}{2 \times 2\pi R} = pr$$

The angle that the threads make being ^{a} at this point, the forces that will act upon them can be expressed by (Fig. 3)

$$T = \frac{1}{2}\left[\frac{T_M}{\cos\frac{a}{2}} + \frac{T_E}{\sin\frac{a}{2}}\right]$$

continuing to call T_E the tension in the main plane perpendicular to the meridian plane.

But in replacing T_M and T_E by their values

$$T = \frac{1}{2}pr\left[\frac{1}{\cos\frac{a}{2}} + \frac{1}{2\sin\frac{a}{2}}\right]$$

The angle of the threads for the 760 × 90 tire that we have chosen is, for example, about 85 degrees.

From which the value of T:

$$T = \frac{1}{2} \times 5 \times 4.5\left[\frac{0.737}{1} + \frac{1}{2 \times 0.676}\right]$$

= about 22.5 kilogrammes.

This tension is not much greater than that which exists at the rolling tread.

At the point B (in Fig. 1) the number of layers of canvas is only 4. The tension of each thread of the canvas has a value

$$\frac{22.5}{4} = 5.5 \text{ kilogrammes.}$$

More, therefore, than the tension of the bead.

The tension increasing when a displacement is made from B to C, it can easily be seen that the tension of each stand or thread will be maximum following along the border of the bead strip.

This is borne out by practice. When a tire bursts prematurely it generally takes place at this point

II° 820 × 120 tire $R = 35$ $r = 6$.

$$\frac{R}{r} = \text{about } 6.$$

In applying the formulæ we have:

1. *Tension at the bead for the entire canvas structure* ($p = 6$ *kilogs.*).

$$t = \frac{pr}{2\sqrt{2}}\;\frac{3R - r}{R - r} = 44 \text{ kilogs.}$$

which for each layer equals:

$$\frac{44}{8} = 5.5 \text{ kilogs.}$$

taking the side strip into consideration.

2. *Tension at the running tread* ($a = 70°$)

$$t = \frac{1}{2}pr\left[\frac{R}{R+r}\;\frac{1}{\cos\frac{a}{2}} + \frac{1}{2\sin\frac{a}{2}}\right]$$

with

$$\cos\frac{a}{2} = 0.819$$

$$\sin\frac{a}{2} = 0.574$$

$$t = 34.5 \text{ kilogs.}$$

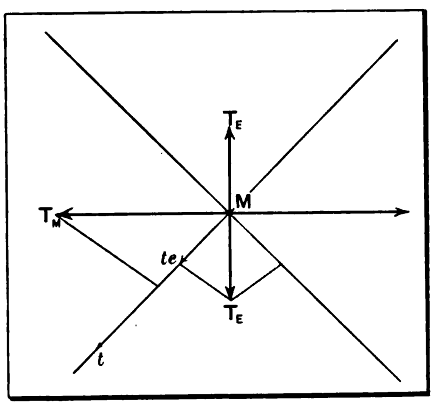

Fig. 2—Diagram showing the tension of the threads at a 45-degree angle

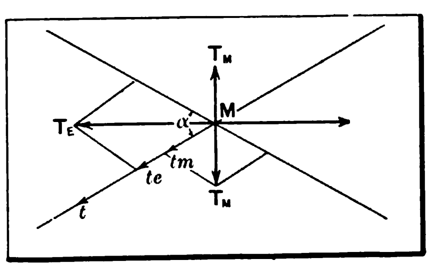

Fig. 3—Diagram showing tension of the threads at an angle less than 90 degrees

3. *Tension at the walls* ($a = 80°$).

$$T = \frac{1}{2}pr\left[\frac{1}{\cos\frac{a}{2}} + \frac{1}{2\sin\frac{a}{2}}\right]$$

with

$$\cos\frac{a}{2} = 0.766$$

$$\sin\frac{a}{2} = 0.643$$

$$t = 38 \text{ kilogs.}$$

Which is equivalent for each thread:

$$\frac{38}{6} = 6.3 \text{ kilogs.}$$

III. 935 × 135 tire

$$R = 40 \quad r = 6.8 \quad \frac{R}{r} = 6$$

1. *Tension at the bead* ($p = 7$ kilogs.).

$$t = \frac{pr}{2\sqrt{2}}\;\frac{3R - r}{R - r} = 57 \text{ kilogs.}$$

which is equivalent for each stand $\frac{57}{9} = 6.33$ kilogs.

2. *Tension at the running tread* ($a = 70°$).

$$t = \frac{1}{2}pr\left[\frac{R}{R+r}\;\frac{1}{\cos\frac{a}{2}} + \frac{1}{2\sin\frac{a}{2}}\right]$$

with

$$\cos\frac{a}{2} = 0.819$$

$$\sin\frac{a}{2} = 0.574$$

$$t = 4.55 \text{ kilogs.}$$

3. *Tension at the walls.*

$$t = \frac{1}{2}pr\left[\frac{1}{\cos\frac{a}{2}} + \frac{1}{2\sin\frac{a}{2}}\right]$$

with

$$\cos\frac{a}{2} = 0.766$$

$$\sin\frac{a}{2} = 0.643$$

$$t = 50.25 \text{ kilogs.}$$

which for each thread equals

$$\frac{50.25}{7} = 7.2 \text{ kilogs.}$$

It will be seen from the foregoing that the tension for each thread proportionately increases with the increase in diameter of the tire. But in all cases the coefficient of security remains superior to 8.

(*To be continued.*)

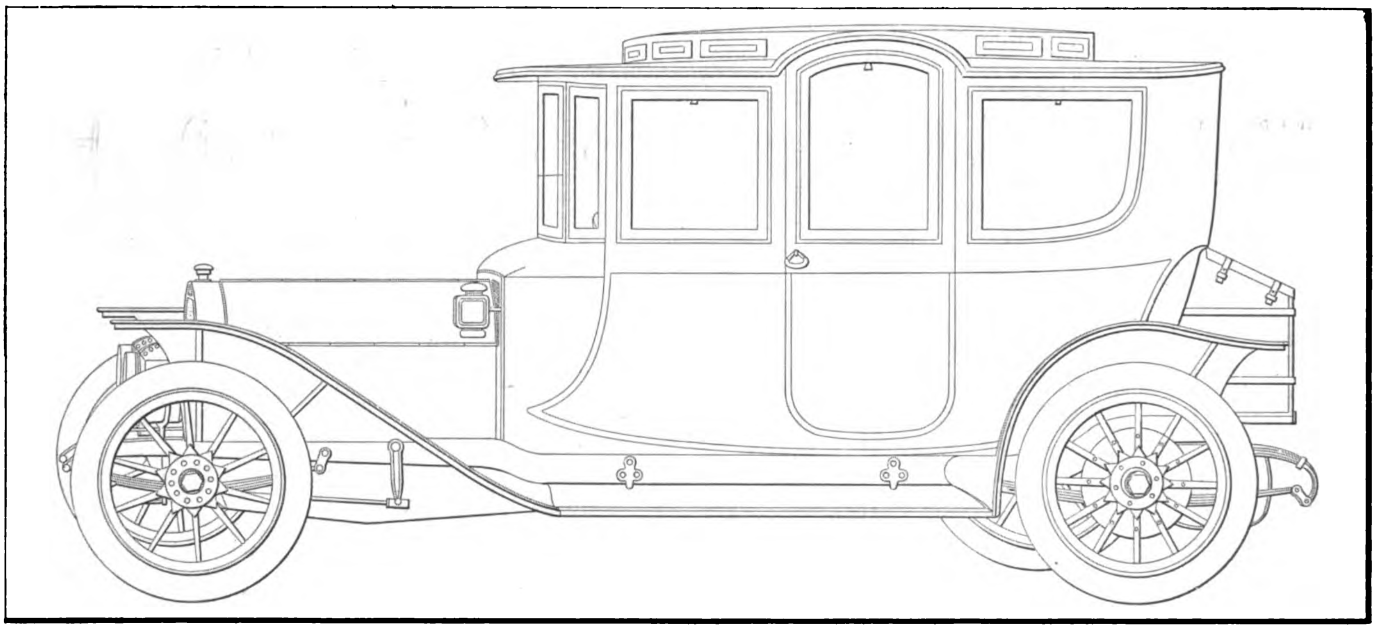

Fig. 1—Illustrating a new design of single-compartment limousine, showing generous proportions of arched door and maximum inside height

New Single Compartment Limousine

By George J. Mercer

THE maximum amount of comfort for the occupant should seem to be the slogan of the automobile body designer, if one would form his deductions from the appearance of the new designs of bodies that are coming out for Fall and Winter use. There is a general tendency to increase the thickness of the upholstery wherever possible and particularly in the seat cushions, which are not only made thicker but are being made with more slope toward the rear. There are novelties in appointments and in trimming designs, the addition of fore doors for the protection of the driver and the low-hung chassis with the drop center that allows of low entrance way are here.

Chief among the conveniences, or more properly speaking one of the necessities of a well-designed body, is the provision made for generous door width and ease of entrance and exit. These should be such as to suit the widest range of persons, and particularly those that occupy the rear seats of the car.

Figs. 1, 2, 3, 4 and 5 illustrate a new design, single-compartment limousine, having accommodations for seven passengers and in which the entrance way is ample and commodious. These five illustrations show a body with arched doors and ventilator dome in the roof. Both of these features have individually found favor with the public and their use collectively, as here illustrated, makes possible the maximum height for door entrance and also the maximum standing height inside the body, without distorting the body dimensions or taking from the general attractiveness of the design. The actual gain in height is 3½ inches in this instance and it is possible to make still further gain if it were required.

Fig. 1 illustrates the body with a slight perspective and mounted on a low-center chassis, having the gasoline tank at the rear, below, and the drive is on the left side. The trunk compartment is shown at the rear of the body. Figs. 2, 3, 4 and 5 show in detail the working out of the design and the arrangement of the interior seating. The dimensions are indicated.

The arched door, which is one of the distinctive features of this design, is placed about midway of the body and there is a single entrance on each side, in line across and directly facing; this entrance gives ample and free access to the rear and the small side seats, and the entrance to the front seat is made by tilting up the right half as illustrated by dotted lines on front view, Fig. 5. In Fig. 2 is shown the back of the seat dropped down preparatory to raising the seat cushion. The back of this seat is divided in the center and either half can be made to fold down, making possible for the driver to leave by first lowering the back of his seat and then stepping over the seat to the floor at the rear. The ventilator dome is carried sufficiently forward to give the maximum walking height as far as the front of this seat.

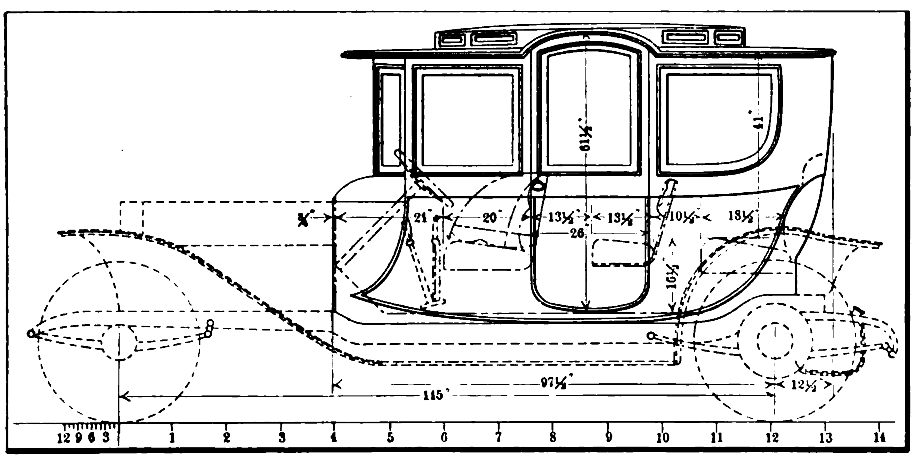

Fig. 2—Diagram showing the dimensions of single-compartment limousine body

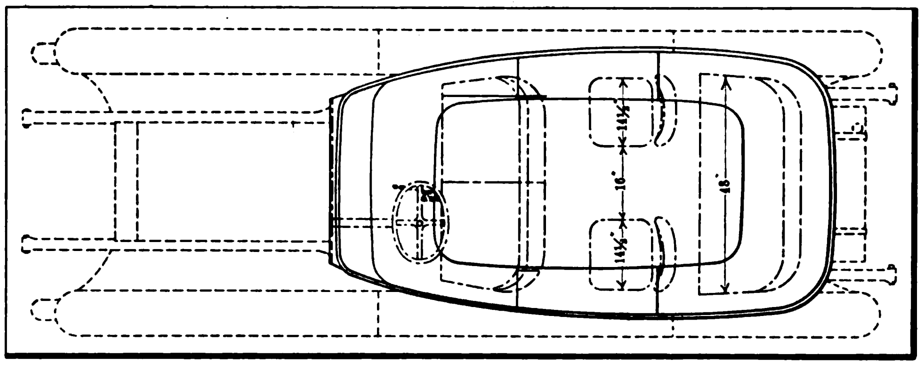

Fig. 3—Plan view showing the roomy arrangement of seats and location of steering wheel

The overall body dimensions of the design illustrated are no more than the average seven-passenger limousine, exclusive of the dome in the roof. This latter not only gives extra height inside and permits of a higher doorway, but the glass frames are made to open so that a perfect ventilation of the car is assured, without the disadvantage of a strong wind blowing onto the car occupants. For warmer weather, it is possible to entirely open up the car by dropping the glass frames in the doors and at the back and front of the doors on the sides, as well as open up the front or wind shield glass; in addition there are small screen ventilators in the dash at each side of the bonnet. The single-compartment body permits of the maximum room inside lengthwise, as the division is cut out or done away with and it also permits of a clear vision ahead for all the occupants of the car; and in the design illustrated the front corner windows are rounded slightly to better accommodate a view ahead for those seated at the rear.

Body designs, as here illustrated, are gotten up for a specific use and it is intended to be used during that part of the year when the weather is cold and disagreeable; every occupant of the car is comfortably housed and if it was desired the body could be heated from the exhaust. The trimming, the appointments and the general tone of the finish and the painting should be of the very best that money can purchase, for whereas bodies that are intended for Summer use are made to look light and attractive for the hot weather, such a design as here shown can be made to carry all the weight of luxurious fittings that the wish of the purchaser can desire.

Another feature that is becoming quite common among the owners who possess more than one car is, wherever it is practicable, to have the chassis duplicate. This has been brought about by the need of having any body fit the car that for the time is in commission, and as during the early Winter and late Spring season the bodies for both Summer and Winter use are liable to be wanted, the feature of having any body fit any chassis helps to facilitate the smoothness of the running of things.

Cylinders Require Reboring—The metal in the cylinder walls is too soft to stand continuous service. Designers desiring, in the first place, to have the weight efficiency as high as possible take advantage of the fact that white metal is dense, hard and strong. Gray iron, on the other hand, is soft and is likely to be of varying texture. White metal in a cylinder is induced by so regulating the charge that it will take on the property technically known as "chill." This "chill" is not to a great depth in good cylinder metal, so that in order to preserve the white metal surface the finish must be restricted. It will be remembered that all finished metal is machined off, and what is wanted in completed cylinders is just enough finish to permit of making a smooth bore without cutting through the white metal coating into the gray iron texture. In the primary design of the cylinder a reboring factor is always allowed if the bore of the motor is above 3 inches.

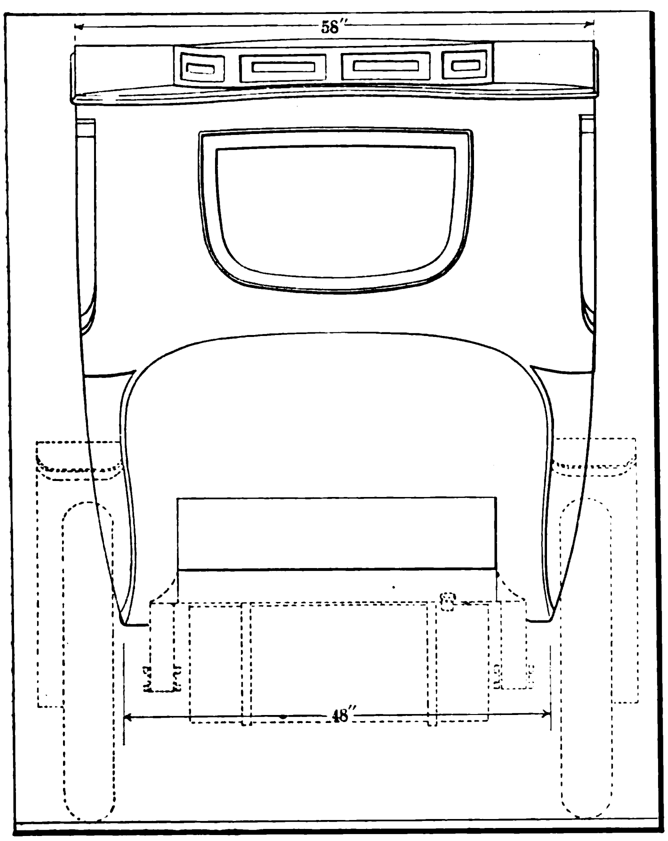

Fig. 4—Rear elevation of the new single-compartment limousine body, showing trunk

Fig. 2—Intake side of motor, showing the carbureter and double distributor magneto

Mercer Thirty-five in Detail

THE leader of the coming season's line of Mercer cars, which are manufactured in Trenton, N. J., will be the 35-horsepower model. The motor of this model is shown in Figs. 1 and 2. Fig. 2 shows the intake side of the motor, which is of the four-cylinder, four-cycle type, with cylinders cast in pairs. The valves are located on either side of the motor, the cylinders being cast with T-heads. The diameter of the intake valve is 2 inches, and the seat is given an angle of 45 degrees. The valves have a lift of 7-16 inch, and the valve setting can be seen by referring to Fig. 7. The motor has a bore of 4 3-8 inches and a stroke of 5 inches.

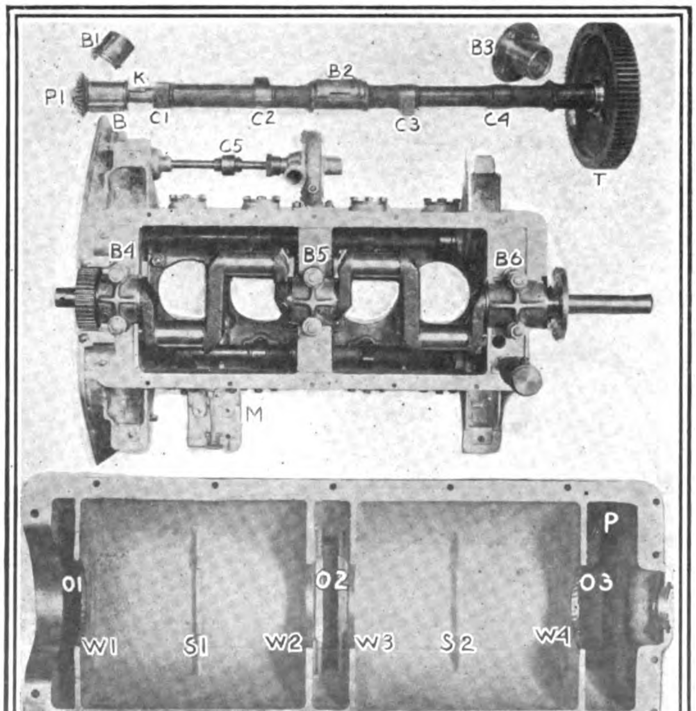

Fig. 3—Showing the base chamber and its components

The ignition is furnished to two independent sets of spark plugs from a magneto with a double distributor, whereby two sparks take place simultaneously in the firing cylinder. Fig. 2 shows the magneto in position, resting upon a ledge L which is attached to the upper half of the base chamber by three bolts.

The carbureter is of the float-feed, constant-level type, bolted to a flange of a bifurcated intake manifold; the air adjustment has been simplified so as to give a separate adjustment for high and low speeds. Fig. 2 also shows the two arms S1 and S2, which rest on and are bolted to a sub-frame of the main chassis. Oil is poured into the base chamber through the large vent pipe F1 and the level of the oil in the base chamber can be read upon the gauge G.

The water cooling is taken care of by means of a cellular radiator placed in front of the motor supported on ball trunnions, whence the water is delivered to the centrifugal pump P and thence to the base of the exhaust valve chambers. In order to render the dismantling of the pump as easy as possible, an Oldham coupling C is interposed between the shaft attached to the half-time gears and the pump shaft. An aluminum pulley P2 is attached by means of a taper pin to the pump-driving shaft and the fan F is driven by a flat belt B through the pulley P1.

The plates P3 and P4 carry the lever arms which are interposed between the cams and the valve pushrods. Referring to Fig. 14, the internal arrangements to operate the valves may be seen. The arms of the plate P1 carry the pivot pin A1 upon which the arm A2 reciprocates. The lower part of the slipper

S3 rides the cam, and the part S4 contacts with the pushrod R1. This is fitted at its upper extremity with a means of adjusting the lift of the valves, and in order to maintain the rod R1 stationary for this operation, flats are cut upon it at F. The nuts N1 and N2 form the adjustment.

Fig. 6 shows the method employed in securing the connecting rod to the hollow wrist pin. The connecting rod is made in the shape of an H instead of the conventional I-section, as may be seen from Fig. 14, which also shows the piston P, which is fitted with four concentric rings, all placed at the upper extremity. The lower part of the piston has a clearance between it and the cylinder of 0.008 of an inch, while the part situated above the top ring is given a clearance of 0.015 of an inch.

The crankshaft is carried on three main bearings, B4, B5 and B6, shown in Fig. 3, the lower caps of the bearings being held in position by 12-inch bolts which pass through the upper half of the base chamber. The timing gear T attached to the camshaft has a 1 1-4-inch face, the teeth being cut with a shaper. The camshaft is stamped integral with the cams C1, C2, C3, C4 from 7 per cent. carbon steel, which is annealed and hardened, the cams being ground to size. It runs on three main bearings B1, B2, B3 and the rear extremity is fitted with a key K which engages the collar carrying the pinion P1. The bearings B1 and B2 are split and lined with anti-friction metal.

The oiling system of the Mercer car has been carefully thought out and has been found to be most efficacious. In short, it is a combination of pump-feed and splash. Fig. 3 shows the lower half of the base-chamber, in which there are two compartments subdivided by the separators S1 and S2, forming troughs into which the lower half of the connecting rods dip. The oil that is carried in the sump shown at O1, O2 and O3, extending the whole length of the base-chamber, is taken by a pump and delivered to the three main bearings

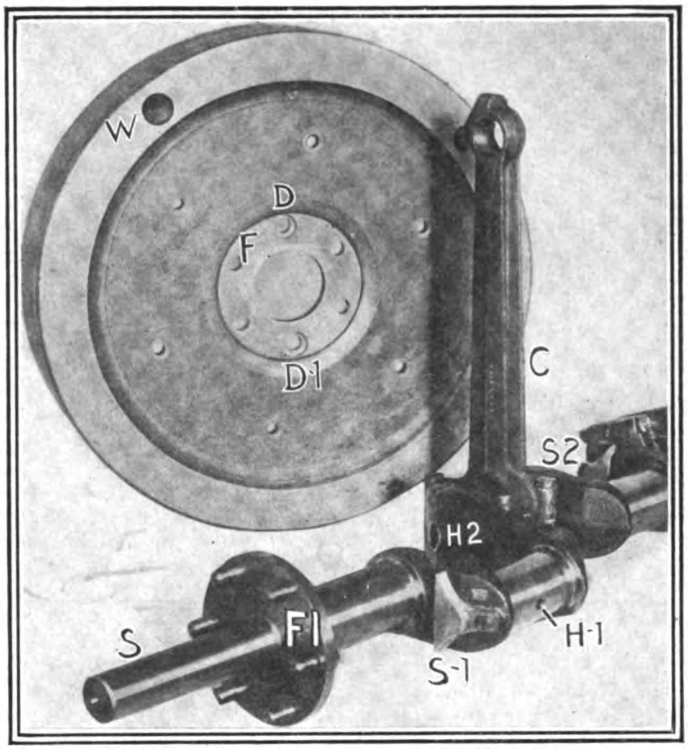

Fig. 5—Showing part of the crankshaft, together with oil cups and flywheel

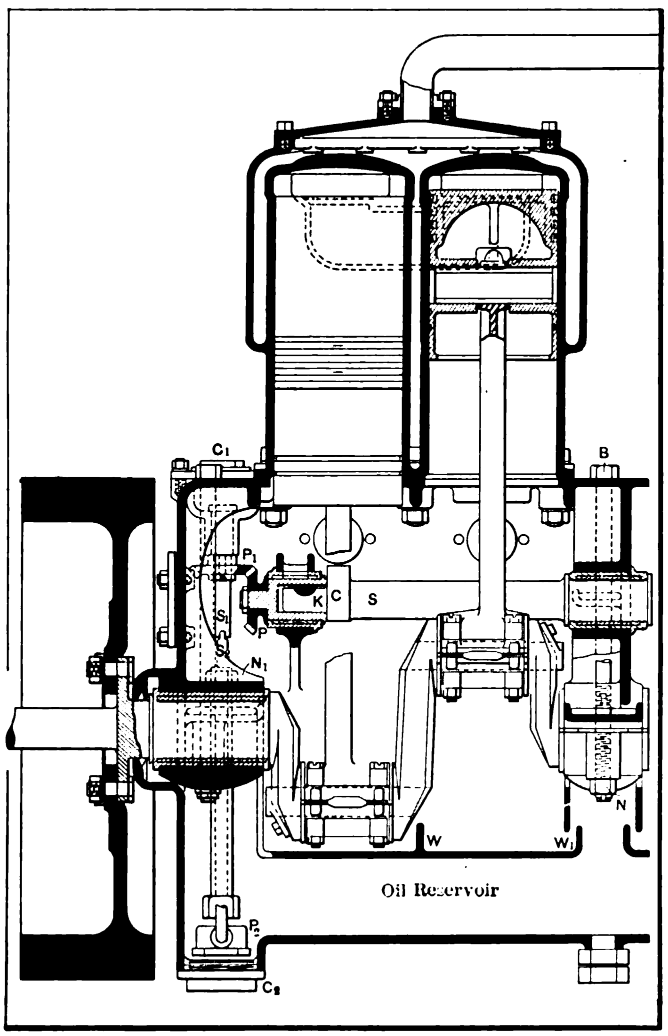

Fig. 4—Section of two rear cylinders, showing cam and crankshafts

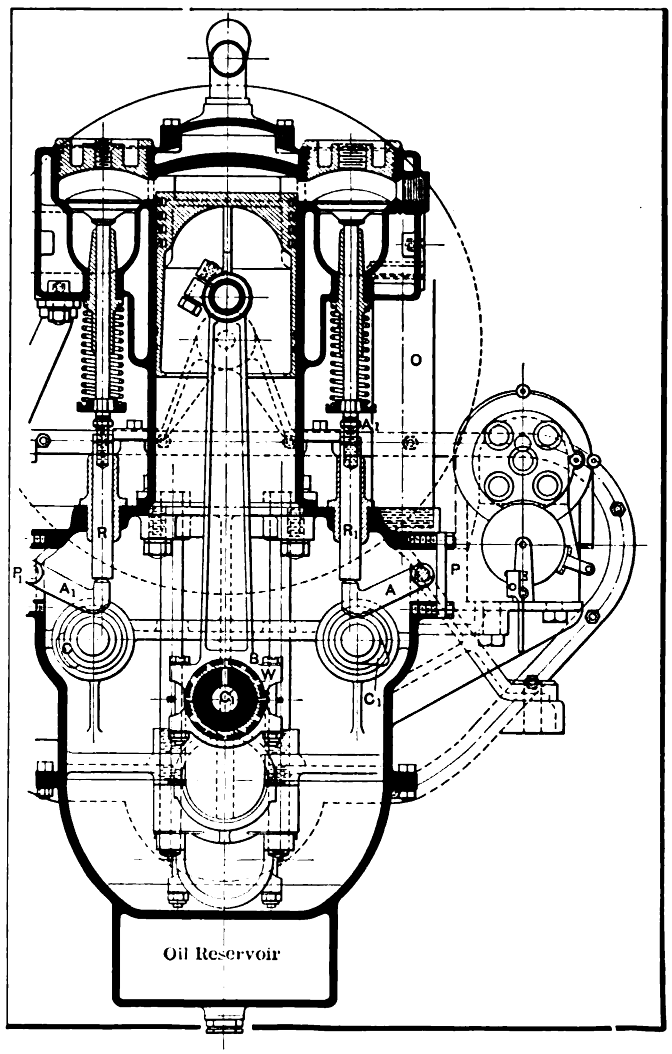

Fig. 6—Transverse section of the third cylinder of the motor

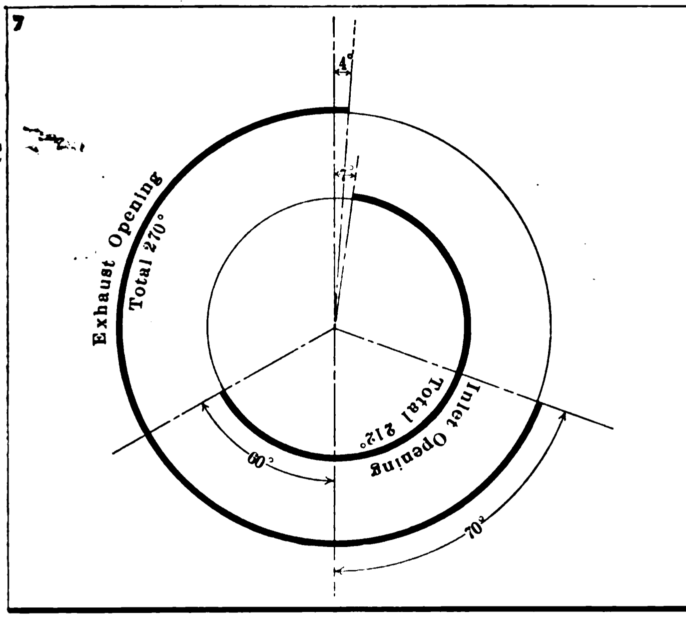

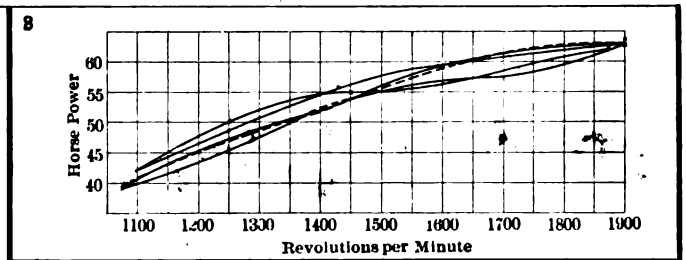

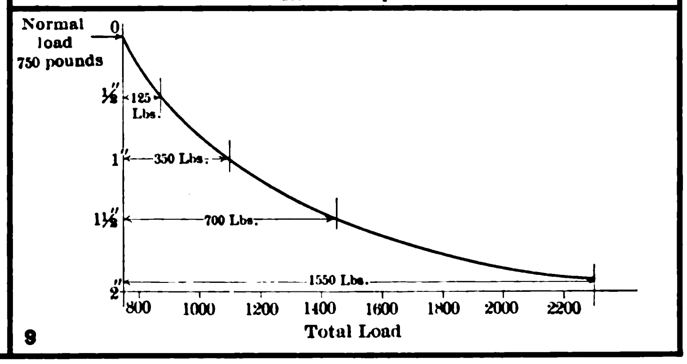

Fig. 7—Timing diagram of the Mercer motor, showing valve openings. Fig. 8—Horsepower curves of five Mercer motors taken indiscriminately. Fig. 9—Chart showing deflection of the rear springs of the Mercer "35"

of the motor. As the crankpins are drilled hollow, as shown at H2 in Fig. 5, the oil that is delivered to the main bearings is thrown out of the extremities of the bearings by centrifugal force into the cups S1 and S2. The oil then passes through the hollow crankshaft out into the big-end connecting rod bearings by the hole H1. The shims that are interposed between the two halves of the big-end bearings are wide enough to allow of sufficient gap between the upper and lower caps. The connecting rods strike into the oil in the troughs beneath them, thereby lubricating the cylinders, pistons and wristpins, as well as the camshaft bearings. As soon as the oil in these troughs reaches a certain level it overflows into the sump.

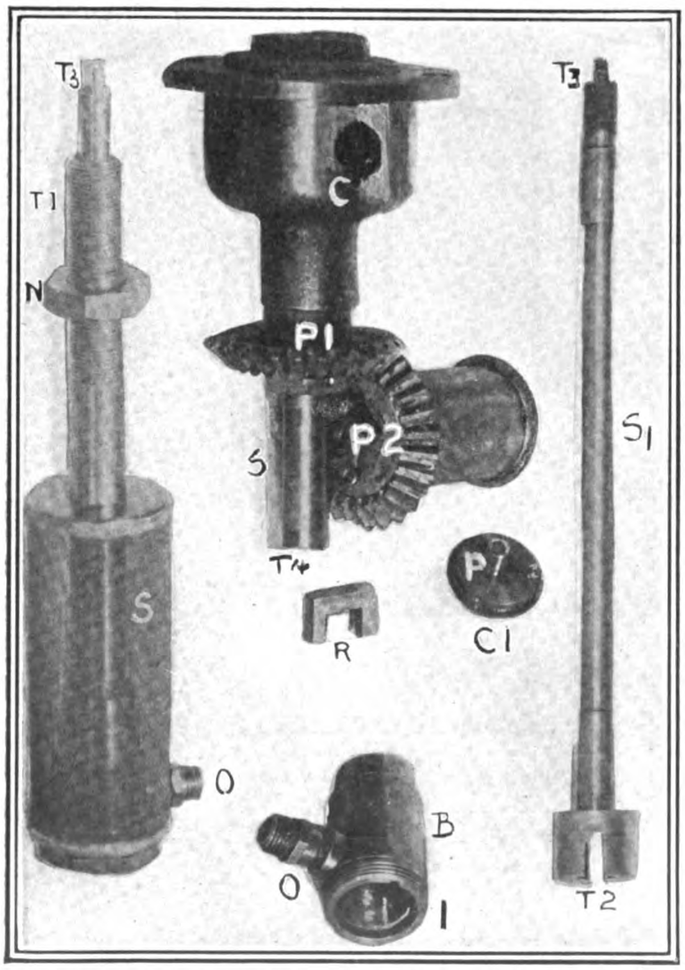

Fig. 10—Complete and detail assembly of the oil pump

The details of the pump may be seen by referring to Fig. 10. The cap C is bolted into the upper half of the base-chamber and carries the shaft to which the bevel pinion P1 is attached. This meshes with a pinion P2, which is attached to the exhaust camshaft in the manner shown in Fig. 3. The shaft S has a slot cut in it in order to accommodate the tongue T3, which is integral with the shaft S1. The lower extremity of the shaft also has a slot cut in it, T2, in which the U-piece R slides. The pin P on the cap C1, placed slightly eccentric thereto, is placed in the hollow of the U-piece R, and as the shaft S1 rotates inside of the body B1 the part R carries the oil that enters at I and forces it out of the exit O. The general assembly of the pump is shown at the left, a gauze screen S encircling the base of the pump, thereby filtering the oil and preventing impurities from being returned into the circulation.

An auxiliary oil tank is provided and oil is delivered to the base-chamber by means of a hand pump when required. On the dash is a sight-feed through which the oil from the pump passes to the bearings. This is of such construction that the flow may readily be seen.

A new design of gearset is being incorporated in next season's models, in which the clutch and gears are housed in the same aluminum casting, located amidships and bolted to the extension of the subframe that carries the motor. The clutch is of the multiple-disc type and the service brake, which is located at the rear of the transmission, has a diameter of 10 inches and a a width of 3 inches. The friction surfaces are cast-iron shoes

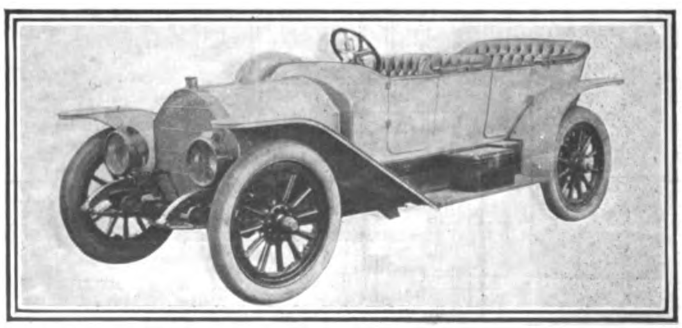

Fig. 11—General appearance of the Mercer fore-door torpedo

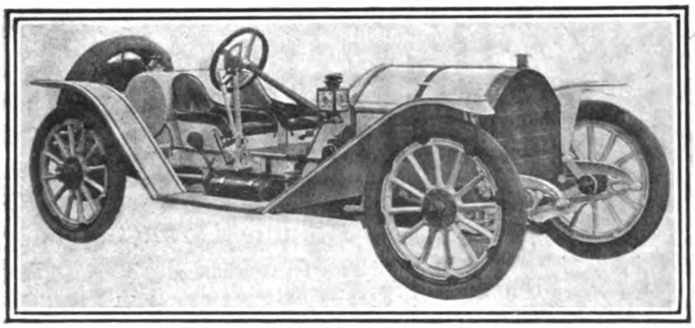

Fig. 12—Mercer raceabout, showing method of carrying gasoline tank and tires

to the steel drum. Three speeds forward and one reverse are furnished on the raceabout and runabout while four speeds forward and one reverse are fitted in the case of the four or five-passenger cars.

The general scheme of the live rear axle may be seen by referring to Fig. 12. The housing is formed by two pressed steel members welded together and the tubes T, which carry the weight of the load, are swedged into the main body and afterward riveted as an extra security. The shaft S, which is connected to the propeller shaft by means of a universal joint, is carried on two annular ball bearings and the end thrust is taken care of by the thrust bearings T2 and T3. The housing H1, to which the crown wheel is bolted, is carried on annular ball bearings, side-thrust bearings being employed as well. A torque member is attached at T1, which is part of the front end of the casing.

The rear cover of the differential casing is removable and after the live rear axle shafts have been sufficiently withdrawn it is possible to remove the differential unit. The wheel hubs are fitted with two annular ball bearings which slip over the tube T and are locked in position by means of the ring R, and the dogs at the ends of the shafts fit into corresponding slots in the hub. The driving member is attached to the ends of the shafts upon four keyways cut therein, but the ends that fit into the differential body are squared. The interior of the emergency brake may also be seen in Fig. 12. The drum is 14 inches in diameter, 2 inches wide, the shoes being faced with asbestos fabric liners.

The suspension of the raceabout and runabout is taken of

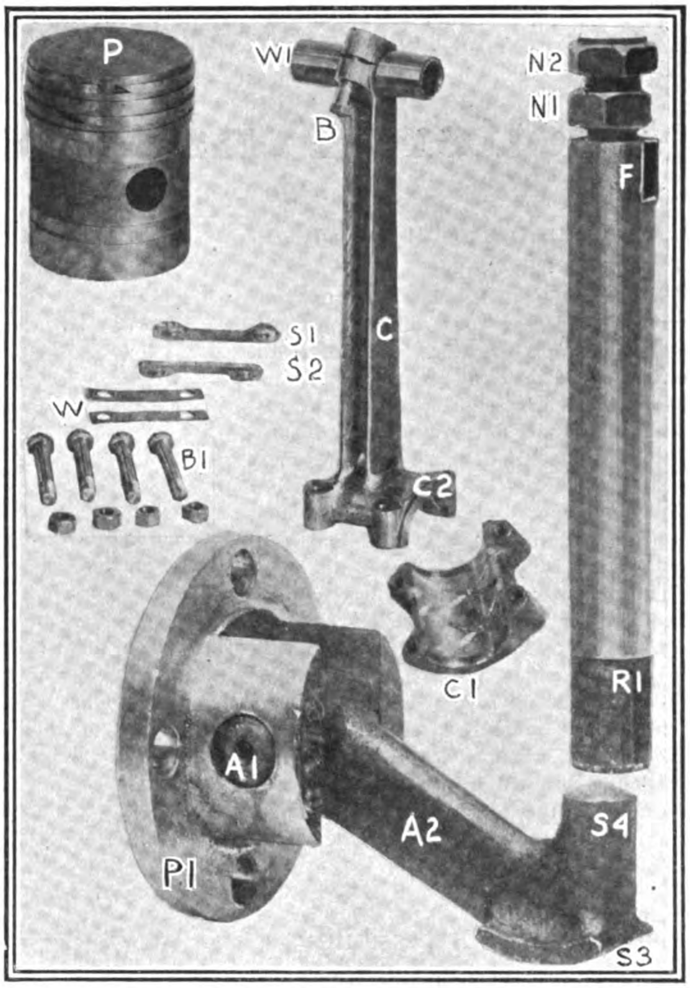

Fig. 14—Showing the piston-connecting rod assembly, also valve operating parts

semi-elliptic springs all around, but the touring cars have three-quarter-elliptic springs at the rear. Fig. 9 shows the degrees of deflection of the springs for various loads, and it will be seen that as the weight increases the deflection decreases.

Letters Answered and Discussed

The Editor invites subscribers to communicate their automobile troubles and personal experiences, stating them clearly on one side of the paper. If the nature of the case permits, send a sketch, even if it be rough, in order to assist to a clearer understanding. Each communication will receive attention in the order of its receipt, if the writer's signature and address accompany it as an evidence of good faith. If the writer objects to the publication of his name, he may add a nom de plume.

Measuring Compression

EDITOR THE AUTOMOBILE:

[2,832]—As a subscriber to your valued paper I am taking the liberty of asking you a question in regard to the measuring of the compression of a motor. I have tried in vain to estimate it by various means and have not obtained satisfactory results. You would be doing me a great favor if you would let me know if there is any accurate means of measurement and, if there is, how it is done.

Oakdale, Cal. JAS. CARLTON.

The compression may be accurately measured by attaching a gauge as shown in Fig. 1. The spark plug is removed and the gauge screwed in position. The engine is then turned up slowly against compression and the pressure noted. Cold compression as determined in this manner will be slightly different from the running compression, as the pressure in the cylinder will not be atmospheric when the engine is operating with fuel.

Believes in Accessibility

Editor THE AUTOMOBILE:

[2,833]—I have just been reading your editorial on the subject of accessibility and an accessibility contest, and I heartily agree with everything you have said. As I understand, and believe, automobiles are and must be for the people and general use, and therefore, unless they are to be run and thrown away at the end of each year (and such a condition of affairs is quite impossible), every owner must expect to overhaul his car about once a year.

The question then is, Are the wearing parts so put together that they can be replaced as conveniently as possible? If not, then unnecessary expense and loss of time must be the part of the automobilist.

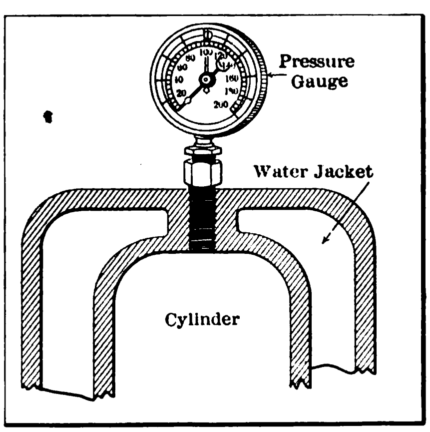

Fig. 1—Manner of inserting the pressure gauge in spark-plug hole to measure compression

Besides this there are many adjustments which must, for one cause or another, be made on the road.

I also agree with you regarding designing engineers. If a yearly contest was had in which they, personally, were to drive, adjust and repair over a route, say, one thousand miles long, it would show them the error of their ways in hundreds of cases, and might, if they were willing to accept the suggestions, result in making many cars what they should be, at little, if any, increase in cost.

It seems to the writer that the leading ideas for a designer should be suggested by the initials D. A. R., viz.: Durability, Accessibility, Reliability. I further believe that if the manufacturers of automobiles would send the users of their cars a set of questions regarding apparent faults and suggested improvements (as the publishers of several magazines have done), these answers (the result of natural and practical experience) would, if viewed in an intelligent and unbiased way, be of greater benefit to the manufacturer than any information he can get. Of course many answers and suggestions would be valueless for one good reason or another, but many would prove the way to great and lasting improvements. EXPERIENCE.

Kingston, N. Y.

The question of accessibility is now of timely interest and comments of this nature on the part of actual car users go a long way in showing the opinion prevailing and are therefore of exceptional interest.

Holding Down Cap

Editor THE AUTOMOBILE:

[2,834]—I have a screw cap on the gasoline tank of my car which is continually jarring loose. After running about 50 or 60 miles the cover will fall off owing to the vibration of the car. Is there any way that you know of to remedy this? I would greatly appreciate an answer at an early date in your letter columns.

ED. MURPHY.

Mt. Vernon, N. Y.

A handy way of stopping trouble of this nature is to take a brass clip of the shape shown in Fig. 2. Two bolts are passed through the tank as shown and held by means of nuts on the inside and the outside of the tank. The clip is then placed over the bolts and another nut (preferably winged) placed over the top in such a manner that the clip is held tightly to the cap.

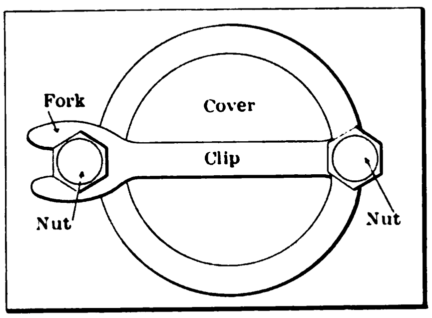

Fig. 2—Clip placed over screw cap to prevent it from falling off when subjected to vibration

Steering Knuckle

Editor THE AUTOMOBILE:

[2,835]—As a subscriber to your magazine I would like information on the following point: I recently saw a 1912 car of a prominent make on which the front axle, instead of being square with the floor on which the machine rested, was slightly inclined forward at the bottom so that the bottom bearing of the steering knuckle was very perceptibly in advance of the upper bearing. What is the reason for this? Will a car steer better if the knuckle is inclined that way than if it were perfectly plumb? R. O. BOGART.

Pluckamin, N. J.

A car will steer easiest when a line through the vertical center of the tires—that is, passing from the topmost point of the tire through the point of contact of tire and road—intersects at that point the line which is the continuation of the axis of the steering pivot. If these two lines intersect at some other point, or do not intersect at all, the steering will be harder. There is no gain in steering efficiency, so far as we are aware, in the suspension of which you speak.

Variety of Information

Editor THE AUTOMOBILE:

[2,836]—As a subscriber to your paper I would like to ask the following questions:

(1) What is a triple-seat valve, such as is used on the "Blitzen-Benz"?

(2) What is the bore, stroke and horsepower of the car which won the Grand Prize in 1910?

(3) I have heard that a carbureter will work very well with a car of one make, while with another it will perform very poorly. If this is so, kindly tell me the reason. SUBSCRIBER.

N. Y. City.

(1) A triple-seat valve is one in which the seat, instead of having one angle of seating, has three, which intersect each other at the valve seat.

(2) Bore, 155; stroke, 200 mm.; horsepower by American rating, 63; by makers' rating, 120.

(3) The different types of manifolds used on cars of different makes require a change of adjustment in the carbureter when it is shifted from one car to another. The carbureter itself should work just as well on one car as another provided it is of adequate size for either car. A large high-powered car will require a larger carbureter than that used on smaller motors.

No Scoop Necessary

Editor THE AUTOMOBILE:

[2,837]—My motor is lubricated by means of the splash system—that is, the connecting rods dip into the oil. There is no scoop on the bottom of the rod and I am not sure that it has not been left off by mistake, as a friend of mine has a machine which is lubricated in the same manner and he has a sort of copper spoon on the part of the rod which splashes into the oil. Is this fitting necessary? I would esteem a reply through your columns a great favor. CHAS. COFFEY.

Tarrytown, N. Y.

The scoop is not necessary, as there are several cars using the splash system which are without it. There is generally a hole in the bottom of the connecting rod in which the oil is caught up and thrown over the cylinder when the scoop is not fitted.

Oil Leaks from Crankcase

Editor THE AUTOMOBILE:

[2,838]—My car has the oil reservoir in the base casting, and since there seems to be a space between the flanges of the two parts of the crankcase casting the oil leaks through and runs down the side of the base chamber. Would you kindly tell me how to stop the waste of oil? I do not mind the small amount of oil wasted so much as the dirty appearance of the motor on account of the leakage. E. H. S.

Clarkesville, Tenn.

Take out the bolts which hold the upper and lower parts of the crankcase together and with a V-chisel cut a groove along the flange to take the packing, as illustrated in Fig. 4.

The bolts are tightened up after the packing, consisting of lead wire, has been put in place. When the bolts are tightened the lead will be squeezed into the groove and effectually stop any leakage.

Wedging Up Car

Editor THE AUTOMOBILE:

[2,839]—I have a very small car which I use for going about the country on business calls. Several times I have been obliged to stop on account of tire trouble and have been caught without a jack. The last time I tried to wedge the car off the ground, but found that the wedge would not slip along the rubber shoe. I have written you to find if there is any simple way of lifting the car without the aid of a jack. TROUBLED.

Vandalia, Ill.

It seems in a case of this nature the best advice is to carry a jack, as such a tool is usually very small and compact. If it becomes necessary on some occasion to wedge the car from the ground, it is useless to attempt to drive a wedge beneath one of the wheels. Two wedges and a plank should be used as is shown in Fig. 3. The plank is laid upon the ground with one of the wedges upon it. The car is then run or pushed upon the plank and rolled up the wedge for a short distance. Before the car can roll back the other wedge is laid upon the first, between that and the wheel.

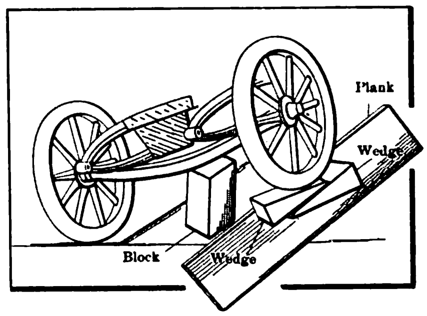

Fig. 3—Sketch showing the manner of placing wedges beneath wheels of automobile

The car will then take up the position shown in the illustration. The lower wedge may be driven in a little way to lift the wheel still higher. A block of wood is then inserted as shown and the wedges withdrawn to allow of the work being carried on. In lowering the car the wedges are replaced and hammered out gradually, thus allowing the car to be placed upon the ground without jar.

"Waterlogged" Float

Editor THE AUTOMOBILE:

[2,840]—For some time I was very much troubled by getting too rich a mixture at low speeds. This trouble kept getting worse until finally the motor could not be operated at all without getting a cloud of smoke and a large amount of carbon deposit on the cylinder walls. After attempting to remedy the trouble by making various adjustments on the carbureter and grinding the needle valve, which I strongly suspected to be the source of trouble when I first started to examine it, I have come to the conclusion that the cork float is soaked full of gasolene and has lost all its buoyancy.

How do you go about remedying a trouble of this nature? Is it necessary to buy a new float, or can I repair it at home? I have a garage which is very well fitted up with the various tools. AMATEUR REPAIRMAN.

Bath, Me.

In a case of this nature it is not necessary to buy a new float or even send the carbureter out to be repaired, as it may be very easily fixed at home. The float is removed and placed in an oven which is not too hot, and allowed to remain there until thoroughly dried out. It is then removed and given a coat of shellac and one of thin varnish.

Regarding Air Compressors

Editor THE AUTOMOBILE:

[2,841]—Would you kindly answer the following questions:

(1) What percentage of piston displacement will a 6-inch x 3-inch air compressor have if the compression space is ten cubic inches and the machine runs at 500, 1,000, 1,500, 2,000 and 3,000 revolutions per minute?

(2) What percentage of piston displacement with a 3-inch x 3-inch compressor having a port 3-8 inch x 4 1-2 inches opened by the piston at the bottom of the stroke, the air being drawn in through a 1 1-2-inch pipe 18 inches long, running at the same speeds as the above? W. M. BAUMHECKLE.

Cincinnati, O.

(1) The compression space will be 23.6 per cent. of the piston displacement. The piston speed does not affect this quantity.

(2) In order to determine the percentage of the compression space the volume of the same must be known, or, in designing a compressor, the desired compression must be ascertained.

It is difficult to calculate the volume of the compression space in some instances owing to the pockets and irregular valve openings.

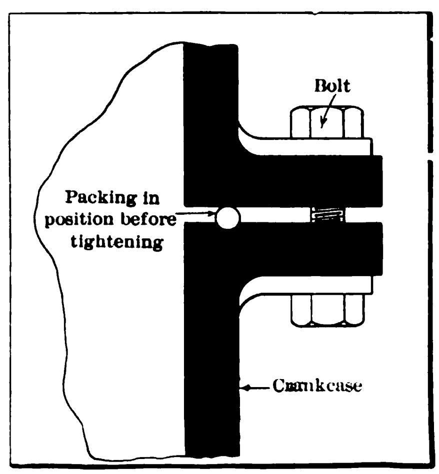

Fig. 4—How packing is placed to prevent leakage of oil from the crankcase

My 1912 Automobile

A Conception of What the Ideal Car Should Be

EDITOR THE AUTOMOBILE:

My conception of an ideal automobile is as follows: Price $2,500, fully equipped with top, glass front, two extra tires on demountable rims, either Dorian or Firestone Q. D., and with some kind of power pump for blowing up the tires.

The wheelbase should be 114 inches, with 56 inches tread and the car should comfortably seat five. The wheels should be 36 inches and the tires 4½ inches. Bearings should be roller for the wheels, babbitt for the engine and ball bearings in the transmission.

The transmission should give four forward speeds and reverse. The gear ratios should be approximately 12 to 1 on low and reverse; 7 to 1 on second; 4 to 1 on third and 3 to 1 on high. Direct gear should be on the third speed. This gearing, although very low for the third speed, would enable one to handle the car easily at slow speeds in the city, over the majority of roads and over hills without gear changing.

Steering should be by irreversible worm and sector gear.

Motor should be 4½ bore by 6-inch stroke, 4 cylinders T-shaped, cast separately, with 2¾-inch poppet valves, with lifts fixed so as to be adjustable.

Radiator should be on dash, with thermo-syphon system. This protects the radiator from strains and allows good water circulation without a pump. Radiator can be placed higher without interfering with view of driver. Fan should be bolted on flywheel edge. Hood should be of sloping type and it should be made practically dust-tight when closed.

The crankcase bottom should be removable without disturbing the crankshaft and all engine bearings should be then easily adjusted. The case should be tight so no dust could get to the engine, thereby doing away with usually inaccessible dust-pans.

Brakes should all be contracting, emergency on wide drums on rear wheels and foot brake on a very wide drum on the propeller shaft, all to be designed to adjust readily without tools.

Clutch should be multiple disc running in oil; about 60 plates should be used.

Ignition by magneto arranged so that it also charges a storage battery which furnishes current for lights and for auxiliary system.

Carbureter should be best actuated by throttle on wheel and foot control also, while the needle valve or the auxiliary air valve should be adjustable from the driver's seat.

Weight of car would probably be about 3,000 lbs. Road clearance ought to be about one foot.

Springs ought to be long and limber, with straps and rubber bumpers to prevent spring breakage.

Lubrication should be by splash from oil trough, oil reservoir to be in crankcase base. Oil should circulate through two sight feeds on dash and should be by two pumps, so if one became disabled the car would still be properly lubricated.

The price of a car such as above described might be brought down to about $2,200 and would give one an all-around car capable of going anywhere and easily handled in congested traffic.

A self-starting device similar to the one used by cars now on the market would be appreciated by the majority of people using machines. MARTIN J. D. ALBERTSON.

Glen Head, N. Y.

Harking Back a Decade

IN the issue of *The Motor Review*, September 19, 1901, the following items of interest to motordom appeared:

Secretary S. M. Butler, of the Automobile Club of America, has issued an order from the Board of Governors of the organization abandoning the scheduled Erie-Buffalo road race, the week of sports and the one-mile record race, all on account of the assassination of President McKinley.

Announcement is made that among the chauffeurs entered for a race meeting scheduled for October 10 at Providence, R. I., are the following: W. K. Vanderbilt, Jr., Foxhall Keene and Henri Fournier. Cups were offered for electric, steam and gasoline automobiles.

A big automobile show, to be held at the Coliseum, Chicago, under the auspices of the Chicago Automobile Club, has been given dates from March 1 to 8, 1902. The big West is thirsty for automobiles.

The projected automobile show at the Wisconsin Fair failed to materialize. The excuse is made that horses are an older institution than automobiles and consequently more popular.

The great Buffalo Endurance run, which started from New York with 79 entries, and was called off at Rochester after the shooting of President McKinley, was a great success. It was pointed out that 41 vehicles reached Rochester; thus only 38 fell out en route. The daily mileage was less than 80 and repairs and replacements within controls were allowed. Secretary Butler followed the column from place to place by train so as to insure reaching the night controls.—*Editorial.*

"A foot-pound saved in transmission is a foot-pound earned at the motor. 'Just as good' and 'practically as efficient' are but excuses for the weakness of making things good enough, rather than as good as possible."—*Technical filler.*

Among those who drove cars in the Buffalo run were the following: Elmer Apperson, David Ferguson, R. H. White, Herbert H. Lytle, J. W. Packard, Percy Owen, S. D. Waldron, A. L. McMurtry, John Jacob Astor, A. L. Riker and C. W. Wridgway.

The floral parade at Cleveland proved to be an unqualified success. George S. Waite won first prize for the most artistic decoration. His car was covered with flowers, carnations on the wheels and gladiolas and carnations in the body. Six white pigeons ornamented the front of the car while the rear was a blaze of red, white and blue flowers.

An effort has been made by the Board of Trade of Middletown, Conn., to locate the Fisher Horseless Vehicle Company in that city. The company has been employing 300 men at Hoboken, N. J.

John Towns, of Hamilton, Ohio, has purchased an 8-seated automobile bus from the Haynes-Apperson Co., Kokomo, Ind.

The Century Motor Vehicle Company has shipped a two-seated surrey to Germany.

Digest of Leading Engineering Papers

MATERIALS for light-weight construction fall into two groups, those of extraordinary strength, particularly the chrome-nickel and the non-corrosive high-nickel alloy steels, and those of low specific gravity with the strength as high as obtainable. Where construction forms run to mass and rigidity, without severe alternating or local strains, those metals which are both lighter and stronger than aluminum are gaining a place for themselves. Electron, made by the Griesheim-Electron Chemical Works, has a specific gravity of 1.8 and a tensile strength up to 3,500 kg. per square centimeter. It is not yet patented in Germany, but the American patent, 965,485, July 26, 1910, gives the alloy as 80 to 99.5 per cent. magnesium and 0.5 to 20 per cent. aluminum and other metals. The principal method used for removing injurious salts from this alloy consists, according to other Griesheim patents, in melting the alloy together with an alkaline chlorid, or mixture of such, whose fusion point lies considerably higher than that of the pure alloy. In the cooling the chlorid thus congeals first, and the molten alloy can be drawn off. It is kept molten for some time, preferably isolated from the atmosphere, or a neutral gas, such as hydrogen, is injected in the molten mass, whereby the last remnant of the chlorid is evaporated. To avoid porosity in castings of aluminum-magnesium alloys a similar method is used, under German patent 228,962 (Class 31, c), October 1, 1909. It was found that the molten metal at about 700 deg. C. takes up hydrogen and does not throw it off till just before congealing. The hydrogen comes either from the hygroscopic salts referred to or from the water vapors of the fuel gases, the water vapor being split by the molten magnesium, making $Mg + H_2O$ into $MgO + H_2$. To remove the gas completely, the metal is kept for some time at the temperature at which the gas is thrown out, which is only a few degrees above the melting point of magnesium, and this may be done while the metal is in the crucible or after it is in the mold. The gas escapes in bubbles, leaving a perfectly dense alloy.

The French patent, No. 407,814, with supplementary patent No. 11,905, gives the method of Walter Ruebel for producing a magnesium alloy. Zinc or copper and zinc or copper and aluminum are the admixtures used for binding the magnesium and obviating the many chemical reactions to which it is subject in its pure form. An alloy of 96 per cent. magnesium and 4 per cent. zinc has a tensile strength of 1,500 to 2,000 kg. per square centimeter, but rolled the same alloy reaches 2,500 to 3,500 kg. tensile strength and an elongation of 8 to 12 per cent. The zinc may be increased to 10 per cent. without reducing these figures, or 6 per cent. copper and 4 per cent. zinc may be used, or 9 per cent. copper and 1 per cent. of aluminum. The magnesium, however, must not fall below 90 per cent. or exceed 96 per cent. The production takes place in a wrought iron crucible, well covered, and in an ordinary coal fire. The zinc is added as soon as the magnesium melts and is absorbed at once. If copper pieces are added, they also melt at once despite the much higher fusion point of copper.

The oxidation in pouring is slight and the casting shows a perfectly smooth surface. It can be forged and rolled and does not tarnish in air or water. It can be machined like brass or bronze.

A similar alloy, made by Basse & Selve, in Altona, Germany, with a specific gravity of 2 when cast gives a tensile strength of 1,200 to 1,500 kg., but when drawn has a density of only 1.772 to 1.780, but a strength of 2,700 to 3,000 kg. A British-made alloy, known as cork-metal, is composed of magnesium with only 0.5 per cent. zinc, and its specific gravity is 1.762. Very recently the French firm, Esnault-Pelterie, of Billancourt, has obtained German patent No. 230,995 for an alloy composed of 80 to 85 per cent. aluminum, 5 to 10 per cent. of silver or another precious metal and 5 to 15 per cent. of a metal belonging to the iron group, such as cobalt, chromium, nickel or manganese. The silver has the effect of preventing the segregate crystallizing of the other metals, and a tough alloy is the result. In the production, the silver and the chosen metal of the iron group are first separately melted, then mixed in the desired proportion, and the mixture is then added to the molten aluminum.

The Ferro-Nickel company of Paris holds German patent No. 231,060 on a composition of 94 to 98 per cent. aluminum, 1.5 to 4 per cent. copper, 0.25 to 1.25 per cent. manganese and 0.25 to 1.25 per cent. silver. The total of the three admixtures must be between 2 and 6 per cent. These alloys can be drawn, stamped, forged and rolled, both cold and hot, and reach 2,800 kg. tensile strength per square centimeter with 1,400 elastic limit and 16 per cent. elongation in rolled and annealed strips 1 mm. thick. Rolled but not annealed, the tensile strength rises to 3,700 kg., but the elongation drops to 1 to 2 per cent.—Dr.-Ing. A. Sander in *Dinglers Polytechnisches Journal*, August 19.

QUALITY TEST FOR FINISHED STEEL AND METAL PARTS.—As the strength and other important qualities of an article made from steel depends to a considerable extent upon its shape and dimensions, if it has been subjected to heat treatment as well as in the case of castings, tensile tests applied to standard test pieces are not always available or practicable, and at all events they would not answer the question which is frequently the most important and which relates to the strength or hardness and resiliency in various portions of the same article. In this respect the method for determining hardness by indenting the article at various points of its surface by means of a steel ball of given diameter to which a given amount of pressure is applied and then measuring the indentations, has evident advantages. These the author has investigated through a series of experiments. He finds that the different portions of the same article usually show considerable variations under the ball-pressure test, but that the variations which should be ascribed to uncertainties in the testing method represent less than 10 per cent. of the variations which are actually existent in the tested article, provided proper scientific precautions are observed, and that the method therefore possesses a genuine value. It was found that the indentations are always accompanied by a conical rise or swelling of the adjacent metal and that the rapidity with which pressure is applied affects the result considerably, rendering it necessary to establish a uniform and slow action of the pressure levers for purposes of comparison. Other matters which were considered in the experiments related to the shape of the surface at the spot where pressure was applied and the direction of the "grain" of the metal, as determined by rolling or forging. No mention is made of the scleroscope, in the use of which the rebound of a steel ball allowed to drop from a certain height upon the article to be tested is measured in order to determine hardness and resiliency.—Capitaine Grard in *La Technique Moderne*, June and July.

THE WHIP AS AN ACCESSORY—In Germany the whip is becoming an accessory for automobile tourists, according to *Allgemeine Automobile Zeitung*. It has been found that cows, though they refuse to get out of the road in front of an automobile until bumped into, respond at once to the persuasion of a whip, and an enterprising firm has consequently placed an automobile whip in the market. It is of such dimensions that it can conveniently be put away under the seat until there is need for its services.

Little Bits of Motor Wisdom

Pertinent Pointers for Repairman and Driver

THE FACE SPANNER—It very often happens that a screw cover is placed in such a position that it is impossible to have a projecting nut on the outside of the cap. In this case the difficulty is generally surmounted by having a face plate cover in which there are two holes to take corresponding projections on the face spanner. The face spanner and the cover plate are illustrated in Fig. 1. In making this type of cover a depth will have to be allowed that will permit of the insertion of

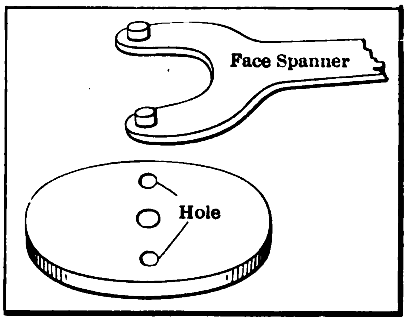

Fig. 1—Face spanner and face nut, showing holes in nut and projections on spanner

the wrench, for if the holes are too shallow it will not take much of a pull to tear them so that the cover will be worthless. Another method of making this type of spanner is to have it arranged so that it will fit around the cover plate, with a projection on the inner edge of the curve to fit into the corresponding hole in the disc.

A tool of this nature is generally sent with a piece of machinery in which there are nuts of this type, but in case it is ever necessary to turn them and the wrench is not accessible it is very easy to do it by hammering upon the slots. A piece of hard wood should be placed against the hole and the end can be hit with a hammer or mallet. The object of using the hard wood is that the use of metal would be injurious to the edge of the hole and hence the next time the wrench was called into service it would slip out.

THE INDUCTION COIL.— When the high-tension system of ignition is used with dry batteries an induction coil is used to transform the low-tension current of the batteries to the high-tension current which must be sent to the spark plug in order to jump the gap between the sparking points. The low-tension make-and-break ignition is effected by the electric arc described when two points break contact. The high-tension current, however, owing to its high pressure, will jump across a gap to complete its circuit.

The coil consists primarily of a soft iron core which is wound with coarse wire, this winding being placed around the tube which insulates the core. This winding is known as the primary winding and it is to this wire that the batteries are connected. The various turns of the primary or battery coil are insulated so that they are never in contact with each other.

After the primary coil has been wound about the core the secondary coil is placed about it. The secondary coil consists of very fine wire with a great number of turns, each insulated from the other in the same manner as the primary coil, great care being taken that there shall be no electrical connection between the primary and secondary windings. The greater the number of turns on the secondary coil, the greater the electromotive force produced by the coil, and naturally the higher the price of the coil.

The ends of the primary wire are led to the outer casing of the box in which the coil is always packed, one end being attached to a binding post, while the other is connected to the current interrupter, generally known as the vibrator or trembler, and then to a binding post. The ends of the secondary winding are attached to binding posts on the coil box, one fastening being made to the same binding post as that to which the end of the primary

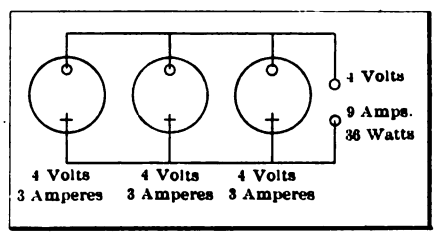

Fig. 2—Showing voltage and amperage at the terminals when connected in parallel

wire was attached, while the other is connected to a separate binding post. In coils not intended for ignition purposes the terminal of each winding has a separate binding post.

The battery is connected to the primary coil in such a way that the flow of the current is through the coil, trembler and back to the battery through a ground connection made to the engine frame. The trembler is a thin flat piece of metal which is held away from the core of the primary winding by means of a weak spring. At the other end of the flat trembler there is a fixed connection with the ground and a contact point with the primary winding, which is fixed as long as the trembler is in its normal position. When it is moved so that the contact points do not touch each other there is no electrical connection between the ground and the primary winding, or, in other words, the primary or battery circuit is broken. When the switch is closed a current passes from the battery through the primary coil, magnetizing the soft iron core. This magnetism draws the trembler to the core against the resistance of the weak spring, but in drawing the trembler towards the core the circuit is broken and the soft iron loses its magnetism, allowing the vibrator to return by means of the spring to its original position. The circuit is then closed again and the core remagnetized, whereupon the interruption of current again takes place and the trembler flies back into its original position, going through the same process repeatedly. These actions and reactions take place so rapidly that when the tension on the vibrator spring is properly adjusted a continuous humming sound caused by the vibration of the metal may be heard. The sound forms a means by which the practiced ear can distinguish the correct and incorrect trembler adjustments.

Each time the current through the primary winding is interrupted a counter-current of high voltage is induced in the secondary winding. The secondary winding is connected to the ground and to the spark plug, which is so constructed as to take the ground current and the direct wire without short-circuiting. The high-tension current thus induced leaps the gap between the points of the spark plug and produces a spark. Since the number of vibrations (and hence interruptions of the primary circuit) is so great, the high-tension current is likewise interrupted at the same speed and with the same frequency, so that instead of a single spark being sent across the gap in the sparkplug a continuous stream of fire is passing between these points, producing a hot and effective form of ignition.

In order that the sparks will not be continuously passing between the sparking points in the plug at the wrong time, a timer is inserted in the line, which switches the current to the cylinder at which it is needed at any given time. The timer is driven directly from the engine and may be advanced or retarded on its shaft from the driver's seat to correspond to the different positions of the throttle.

VOLTAGE AT BATTERY TERMINALS.—Up to a certain point, which is measured by the magnetic capacity of the soft iron core of the induction coil, the spark in a high-tension system will increase with the voltage sent through the primary coil. When the batteries are attached in serial form as shown in Fig. 3, where three batteries are connected for the purpose of illustration, the total voltage amounts to 12, while the amperage is 3. That is, where the batteries are connected in this manner, the effect is that of adding the voltage of each until the total at the terminals is equal to the sum of the voltage of all the batteries. In the case taken for illustration each battery had a capacity of 4 volts, so that at the terminals the electro-motive force was equal to 12 volts.

In connecting in series, the carbon point of each cell is connected to the zinc of the succeeding battery until the batteries are all joined together, leaving a carbon terminal free at one end of the chain and a zinc at the other. It is not true that when additional batteries are put on the circuit in connecting in this manner that the current is increased in the same proportion as the number of cells, but when used with the high external resistance given by an induction coil, the increase is very nearly proportional to the increase in the number of cells.

When connecting in parallel, as shown in Fig. 2, the current given off is just about equal in voltage to one battery if the external resistance of the circuit is high, while the amperage is equal to the sum of that of all the batteries. The watts in both cases are the same, 36, being, of course, the product of the voltage and amperage.

NECESSARY TO WATCH BEARINGS.—Whether the bearings be roller, ball or plain they are without doubt the most necessary parts of the car to watch. Every car owner or driver should know, after he has had his automobile for even a short time, the location of every bearing throughout the car. The symptoms of bearing trouble are always very evident, but the mere fact of their prominence suggests that they come when it is generally too late to avoid trouble.

When traveling along smoothly a grinding or grating noise of somewhat mysterious origin will sometimes make itself heard to the driver. The car will continue to run smoothly for a while until the grinding noise is followed by a breakdown which will nearly always be beyond the scope of roadside repairs. The general symptoms of bearing trouble are a grinding sound or in plain bearings a squeak, the latter generally being accompanied by heat. In other parts of the car there will be an excessive side play and a variation in the tightness of adjustment between one side of the bearing and the other. A plain bearing which has been allowed to become superheated will often seize.

The principal enemy of any bearing, if it has the proper care so far as lubrication is concerned, is grit. Grit will often be carried into a bearing by the lubricating oil, so that it is necessary in the first place to ascertain that the oil which is used for lubrication is of such quality that it is reasonably sure to be clean. To prevent the collection of grit, the bearings should be occasionally taken down and cleaned out. At these times the adjustment should be carefully examined and an excessive amount of play not allowed. Too tight an adjustment of any bearing is as serious a fault as too loose, as the oil will not be able to prevent the bearing from overheating on account of the increased friction. Ball bearings should be frequently examined for wear, since when the adjustment becomes loose the chances of the balls being fractured are greatly enhanced. A slight amount of wear can be taken up on the adjustment of the bearing, but where it is excessive the balls should be replaced at once.

Roller bearings give evidence of wear by a rattling noise which gradually increases as the wear becomes greater and the rollers are fractured. If taken down the rollers which are affected by the wear will be noticed to have groves which have been worn into them. Roller bearings, like ball bearings, are very seriously affected by grit, and it is very necessary that they be examined occasionally in order to ascertain if they are perfectly clean.

If a bearing runs hot while on the road and the driver is fortunate or skilful enough to detect it before seizur or serious damage occurs, the car should be stopped and allowed to stand while the bearing is cooling. The cooling should not be hurried by pouring cold water on the heated metal, as the result is very liable to be disastrous to either the shaft or bushing. A limited amount of oil may be poured on the warm bearing if it is desired to cool quickly, but even this practice is not as good as to allow the bearing to cool slowly.

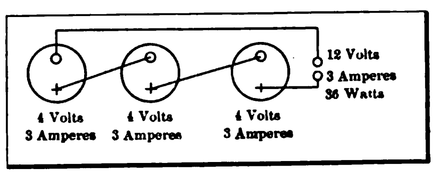

Fig. 3—Showing voltage and amperage when connecting batteries in series

If a ball bearing should fail through the breakage of one of the balls it is necessary to stop and carefully remove every piece of broken metal from the ball race, for if this is not done the other balls will be ground to pieces after having run for a very short distance. The ball should be replaced by one which is exactly the same size. If too large a ball is used the results would be much worse than if the car were run on a bearing which consisted of one ball less than the original number.

WHEN HEATING GLUE.—The purposes for which glue is used are so numerous that it is often called into service around the garage as well as in other work. It requires heating after it has stood for any length of time, so that it is often necessary to wait until it is sufficiently heated in an uncovered water pot, since the glue cannot well be placed directly upon the fire. There is a form of glue pot which is much used among wood workers which would be a handy adjunct to the outfit of any garage where repair jobs are done. It is illustrated in Fig. 4, and consists of two pots, an inner and an outer, which fit together.

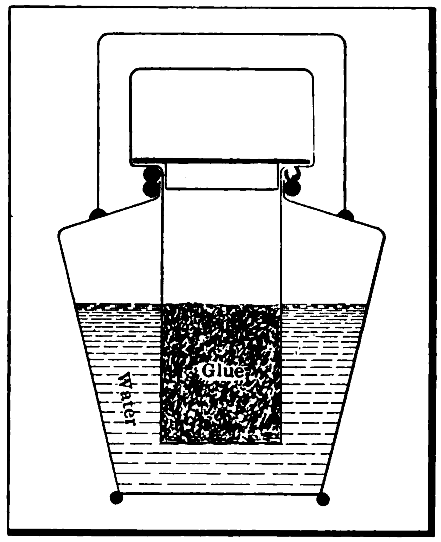

Fig. 4—Form of glue pot often used among wood workers. Adaptable to garage work

The outer pot contains water while the inner fits directly into it, being supported by the top as shown. Since the inner pot is suspended in this manner the water is free to circulate about it and when placed upon the stove all the heat will be concentrated upon the glue in the inner pot. The cover prevents the escape of vapor from either the water or the glue pot, thus doing away with the unpleasant odor which generally accompanies the process of heating glue. The glue will be kept warm for a longer period of time, as the heat will be contained within the closed vessel instead of being given off to the surrounding air.

There are two handles on the pot. The outer handle will lift the entire outfit in case it is desired to keep the glue surrounded by the hot water, while the inner handle is for carrying the glue receptacle alone.

CARE IN FITTING SPARK PLUGS—When screwing the spark plug into the cylinder care must be used so that the porcelain insulation on the outside is not cracked. An elusive misfire may frequently be traced to this cause. The current leaks from the grounding in the cylinder and creates an intermittent short circuit. There are several devices which have lately been placed upon the market for detecting just such a state of affairs.

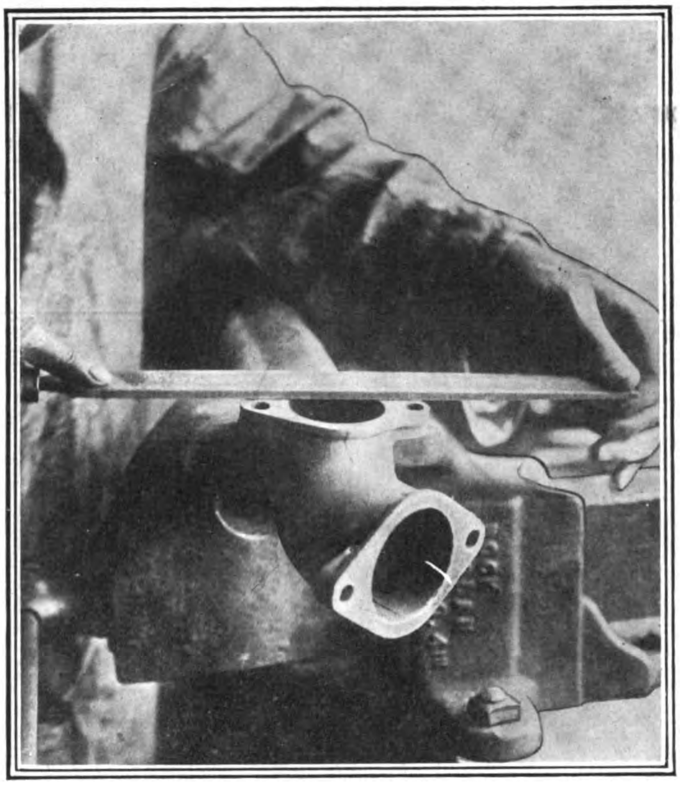

Fig. 1—Filing manifold flange to receive a new gasket properly, after the old one has been scraped off

Careful Inspection

Look for and Remedy Leaky

TO the automobilist who takes care of his own car the words "tuning up" express the very essence of careful inspection of the machine and the elimination of the slightest imperfection in any part of the running gear. It is a process which is something beyond the ordinary inspection which the car is given before being taken out for a run in the country, and expresses a greater refinement of every part of the mechanism than that given in the average overhauling. The elimination of noise goes hand-in-hand with the promotion of efficiency, and it may be said, in fact, that the elimination of all noise would mean the attainment of the highest degree of efficiency possible. Friction produces noise and heat which are both forms of energy and hence represent the dissipation of the power which might have been through better mechanical arrangement, added to the propelling force of the vehicle.

It is, of course, understood that it is impossible to prevent the loss of mechanical energy which takes place through the friction of joints and bearings any more than it is possible to eliminate giving away part of the power of the motor by throwing heat into the cooling water to keep the cylinder walls at a temperature at which they will work to the greatest advantage. All these heat losses and other losses are to a large extent necessary, but in the car which has been properly tuned up they have been reduced to a minimum. In the matter of bearings, for instance, an adjustment may be made which, while allowing a small amount of play, still holds the bearing properly to its work. Such an adjustment may be made in the universal joint, as shown in Fig. 2, where the act of making the adjustment is depicted. In this case the block B can be allowed a little play and the efficiency of the joint still be maintained with a slight gain in flexibility. The play given must be very slight—in fact, so slight that it can hardly be detected, but if the adjustment be correctly made, it will be found that the resistance to the free movement of the block in the fork will be practically nothing. Breakage of the universal joint, while not a common occurrence, will sometimes happen where the shaft has been considerably thrown out of alignment on account of some accidental derangement of the drive. Such a case is illustrated in Fig. 3, where B is the casing ring, F the collar, C the clip which has been bent back, and R the spindle about which the missing roller revolves.

Leaky manifolds are encountered at times and the hiss of the loose exhaust is unmistakable. In this case the joint is generally found to be defective owing to the gasket having been burnt or worn out. A very satisfactory repair may be quickly made by merely cutting a new gasket and fitting it in place of the old one. This is not the kind of repair, however, that is made in carefully tuning up the motor to secure the highest efficiency in all its parts, as very often at least a part of the old gasket will find its way into the manifold and cause trouble eventually. If the exhaust pipe is carefully removed and clamped in a vise, as shown in Fig. 1, and the file worked over the surface of the flange after the old packing has been carefully scraped away, a much more satisfactory job will be made and the man who performs the work will have classed himself with those whose automobiles far outlive the cars which receive nothing more than the average care. In filing the flange in the horizontal manner depicted in the illustration referred to above, a burr will be raised on the inner edge of the flange which should be removed. This is done by filing vertically, as shown in Fig. 4, where the operation of removing this burr is depicted.

Besides the matter of manifolds and bearings there are many others which should claim the attention of the automobilist if he entertains the idea of maintaining his car at the highest state of efficiency, either as a matter of economy or pride, or both. One of these points which require the attention of the motorist who aims at the attainment of the highest power possible from his engine and yet is very frequently overlooked is the muffler. A muffler is designed for the purpose of silencing the exhaust, which without it would be very noisy. To silence

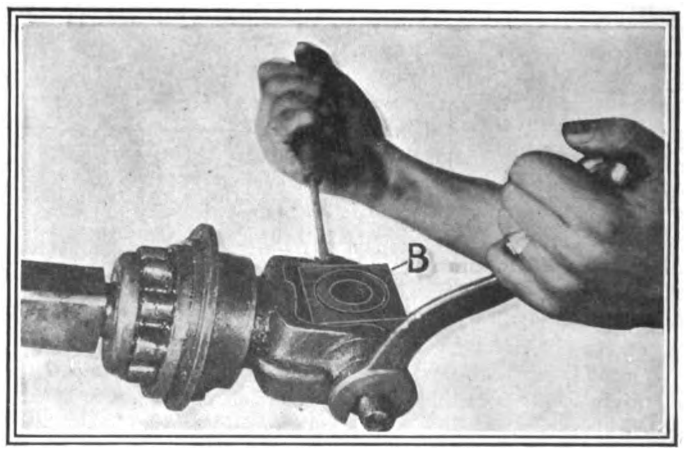

Fig. 2—Manner of adjusting for play in universal joint with a wrench and screw-driver

the exhaust a certain amount of power much be sacrificed by increasing the back-pressure against the exhaust of the motor. After a time, especially if the motor has been running with a superabundance of lubricating oil, the muffler becomes clogged with soot and dirt, thereby increasing the back-pressure against the exhaust. The loss of power occasioned by the resistance to the free exhaust is very large, and hence care should be taken to remove the muffler casing from time to time to remove the deposit.

A slipping clutch is an evil that should be corrected as soon

Will Pay the Owner

Joints, Slipping Clutches, Etc.

as it manifests itself, for each time that the clutch slips an additional glaze is given the leather if it is a leather-faced cone clutch, and the trouble which at first seemed very unimportant may result in disaster on a steep, slippery hill. The life of the clutch can be prolonged if care is used in driving the car and an occasional dressing with neat's foot oil is applied.

The needle valve on the carbureter will occasionally need grinding in the same manner as the valves in the cylinder head. If it is noticed that too much gasoline is fed to the motor at low speeds the trouble is often at this point. It is, of course, frequently due to the presence of a piece of foreign matter which has found its way from the gasoline tank into the carbureter, but occasionally it will be found that after having driven the car for a long time with the same carbureter the needle valve will require this adjustment. When the valve is ground the attachment of the float will have to be inspected and perhaps regulated in order that the gasoline level in the float chamber will correct; that is, about 1-32 of an inch below the spray nozzle.

Another feature which may be given attention in the final tuning up of the car is the distance between the points of each spark plug and whether they are choked with soot or are bright and clean. A considerable falling off in power will be the result of a dirty spark plug, and the same may be said to be true of one in which the gap is not great enough. When the gap is too wide the explosions will be irregular or the particular cylinder in which the defective plug is located will be "dead" entirely.

The constant vibration and jar of the car will loosen the battery and other terminal connections after the car has been

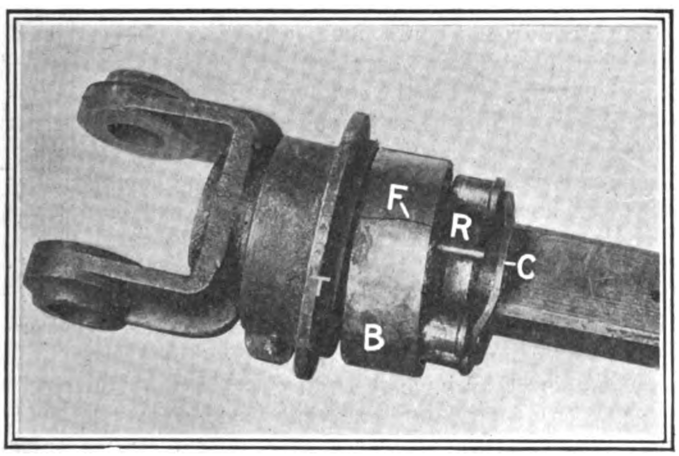

Fig. 3—A universal joint which has been broken by being knocked too far out of alignment

operated over rough and difficult roads. These should be examined from time to time in order to ascertain if they are tight as well as to determine whether any deterioration has resulted from contact with acids or other materials which would be apt to affect the wiring. If the contact points of all the wiring are first scraped and then rubbed with a piece of emery paper before the binding posts are screwed into position the contact will be much better than if the connection were carelessly made, and the spark will be hotter and hence more satisfactory. Badly-made connections form a resistance against the flow through the elec-

Fig. 4—Removing the burr after having filed the manifold flange to take the new gasket

tric circuit and hence cut down some of the electro-motive force that might have been used in producing a good spark. A very good plan that is sometimes used in careful wiring is to slip a piece of rubber tube over the wire and the terminal. This will tend not only to protect the wiring from galvanic action, but also to hold it in position in spite of vibration.

The maintenance of a clean radiator and circulating system is of prime importance. When the radiator is designed for a certain motor the area of cooling surface and the quantity of cooling water required for various engine speeds are determined. A factor of safety over the required area is allowed so that in case of an overload or other unforeseen condition the radiator will be able to adequately care for the motor. These calculations are all based on a clean radiator and not on one which has been fouled and clogged through neglect. A monthly cleansing will go far in creating a condition of high efficiency and economy in the motor.

Tire troubles are the bugaboo of the automobilist. The high price of rubber and the necessity of using the purest and highest grades in the manufacture of tires, have brought about this condition. If it were realized that the proper way to take care of a tire is not to place it on the car and then forget it until the much-dreaded blow-out occurs, methodical and frequent inspection of the outer casing would be the rule of every automobilist who desires to have the maximum pleasure from his car at the smallest monetary output. There are many very satisfactory vulcanizing outfits on the market which make it easy for the work to be carried out in a garage which is not overstocked with tools. A car cannot be said to be properly put in condition if it is allowed to go out with the tire casings cut. One of the greatest causes for the rapid deterioration of tires is the fact that water will work through the cuts and rot the fabric. This will eventually lead to a burst which could easily have been prevented with a little energy and foresight. In the points mentioned, as well as in all the other details which will present themselves at different times to the car owner and driver, a careful supervision will be rewarded by a prolongation of the life of the car and increased comfort in drivinig.

THE AUTOMOBILE

Track Racing Danger

THE accident that happened last Saturday at the track meet at Syracuse when eleven lives were taken is one that might happen at any track meet where the spectators are not kept in proper bounds. The outer and inner fences, which may be entirely safe for horse racing, are most inadequate when automobiles engage in speed contests, and wherever spectators are allowed to stand close behind such fences, whether on the stretches or on the curves, they place themselves in great danger, for should a tire go at such points there is a chance that the car may dash through the fence. The safety precautions that are adequate for horse racing are not to be even considered as possessing a shadow of what is required for automobiles. The only safety precaution that is adequate for racing cars is a low cement wall such as is used on the Indianapolis speedway; or low plank fences just high enough to catch the hubs of the racing cars and prevent them from leaving the track. Such fences are used on the motordrome in California, and similar precautions were taken on the Atlanta speedway and at the recent Elgin races in front of the repair pits extending along the grand stand.

Track race promoters and owners of horse tracks have been complaining all summer that the American Automobile Association has been placing undue, or unnecessary, restrictions on track races; as a matter of fact they have not been placing half enough restrictions upon them. A track owner imagines that because his track, with fences, paddock and spectator arrangements, is safe for horse racing, it is similarly so for automobile racing. This is as far from the real situation as can be imagined. Spectators must be protected no matter what the cost, and if the automobile sport-governing body does not make its promoters, to whom sanctions have been issued, furnish that protection, then the courts will step in and demand the protection or legislate against track events. What is needed most of all in track races is a safety wall along the outside and the inside of the track where spectators are bound to gather. If this costs too much money then the ground surrounding the track should be so fenced off that spectators cannot get within 75 feet of the side of the track—that is, the inner or the outer fence. This neutral zone would give the driver a chance to reduce the car speed and give spectators a chance for safety. Such fencing would not be a hardship because with all of the spectators that distance back from the track a better general view of the contest would be afforded. Quick action of this nature should be taken by the American Automobile Association, and the Manufacturers' Contest Association should be ready to back up the A. A. A. in such work. Human life must be protected; the spectator has to be looked after; the driver knows he is engaged in a dangerous occupation and takes his chances, but this does not apply to the spectator.

* * *

Practical Road Work

GETTING the different road commissioners of various States together for joint conferences and making an inspection of the roads in their respective States, as was done this week with the co-operation of the Touring Club of America, is a commendable enterprise. Good roads conventions are generally held in hotel parlors, or in the auditorium of a theater or music hall; but here is an example of where the meeting has been taken onto the highway, where the roads are on exhibition. It is the most practical, common-sense scheme that has been worked out along the good roads line and should be most productive of results. It is one thing to talk the construction and maintenance of good roads in a nice warm room at a convention, and it is another thing to get into a line of automobiles and go over the roads in rain and shine and see at close quarters just what are the conditions.

If there is any department of the automobile industry that needs the practical seed sown—and good roads must be considered such a department—it is this one. Many good roads conferences are based on road construction ideas of ten years ago under the horse régime. This is wrong. What the road commissioner has to do is to build a road for the automobile and study from present conditions what are the defects in existing highways. When the automobile road is finished the commissioner must see how it stands the traffic. He can best study this by travelling over the road in the automobile.

Other States would do well to imitate the example that some of the New England States have set. It is better for the commissioners of several States to get together and compare notes. The road chiefs of one State may imagine they have the entire world at their feet in the matter of road building, but when they meet with commissioners from other States they may find that there are other chapters to the good roads ritual. Unanimity is most essential in good roads work. The automobile is an interstate vehicle of travel; each automobile owner has more or less interest in the acts of the road builders in adjoining States. For this reason the interstate scheme of inspection is preferable to the State system. Continue the State system; where it has not been instituted, start it at once. But by no means end here; take the additional step of getting several States to unite. This will be of great assistance when it comes to the matter of mapping out and building as well as caring for interstate road systems.

Gossip of the Coming Shows

ARRANGEMENTS for both National automobile shows that will be held in New York in January, are progressing satisfactorily. While no definite official announcement has been made that the third show has been called off, nevertheless it will not be held. The reasons for this are twofold. In the first place the Columbus Buggy Company, Geneva Wagon Company, Seitz Automobile and Transfer Company, Maytag-Mason Motor Company, Lion Motor Sales Company, Alpena Motor Car Company, Roader Car Company, Vandewater and Company, Crawford Automobile Company, Warren Motor Car Company, James Cunningham and Son, McFarlan Motor Car Company and the Michigan Buggy Company, all of which were represented at the show held under the auspices of the A. M. C. M. A. E. last year at the Palace, have been reinstated to good standing in the N. A. A. M. and will show at the exhibition of that organization at the Grand Central Palace from January 8 to 19.

The N. A. A. M. show is looming larger every day and in the accessory line it will probably be of such size as to compare favorably with the display in Madison Square Garden. The news was announced to-day that no dates had been given for the third show which was to have been held at the Palace. The management of the Palace would say nothing further and Mr. Longendyke, secretary of the A. M. A. A., was not available for a statement.

Aside from the twenty odd concerns members of the N. A. A. M. and not members of the Automobile Board of Trade, all of which will show at the Palace, the list given above will constitute an imposing array of exhibitors at the N. A. A. M. show.

At the offices of the Motor and Accessory Manufacturers it was announced that circulars had been issued to its members asking that applications be made for space at either of the national shows. Drawings will be held October 4. In some cases the same concerns will exhibit at both shows and it is estimated that the total number of members of the organization will approximate 150 at each. Independent manufacturers will have an opportunity to display their wares at all the automobile exhibitions this year.

With regard to the Garden exhibition, which will be of two weeks' duration, the car exhibitors will include only members of the organization. But there will be numerous companies outside its membership which will show other lines than automobiles. The motorcycle section, which will be housed on the Twenty-seventh street side of the Garden, will be far more complete than ever before.

New Motor Speedway

EARLY last week was incorporated in Trenton, N. J., the Metropolitan Motor Speedway Association, whose object, as stated in the incorporation papers, will be to conduct races, contests, exhibitions with automobiles, balloons, airships, etc. The incorporators named in the articles are I. Newton Quimby, Francis V. Dobbins and Edmund S. Johnson. The capital named is $1,500,000.

The location selected for the speedway, which will be a two-mile circuit, is on the meadows between Newark and Jersey City. The ground is at present a swamp, but the amount named in the articles of incorporation would seem to be quite sufficient to float the venture, for the ground is absolutely useless as it stands at present, and will be for years to come for any other purpose than that contemplated in the new incorporation. It is located about five miles west of the Hoboken Ferry, and could be reached from Columbus Circle in less than a half hour.

The course as planned will have but two real turns. On the south side, there will be a straightaway of 3,421 feet with two smaller straightaways on the backstretch—one 1,280 feet and the other 1,745 feet long. The track will be of sufficient width to accommodate large fields of starters, and so banked at the turns as to combine speed with safety.

The total amount of land involved is 330 acres, giving ample room for stands to accommodate 100,000 people and parking space for 10,000 automobiles. As regards accessibility, the new speedway is on the lines of the Pennsylvania; Delaware, Lackawanna & Western and Erie railways, including the new line from Manhattan Transfer into the Pennsylvania station at 33d street and 7th avenue. The Newark and Jersey City turnpike is on the south side of the proposed speedway, and the Belleville turnpike touches its northeastern corner, the trolley line of the Public Service Railway Company following the former from Jersey City to Newark.

Glidden Has 50 Entries

ABOUT two weeks from the date set for closing entries for the 1911 Glidden tour, the list contains 50 names and from present indications will be increased to at least 75 before the time limit has elapsed. The additional names that have been placed on the list during the past week include the following: E. R. Brackett, Jacksonville, Fla., Stoddard-Dayton; Atlanta Ad Men's Club, Atlanta, Ga., Corbin; R. S. Hall, Ocala, Fla., Cadillac; J. Epps Brown, Atlanta, Thomas; Charles Crook, Atlanta, Ga., Packard; Bob King, Anderson, S. C., Mitchell; K. P. McNeil, Jacksonville, Fla., Cadillac; L. C. Brown, Atlanta, Ga., Mitchell; St. Elmo Massengale, Atlanta, Ga., Garford, and Griffeth Implement Company, Athens, Ga., Schacht.

The pathfinding Flanders has finished its course and is in Jacksonville, after a pleasant and speedy trip. The worst roads of the tour were found the last day and at present a big gang of men is engaged in making improvements.

Plan of the proposed Metropolitan motor speedway on the meadows between Jersey City and Newark

Bird's-eye view of the new and modern plant of the American Simms' Magneto Company at Bloomfield, N. J.

BLOOMFIELD, N. J.—The main building of the new plant of the American Simms Magneto Company, occupying 4 1-2 acres. A unit type of construction has been employed, consisting of reinforced concrete beams and girders. The walls contain 18,942 square feet of glass with a wall surface of 16,500 square feet. There are 15,500 panes of glass, 3,100 feet of partition, about 1,400 electric lights, 1,000 steel lockers and 650 shaft hangers used for the support of shafting.

The power house is a separate building in close proximity to the main plant, and contains 6,000 square feet. There is an artesian well which goes down 560 feet on the premises, and supplies 65 gallons of water per minute for the boiler feed and drinking water. Between the power house and main plant is located a reservoir of 90,000 gallons capacity to collect the rain water for the purpose of neutralizing the artesian well water.

LOUISVILLE, KY.—The Dunham Auto Company has taken the agency for the Fiat car.

HARTFORD, CONN.—Kilby & Barrett have taken the local agency of the Bassel truck for this section.

GRAND RAPIDS, MICH.—The Ignition Starter Company has decided to remove its factory to Detroit.

LOUISVILLE, KY.—The Glenn - Bauer Motor Company has acquired the agency for the Broc electric.

LOUISVILLE, KY.—Oscar Erni, of New Albany, Ind., is the new agent for Inter-State cars in Louisville.

LOUISVILLE, KY.—The Wieland Company, 217 South Ninth street, has closed a contract to handle the Elmore car.

MINNEAPOLIS, MINN.—The Foster-Lawrence Company has been formed in St. Paul and will handle the Stearns car at 142 West Fifth street.

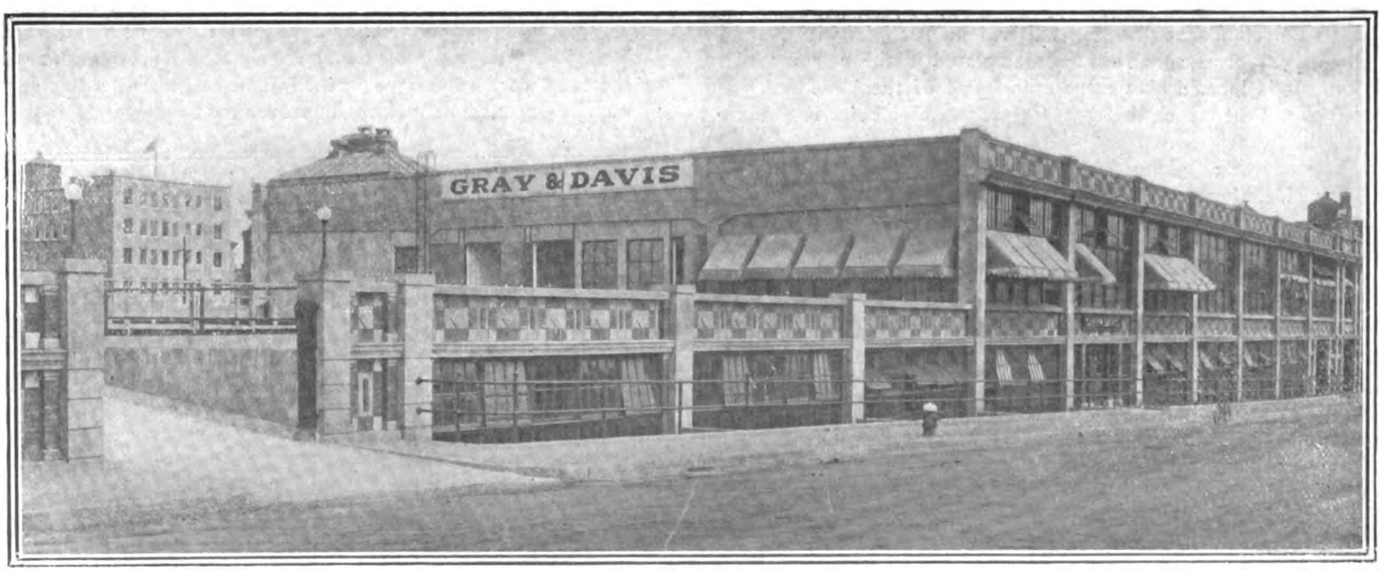
BOSTON, MASS.—The agency for the National car in Boston has been dropped by Frederick Randall, who has been handling it for some months.

TRACY, CAL.—C. A. Howard has taken the agency for Marion cars in San Joaquin County and will maintain salesrooms in Tracy and Stockton.

KANSAS CITY, MO.—On Wednesday last the entire stock of the McFarlan Six Sales Company was destroyed by fire. The loss is estimated at $5,000.

MANITOWOC, WIS.—Hagen & Van Akin have been appointed local agents for the Rambler and intend to build a garage and salesroom in the Spring.

COSHOCTON, OHIO—The City Council of Coshocton, Ohio, has enacted an ordinance prohibiting the use of any excepting rubber-bulb auto horns within the city limits and making it a misdemeanor for an autoist to leave his muffler open on the city streets.



The new Gray & Davis factory building, Boston, which is devoted exclusively to the manufacture of dynamos for use in automobile lighting. The factory is constructed entirely of cement brick

WASHINGTON, D. C.—The DeTamble agency has been given to the Ohio Motor Sales Company, who also handles the Ohio at 302 Sixth street, N. W.

BOSTON, MASS.—The Henry Motor Car Company that handles the Henry for New England is being reorganized so that it will have a larger working capital.

MILWAUKEE, WIS.—The Simplicity Steam Vulcanizer Company has opened a Milwaukee office at 403 Grand avenue under the management of A. S. Pierce.

SACRAMENTO, CAL.—J. L. Whitmore, proprietor of the Central Auto Company, of Stockton, Cal., has taken on the Chalmers agency for Sacramento and vicinity.

MILWAUKEE, WIS.—The Putnam Automobile Company has taken occupancy of the garage formerly owned by the Mau Automobile Company at 312 Twelfth street.

MILWAUKEE, WIS.—John S. Collins, of Saginaw, Mich., has been appointed manager of the Wisconsin branch of the Buick Motor Company to succeed George P. Hewitt.

BOSTON, MASS.—The F. R. Parker Company that handled the Elmore in Boston for several years has gone out of business and the Elmore is temporarily without an agency in the Hub.

LOUISVILLE, KY.—Edwin H. Chase, Jr., is the new manager of the local branch of the Olds Motor Works. He succeeds T. F. Smith, who returns to the factory at Lansing, Mich.

PHILADELPHIA, PA.—Announcement has been made of the removal of the Central Auto Supply Company to larger and better equipped quarters at the southwest corner of Broad street, Ridge and Fairmount avenues. The company deals in automobile tires, accessories and supplies, and motoring apparel for men and women. Frank Stehle is manager.

MILWAUKEE, WIS.—The George W. Browne Motor Company, factory distributor of Overland and Marmon cars, is now located in its new garage and salesrooms at 458-460 Milwaukee street.

STEVENS POINT, WIS.—G. A. Gullickson, of Iola, Wis., and P. W. Holton, of Nelsonville, Wis., have formed a partnership and will handle Ford business in this territory, with headquarters in the McDonald building.

COLUMBUS, OHIO—The Rusk & Hallock Automobile Company, located at 244 North Fourth street, Columbus, Ohio, has closed a contract to handle the DeTamble in thirty counties in central and southeastern Ohio.

MILWAUKEE, WIS.—The Goodyear Tire & Rubber Company, of Akron, Ohio, has opened a Milwaukee branch at 134-136 Oneida street, in charge of H. B. Ziegler, formerly traveling representative in this State.

BOSTON, MASS.—The latest concern to establish itself in the Hub is the Boston Motor Wagon Company. Salesrooms have been opened in the Motor Mart, Park square. G. Frank Davenport is manager of the new company.

SAN FRANCISCO, CAL.—The Oakland cars will hereafter be represented here by the Consolidated Motor Car Company, with G. A. Boyer as manager. This concern is also northern California representative of the Pope-Hartford.

MINNEAPOLIS, MINN.—Motorists in St. Paul want the fire department to standardize its warning signals on apparatus and then they will be willing to keep that style of sirens off their cars. They protested against a proposed ordinance prohibiting the use of sirens and other horns on all motor vehicles except those belonging to the fire department, hospital ambulances, police and fire insurance patrols.

SAN FRANCISCO, CAL.—The northern California agency for the Oakland car has been taken by the Consolidated Motor Car Company. The latter for the past two years has been distributor of the Pope-Hartford car exclusively.

MILWAUKEE, WIS.—The Oakland Motor Car Company, of Pontiac, Mich., has established a Wisconsin branch at 116 Mason street, Milwaukee, in charge of R. A. Creek. The local agent is the Smith-Hoppe Auto Company, 116 Mason street.

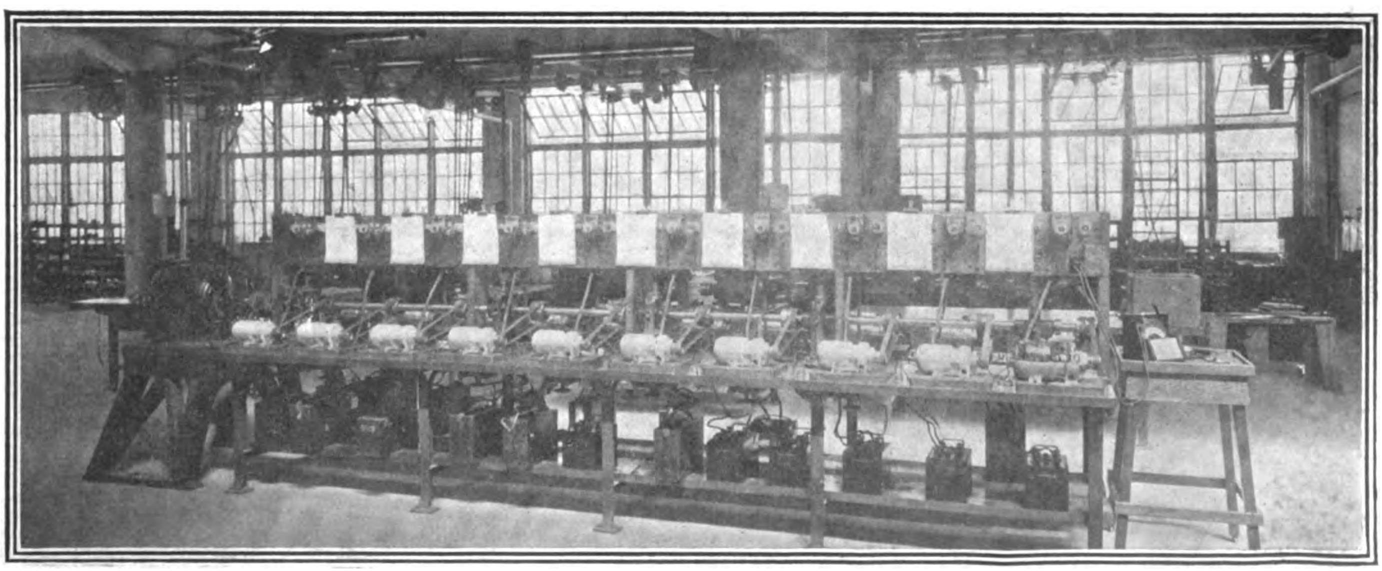
COLUMBUS, OHIO—Frank J. Girard, who was connected with the Curtin-Williams Automobile Company, of Columbus, Ohio, for eleven years, has taken the central Ohio agency for the Peerless. The agency is located at 174 North Fourth street.

SEATTLE, WASH.—F. A. Bardshar, manager of the Stevens-Duryea and Marion agency, has recently added the Maxwell car to his line. His territory will include the State of Washington west and north of the Columbia river.

KANSAS CITY, MO.—The Bond Motor Company, distributor for the Franklin, Everitt 30 and Krit cars, will erect a three-story building at 1615-1617 Grand avenue, in the heart of automobile row. The building will cost $60,000.

PHILADELPHIA, PA.—New and larger quarters have been established by the Century Automobile Sales & Supply Company at 520 North Broad street. The company will be the agent in Philadelphia and vicinity for the Pathfinder automobile.

SEATTLE, WASH.—George E. Johnson, manager of the Mitchell Motor Car Company, Seattle branch, was elected president of the Seattle Auto Dealers' Trade Association at the annual election held the past week. P. R. Sands, of the Flanders agency, was elected vice-president; Ira D. Lundy, of the Stoddard-Dayton agency, treasurer, and E. J. Strelau, secretary.



Test bench where dynamos for car lighting are tried out and checked to insure uniformity of service. Careful records are kept of the performance of each instrument during the trials

MILWAUKEE, WIS.—Walter S. Shawvan, who has been associated with the McDuffie Automobile Company, Wisconsin agent for the Stoddard-Dayton for several years, has been appointed Milwaukee agent for the Thomas Flyer.

SAN FRANCISCO, CAL.—B. F. Jacobs, sales manager of the Motor Car Manufacturing Company, of Indianapolis, has placed the northern California agency for the Pathfinder and Parry cars with the Motor Car Manufacturing Sales Company, of San Francisco.

KANSAS CITY, MO.—A change of managers has been made in the local United Motors branch. George W. Jones, former manager, has taken charge of the Des Moines branch and C. E. Hathaway, brother of the district manager, is now in charge of the local branch.

MILWAUKEE, WIS.—The Hichman-Lauson-Diener Company, 222-224 Fourth street, Milwaukee, Wisconsin distributor of the Ford, has leased the big garage and salesrooms of the McDuffie Automobile Company, Wisconsin agent for the Stoddard-Dayton, at 141-145 Eighth street.

LOS ANGELES, CAL.—There will be no auto show this year under the auspices of the Los Angeles Motor Car Dealers' Association. Final action on the proposition was taken at a meeting of the officials during the past week. The show was voted down by 19 against and only 8 for a show.

SAN FRANCISCO, CAL.—The local branch house of the Lozier Motor Company, of Detroit, is now permanently located in its magnificent new quarters on Van Ness avenue, close to the corner of Golden Gate, which is regarded as the center of automobile trade activities in San Francisco.

COLUMBUS, OHIO—The E-M-F & Flanders Sales Company is the name of a new concern organized to handle the E-M-F, Flanders and Flanders Electric in Columbus, Ohio. George R. Thomas is general manager. The salesroom and repair department is located at 264 North Fourth street.

LOUISVILLE, KY.—Exhibitors at the Kentucky State Fair this week included the following: Wilder Motor Car Company, Everitt car; Banks Motor Car Company, Ford car; Studebaker Corporation, E-M-F and Flanders cars; Louisville Auto Supply Company, accessories; Racine Auto Tire Company, Racine tires.

MINNEAPOLIS, MINN.—A deal for a three-story garage and sales building at 1629 Hennepin avenue was closed last week by L. W. Place, assistant general manager of the Olds Motor Works, of Lansing, Mich., with L. H. Fawkes. The structure, including property on which it is to stand, will cost nearly $100,000.

COLUMBUS, OHIO—The Broad-Oak Automobile Company, 622 Oak street, Columbus, Ohio, has taken the central Ohio agency for the Chalmers and Pierce-Arrow for the season of 1912. The territory covered for the Chalmers consists of eight counties surrounding Columbus and the territory covered by the Pierce-Arrow is ten counties.

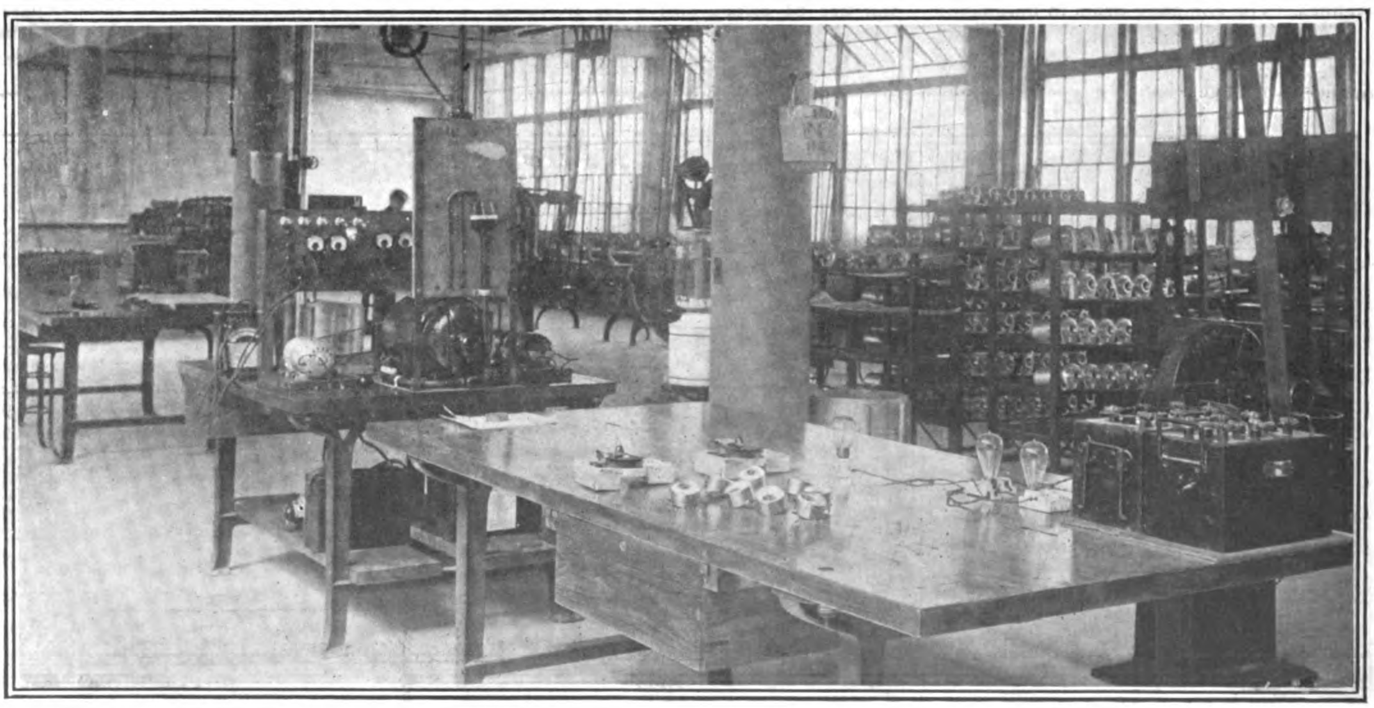
APPLETON, WIS.—Kenneth W. Brewer, formerly principal of Appleton High School and more recently traveling representative of the Baker Motor Vehicle Company, has organized the Brewer-Baker Company to distribute the Baker electric in Indiana and Kentucky. Headquarters have been established at 426-428 North Capitol avenue, Indianapolis.

GRAND RAPIDS, MICH.—The former Grand Rapids Overland agency and the Economy Garage have been merged and will henceforth be known as the Overland Motor Company, with salesrooms in the newly built garage on Island street. Repair rooms and day and night garage service will be maintained in the old fire engine house on Lagrave street between Island and Oak streets.

WASHINGTON, D. C.—Plans are under way to organize a sociability run from Washington, D. C., to Winchester, Va., on October 16, at which time the Glidden tourists will pass through that historic town. Winchester is the nearest point to Washington the Glidden tourists will touch and the run is being planned to give the national capital motorists a chance to see the big Glidden caravan.

WILMINGTON, DEL.—The T. C. Bradford Company, at Tenth and Tatnall streets, and the Wilmington Automobile Company, nearly opposite on Tenth street, have announced that they will handle new lines, the former having taken the agency for the Premier, and the latter for the Chalmers car and Alco truck. The Gomery-Schwartz Motor Company has established a Hudson-Garford agency at Fifth and Orange streets.

GRAND RAPIDS, MICH.—The automobile exhibit at the West Michigan State Fair was the largest in the history of that exposition. There were seven exhibitors as follows: Grand Rapids Auto Company, E-M-F and Flanders 1912; Moran Auto Sales Company, Maxwell; Overland Motor Company, Overland; John Vlasblom, 1912 Mitchell; S. A. Dwight, Everett; W. S. Farrant, Chalmers and Studebaker electrics; Becker Auto Company, Ford.



Where the inspections and tests are performed upon meters, instruments, cutouts, etc., at the Gray & Davis factory. The first bench is for general inspection and the second is used for the running tests

MILWAUKEE, WIS.—Jay E. Morehouse, State distributor of the Cole, has been appointed Wisconsin distributor for the Hupmobile, succeeding the Hearne Motor Company, Chicago and Milwaukee. Mr. Morehouse has leased the large garage at 82-84 Farwell avenue. The headquarters of the Wisconsin branch of the Winton Motor Carriage Company, which have been located with the Hearne branch at Eighth and Wells streets, have also been transferred to 82-84 Farwell avenue.

COLUMBUS, OHIO—The Hudson Motor Car Company, of Columbus, Ohio, 243 North Fourth street, agent for the Hudson and American in thirteen counties in central Ohio, has made the following contracts for subagencies for the coming year: W. L. Gage Automobile Company, Logan, Ohio; Madison County Automobile Company, London, Ohio; Charles W. Stevens, Newark; The Mader Auto Company, Circleville, and the Gaither Automobile Company, Springfield, Ohio.

SAN FRANCISCO, CAL.—A complete rearrangement of the agencies handling the tires of the United States Tire Company in northern California has just been effected. The distribution of the Morgan & Wright and Hartford lines has been taken over by a direct branch of the United States Tire Company, with headquarters at 414 Van Ness avenue. The G & J line is placed with Weinstock-Nichols Company, who until now have handled the Morgan & Wright line, and whose vice-president, A. D. Nichols, was the inventor of the Nobby tread. The Continental line goes to the Gorham-Revere Rubber Company. Chanslor & Lyon, former distributors of the Hartford tires, have taken the Pacific Coast agency for the Kelly-Racine tire.

NEW YORK CITY—The American Express Company has just placed its fifth repeat order with the American Locomotive Company for Alco trucks. This order calls for three more 3 1-2-ton trucks. With these three trucks the American Express Company has thirty-one Alcos in its service. Twenty-five of these are used in New York City and three in Chicago. The trucks just ordered will be placed in the New York service, and will be used for transfer work.

Automobile Incorporations

AUTOMOBILES AND PARTS

BOSTON, MASS.—Paddon Motor Co.; capital, $3,000; to deal in automobiles. Incorporators: Samuel N. Paddon, John Wilbur Paddon, Charles R. Codman.

CAMDEN, N. J.—Auto Chemical Fire Engine Co.; capital, $1,000,000; to manufacture self-propelled fire equipment. Incorporators: F. R. Hansell, I. C. Clow, John A. McPeak.

CHARLESTON, S. C.—King Automobile & Repair Co.; capital, $5,000; to deal in motor cars and repair them. Incorporators: S. B. King, Jr., W. A. King.

CHICAGO, ILL.—Packard Motor Car Co., of Chicago; capital, $50,000; to manufacture and deal in automobiles. Incorporators: Leslie J. Ayer, William Fogel, William L. Barnum, Jr.

CLEVELAND, OHIO.—Joseph Cormier Co.; capital, $2,000; to deal in automobiles, parts and accessories and to do a general machine and repair business. Incorporators: R. M. Calfe, J. G. Fogg, John F. Wilson, Joseph Cormier, Charles M. Selling.

COLUMBUS, OHIO.—Motorette Co., of Columbus; to sell Motorettes in its territory. Incorporator: H. B. McElroy.

DALLAS, TEX.—Munger Automobile Co.; capital, $2,500; to sell automobiles. Incorporators: S. I. Munger, Sr.; S. I. Munger, Jr.; L. R. Munger.

DAYTON, OHIO.—Heatherman-Solliday Motor Co.; capital, $20,000; to manufacture and deal in automobiles, parts and accessories. Incorporators: Frank B. Heatherman, Charles H. Solliday, Grace B. Heatherman, Zora Solliday, Joseph D. Chamberlain.

LIMA, OHIO.—Blevins Motor Sales Co.; capital, $5,000; to deal in automobiles. Incorporators: H. W. Blevins and others.

NEWARK, N. J.—Commercial Car Sales Co.; capital, $5,000; to sell automobiles. Incorporators: Joseph J. Rafter, John T. Walsh, John W. Phillips.

NEWARK, N. J.—Commercial Motor Truck Construction Co.; capital, $125,000; to make trucks. Incorporators: Wm. Dimond, J. True, W. Turton.

NEW YORK CITY.—Beasley Company; capital, $150,000; to manufacture, sell and store automobiles, machinery, etc. Incorporators: Robert F. Pratt, Albert E. Beasley, Thomas Moynam.

NEW YORK CITY.—International Auto Sales Co.; capital, $25,000; to sell automobiles. Incorporators: Henry J. Levy, David Schwartz, Aaron Klein.

NEW YORK CITY.—Morgan Sales Co.; capital, $15,000; to deal in automobiles and accessories. Incorporators: Pierre A. Proal, Chas. A. Duerr, Edgar B. Lynch.

RIDGEFIELD PARK, N. J.—Ridgefield Engineering Works; capital, $125,000; to manufacture engines, machinery, etc. Incorporators: Robert Burns, Jr., Samuel J. Katzberg, Daniel W. Steele, Jr.

ROCHESTER, N. Y.—Overland Rochester Co.; capital, $30,000; to manufacture engines, etc. Incorporators: Edward D. Creed, Royal R. Scott, Clifford F. Cribb.

YOUNGSTOWN, OHIO.—Cutting Motor Sales Co.; capital, $5,000; to deal in automobiles. Incorporator: J. B. Ditchon.

AUTOMOBILE GARAGES, ACCESSORIES, ETC.

BUCYRUS, OHIO.—Punctureless Tire Co. of Ohio; to deal in Dahl punctureless tires.

CAMDEN, N. J.—Stone Harbor Garage & Marine Railway Co.; capital, $85,000; to operate garages and marine railways. Incorporators: Charles L. Large, Louis H. Matthez, John D. Yarrow.

CHICAGO, ILL.—Sheridan Park Garage Co.; capital, $5,000; to deal in motor vehicles and conduct a general garage business. Incorporators: Harold H. Hart, James P. Doane, Marie Phillips.

JERSEY CITY, N. J.—Mechanical Rubber Tire Co.; capital, $100,000; to manufacture tires and other rubber goods. Incorporators, William T. Wheeler, Frank B. Crawford, Frederick Carter.

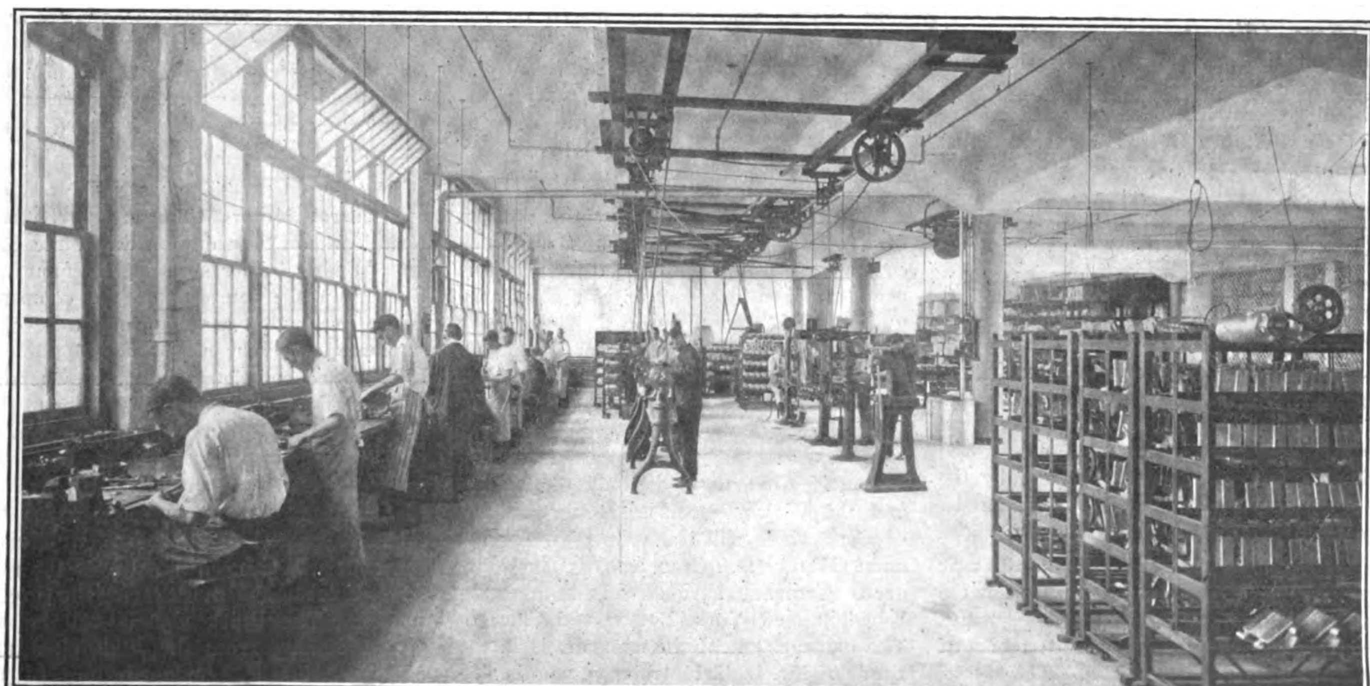
JERSEY CITY, N. J.—Metropolitan Motor Speedway Association; capital, $1,500,000; to conduct races, exhibitions and contests with automobiles, airships, etc. Incorporators: I. Newton Quimby, Francis V. Dobbins, Edmund S. Johnson.

LOUISA, KY.—Hays Oil Co.; capital, $10,000; to make and refine lubricants, etc. Incorporators: Tom Hays, G. R. Burgess, H. C. Sullivan, D. J. Burchett, J. L. Carey.

NEW YORK CITY.—Endurance Tire & Rubber Co.; capital, $10,000; to manufacture tires and other rubber goods. Incorporators: W. G. H. Randolph, Edward W. Tabor, James E. Bennett.

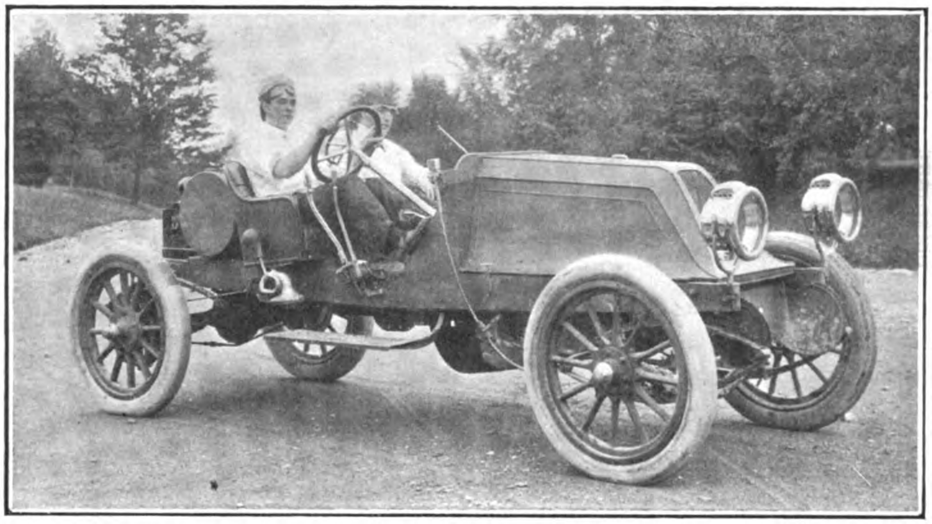
NEW YORK CITY.—J. H. Simms Co.; capital, $10,000; to manufacture and deal in automobile accessories, supplies, etc. Incorporators: J. H. Simms, C. F. Oscar, Arthur Meyer.

SIOUX CITY, IA.—E. C. McCormack Co.; capital, $10,000; to conduct a general garage business. Incorporators: E. C. McCormack, H. W. Hopewell.



Machine toolroom and assembling floor of the factory, showing a general scene in the interior of this important section of the new plant. Light is plentiful and space has been arranged with a view to efficiency

OF INTEREST to the INDUSTRY



New Franklin racing car recently built for Ralph C. Hamlin, of Los Angeles, Cal.

LOS ANGELES, CAL.—The Franklin Automobile Company has shipped to Ralph C. Hamlin, its local dealer, a racing car built on a model D chassis which Ralph C. Hamlin is to enter in the Los Angeles-Phoenix Desert Race November 4-6. The car may also be entered in the Los Angeles Motordrome and Santa Monica races. The chassis is stripped, bearing only the seats, gasoline tank and tool box.

ST. LOUIS, MO.—The Bond Motor Car Company, which has represented the Franklin Automobile Company in 26 of the 115 counties in Missouri, is to cover the entire State this coming season.

TOLEDO, OHIO—A deal was this week consummated by which H. H. Dennis, manager of the Rambler Motor Sales Company, of Toledo, will have the exclusive agency of the well-known Detroit Electrics in that territory.

CALGARY, ALBERTA—The Austin - Dick Company, of Calgary, Alberta, has been signed up as a dealer by the Franklin Automobile Company, succeeding the Alberta Franklin Company. The territory is the entire province of Alberta.

RACINE, WIS.—The Racine Manufacturing Company, one of the largest builders of motor car bodies in the country, has been obliged to establish a 24-hour-per-day schedule in most departments and by the end of the month will be working its entire plant all hours of the day and night.

ANDERSON, IND.—The Remy Electric Company has closed a contract whereby the Russel Motor Car Company, of Melbourne, Australia, will become general agent of Remy devices in that country. The Russel Motor Car Company is a large Toronto firm, with branches in the principal cities in Canada and Australia.

TOLEDO, OHIO—The local branch of the Buick company will be closed out on October 1, according to information given out by Manager George P. Dowling, and the northwestern Ohio business will thereafter be handled on an agency plan.

DETROIT, MICH.—Claude S. Briggs has resigned as general manager of the Brush Runabout Company to head a new motor car concern in Detroit. The new car will be named the "Detroiter" and will be built in two models—five-passenger tourist at $700 and a two-passenger roadster at $650.

DETROIT, MICH.—W. A. Crowe, of Detroit, Mich., who recently placed on the market a new car known as the "Crowe 30," is negotiating with the Industrial Association of Grand Rapids, Wis., for the establishment of the plant in the Wisconsin city. The car is designed by W. W. McIntyre.

DETROIT, MICH.—To market the product of the Marquette Motor Company, a sales company, known as The Marquette Company, has been incorporated as a subsidiary to General Motors Company. The officers are as follows: Thos. Neal, president; O. C. Hutchinson, vice-president and manger; James T. Shaw, treasurer; Standish Backus, secretary; T. S. Merrill, assistant secretary and assistant treasurer. The Marquette Company will handle the Rainier and the Welch-Detroit cars, likewise the new car which will be produced under the name Marquette. Branches of The Marquette Company have already been established in New York, Boston and Chicago. The management of the company is in the hands of Mr. O. C. Hutchinson, who is also vice-president. The headquarters of the company are 1302 Jefferson avenue, Detroit, Mich.

LIMA, OHIO—The following officers have been elected by the stockholders of the Gramm Motor Company: President, A. L. White; vice-president and general manager, B. A. Gramm; treasurer, W. T. Agerter; secretary, F. E. Lamb. The stockholders also authorized an increase in the capital stock from $500,000 to $1,250,000.

PHILADELPHIA—What is undoubtedly the most handsome and complete structure of its kind in Automobile Row has just been completed at No. 319 North Broad street and will henceforth be the Quaker City home of the Packard Motor Car Company, of Philadelphia. The new building is eight stories in height and built of steel and reinforced concrete, affording every facility for promptly and effectively handling the increasing business of the company and for rendering a most complete service to Packard users. The company owns the whole block on which the structure stands, 302 feet deep, upon which, should business development warrant it, the present building could be duplicated. The building is handsomely furnished.

FINDLAY, OHIO—The Gramm Motor Car Company, which removed from Bowling Green to Lima early last Spring, held its first annual stockholders' meeting at Lima last Wednesday and elected the following directors: A. L. White, B. A. Gramm, F. E. Lamb, W. T. Agerter and M. Bernstein. The capital stock of the company has been increased to $1,250,000. Of this amount $750,000 is common and the balance is 7 per cent. cumulative stock. The directors held a meeting immediately after the stockholders' meeting and elected the following officers: President, A. L. White; vice-president and general manager, B. A. Gramm; treasurer, W. T. Agerter, and secretary, F. E. Lamb.

NEW YORK CITY—Thomas Neal, president of General Motors Company, arrived in New York on Saturday on the White Star liner "Cedric," after spending the month in Europe in the interests of the company. While in London arrangements were consummated whereby the Bedford Motors, Ltd., passed completely into the ownership of General Motors Company. Prior to this time General Motors Company owned a part interest in the English concern, but through the new arrangement the Bedford Motors, Ltd., will be operated under the exclusive control of the big Detroit company. It will be used largely for the purpose of placing the Buick car on the foreign market. The Buick chassis will be exported directly from the Flint plant and completed in the London factory of the Bedford company, whence the cars will be distributed all over the transatlantic market.

PATENTS GONE TO ISSUE

COMPENSATING MECHANISM—A balancing gearset for the driving axle of motor vehicles.

4. As Fig. 3 shows, this mechanism for a two-section axle consists in principle of a drive member loosely sleeved over both of the meeting axle ends and provided with an internal divided chamber, a friction rim mounted on each of the ends mentioned within the internal chamber, and means within these rims to make separate locking engagement thereof with the drive member above referred to.

No. 1,000,870—to John Frank Rogers, Cleveland, Ohio, Granted September 12, 1911; filed August 10, 1908.

TWIST DRILL.—New and singular form of drill.

5. The drill is formed from a flat bar and has a tapered shank which is twisted alternately in opposite direction a number of times.

No. 1,002,846—to Frederick W. Hoefer, assignor to Hoefer Manufacturing Company, Freeport, Ill. Granted September 12, 1911; filed January 20, 1910.

MEANS FOR ENGINE COOLING.—A system proposed for internal combustion engines.

3. The invention covered by this patent (Fig. 2) refers to the combination of an internal-combustion engine cylinder, with a water reservoir, a blower receiving water in minute quantities from that reservoir so as to form moistened air, and a mantle around the cylinder where the moistened air is led to cool the surface of the cylinder. The reservoir is encased and communicates with the blower space, and means are provided connecting the mantle around the cylinder and the casing.

No. 1,003,290—to Roberto Fritz Emil Okrassa, Antigua, Guatemala. Granted September 12, 1911; filed May 13, 1910.

CLUTCH.—The combination of two members with a pawl.

1. This clutch is composed of a continuously rotating drive part and a driven member carrying a pawl movable to engage thrust portions of the driving member. The pawl is normally coacting with means for holding it back from engagement with the thrust portions mentioned and having a cam surface; a projection revolves with the driven member and at each revolution cooperates with the cam surface to move the above-mentioned means to normal position, a mechanism being also provided to shift the means retaining the pawl.

No. 1,002,853—to William H. Lanning, Jr., Toledo, Ohio. Granted September 12, 1911; filed June 12, 1911.

OIL CAN.—A positive-working oiler.

1. The oil can comprises a receptacle and spout, a spout-closing valve seated in the end of the spout, a valve for admitting air to the oil receptacle, means for opening both valves simultaneously, means for keeping both normally closed and locked.

No. 1,002,995—to August Ivar Johnson, Concord, N. H. Granted September 12, 1911; filed December 19, 1910.

RADIATOR.—Water-cooling apparatus of the cellular type.

3. The radiator has a vertical rear wall provided at its edge with a bead which projects laterally and rearwardly from the wall and which is provided at its rear edge with a rearwardly projecting flange adapted to support an engine hood, a peripheral wall being provided at its rear edge with a bead which projects laterally and rearwardly and which is secured over the head of the rear wall above referred to.

No. 1,002,978—to John M. Fedders, Buffalo, N. Y. Granted September 12, 1911; filed May 27, 1911.

VARIABLE-SPEED GEARING.—A combination of two shafts carrying stepped gears.

2. This patent relates to the combination in a variable speed mechanism, Fig. 1, of two parallel shafts, one driven and the other driving, oppositely stepped gears on these shafts, slides located intermediate these shafts adjacent the ends of the stepped gears and a bar slidably supported in the gears. On this bar is mounted an intermediate gear adapted to mesh with the opposite stepped gears, means being provided to shift the slides in order to move the bar laterally to bring the intermediate gear into or out of mesh with the stepper gears.

No. 1,003,221—to Gustav Wagner, Reutlingen, Germany. Granted September 12, 1911; filed July 15, 1909.

STEERING GEAR—A steering equipment of the worm block type for automobiles.

4. The patent refers to the combination with a steering wheel of a rotary stem on which the wheel is mounted and having its lower end journaled in a casing. A longitudinally movable member having a screw and nut engagement with the stem and slidably engaging with the casing mentioned is cut away at one side intermediate its ends. Through the aperture in the movable member a stationary tubular member within the rotary stem is secured to the casing, a stationary segment being mounted on this tubular member above the steering wheel; the tubular member contains a rotary shaft connected with a control lever. Through the cutaway portion of the longitudinally movable member passes a laterally extending shaft which is connected with the rotary shaft within the steering stem.

No. 1,001,258—To George W. Dunham, Detroit, Mich., assignor to the Hudson Motor Car Co., Detroit. Granted August 22, 1911; filed March 4, 1910.

Newest Ideas Among the Accessories

Norma Bearings

NORMA bearings, which are being manufactured by the Norma Company, Stuttgart, Germany, are now being introduced in the American market

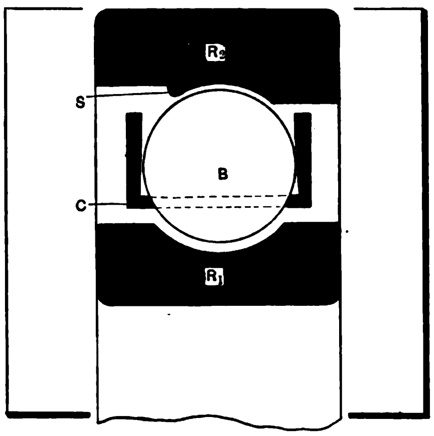

Fig. 1—Section of Norma annular ball bearing

by the Norma Company of America, 20-24 Vesey street, New York City.

The Norma annular ball bearings, illustrated in Figs. 1 and 3, have the outer race R_2 open on one side, permitting of disassembling the bearing altogether. It is possible to mount all parts independently of one another, they being of standard sizes and interchangeable. The outer race with its open side makes it possible to mount the bearing in inaccessible places, either with or without allowance for lateral play.

As the parts of the ball bearing in Fig. 3 show, the outer circumference of the inner race R_1 is shaped with an annular cavity C into which the balls fit. The cage is of brass, the walls having indentations to accommodate the steel balls which project through openings into the inner race, where they rest in the concave annular space. As the section, Fig. 1, shows, the inside of the collar is stepped off so as to take up end thrust if necessary. Norma ball bearings are made in standard dimensions for light, medium and heavy service.

The Norma roller bearings are shown in Figs. 2 and 4, and like the ball bearings are made with a high degree of accuracy, using the Hirth minimeter for the manufacture of the parts. The outer race R_2 of the roller bearings is open-sided, giving it the same advantages as those noted in the case of the Norma ball bearing. Short cylindrical rollers R which take the load are held and guided in a substantial steel cage by means of pins, being secured against skewing. The outer race is provided with a slightly convex track for the rollers; the inner race R_1 is a hollow cylinder, both races being securely fastened when mounted.

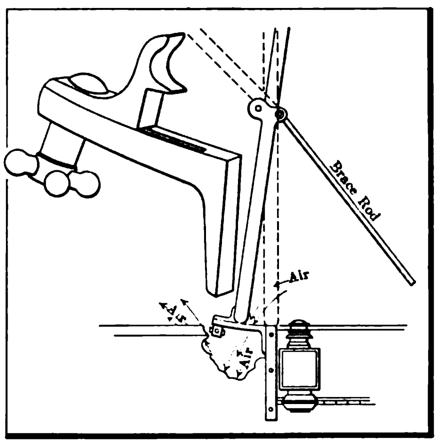

Fig. 5—Cyclone ventilator windshield and special brackets

The shaft of the roller bearing is capable of being axially displaced, but the bearing is not intended to take up thrust.

The dimensions of these roller bearings make them interchangeable with ball bearings of standard measurements.

Cyclone Ventilator Shield

In Fig. 5 is depicted the Cyclone Ventilator wind shield, made by the Sprague Umbrella Company, of Norwalk, Ohio. The construction of this shield permits of

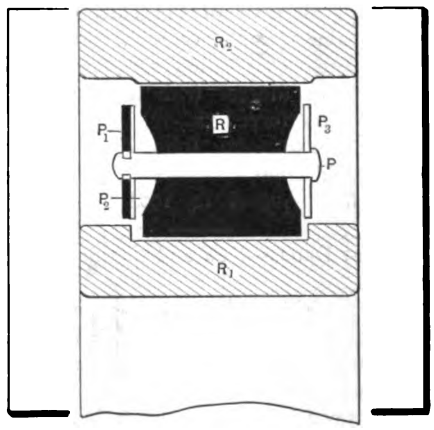

Fig. 2—Section through Norma roller bearing

placing it in such a position that the air current met by an advancing car is deflected below the cowled dash. The shield is attached to the dashboard in the manner shown in the cut, and while the position of its upper portion may be regulated by means of the brace rod illustrated, the entire shield may be moved forward or rearward owing to the special construction of the bracket shown in the upper left portion of the accompanying illustration, Fig. 5. The two feet of the windshield are rigidly fastened to such brackets, two of them being provided, and, as the illustration shows, mounted on a holder securely bolted onto the dashboard. This holder has a guideway cut in it in which slides a finger-wheel serving to hold the windshield in the desired position; it is loosened to move the shield and locked when it is desired to keep the shield in place.

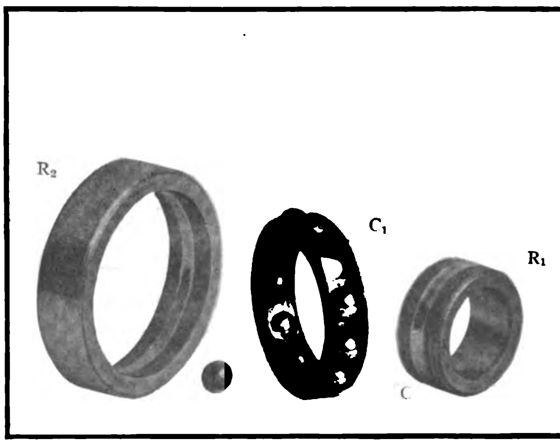

Fig. 3—View of disassembled Norma annular ball bearing

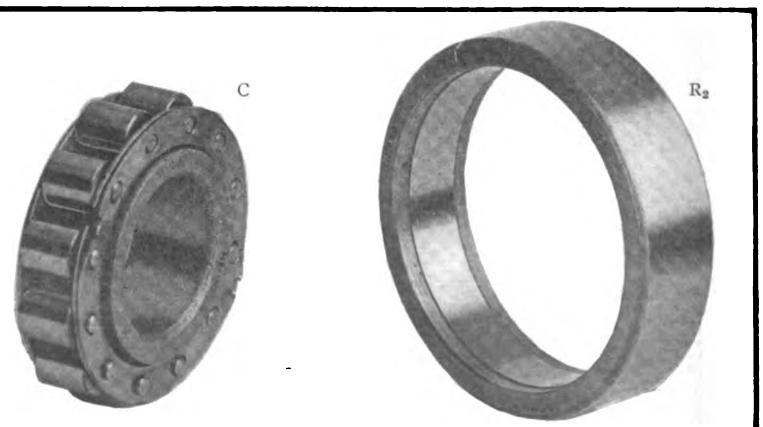

Fig. 4—View of component parts of Norma roller bearing

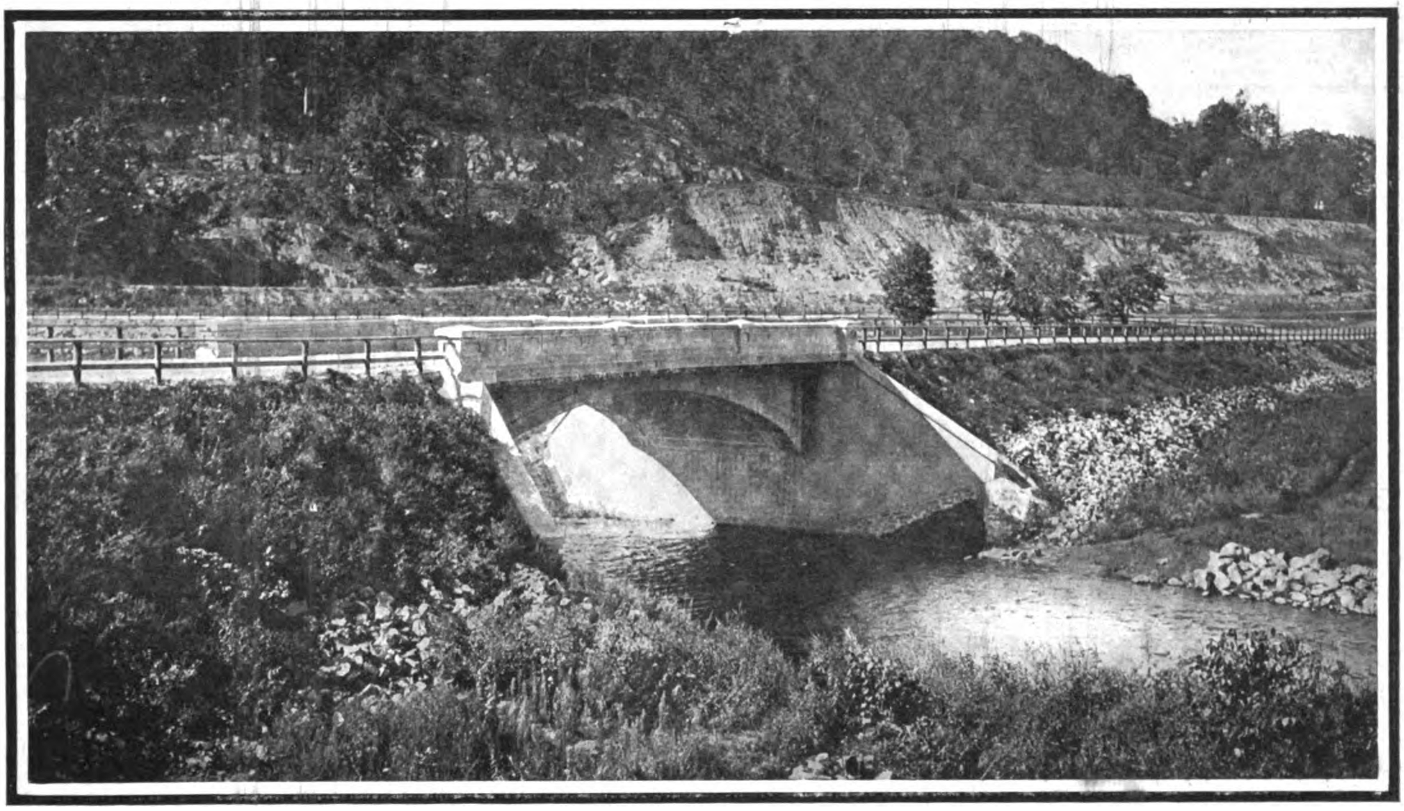
Vol. XXV NEW YORK—THURSDAY, SEPTEMBER 28, 1911—CHICAGO No. 13

THE AUTOMOBILE

Good Roads, Keynote of Prosperity

Automobile Has Forced Issue of Improved Highways



THE LAST WORD IN BRIDGE CONSTRUCTION AS IT APPLIES TO MODERN GOOD ROADS

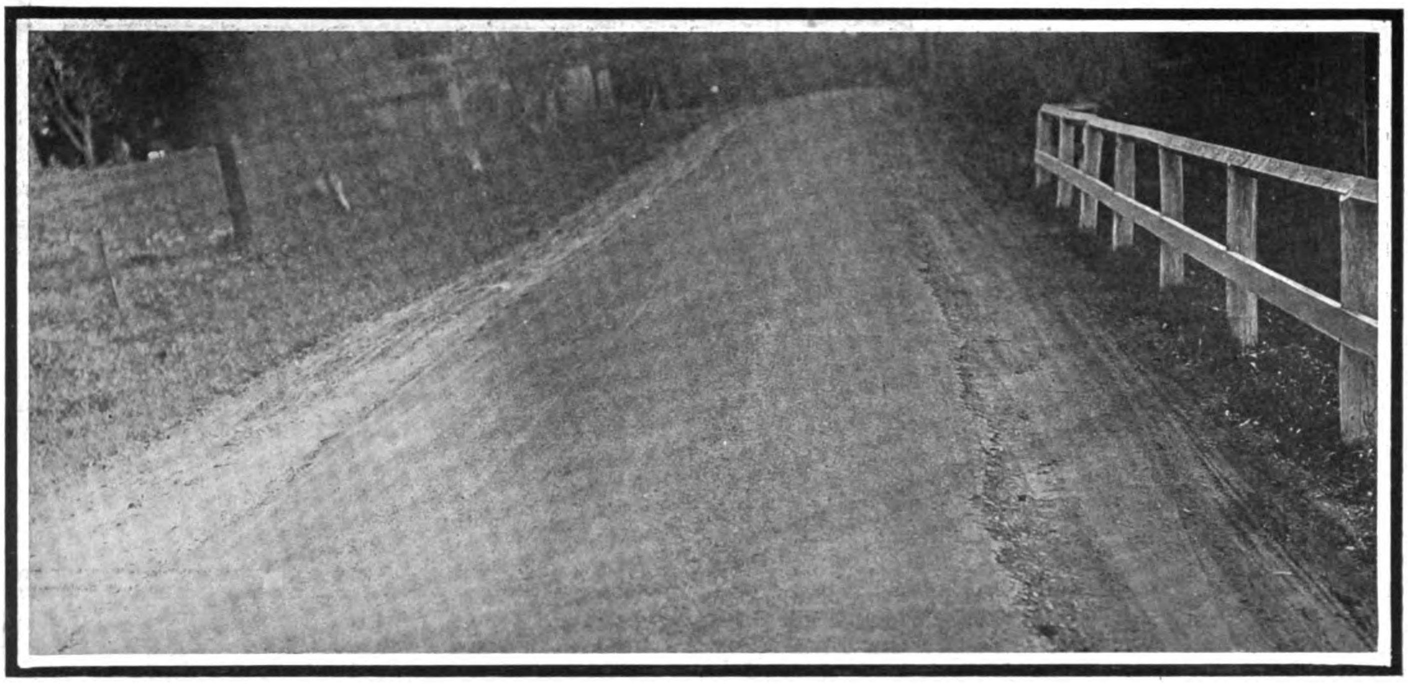
TRANSPORTATION measures the civilization of the world to-day, just as it has always done since the beginning of mankind. Each successive step upward that has been taken by mankind is founded upon speed and ease and the betterments of each in their relation with communication between more or less widely separated communities or individuals. The automobile is the highest form so far assumed by the idea of transportation, but in order to get the best results from the motor car goods roads are essential.

Next to the automobile itself the most important part of motoring is the road. In the broadest possible sense good roads mean prosperity and bad roads mean the reverse.

Of two communities equal in size and natural resources of surrounding territory, the one which has good roads will be found to be far in advance of the one where opposite conditions obtain, in every particular and factor that go to make up human well-being.

The automobile has forced the issue of good roads, as can be readily seen by one sweeping glance over conditions five years ago and as they are to-day.

At a banquet given in the New Kimball, Springfield, Mass., recently, during the inspection of New York and New England highways under the auspices of the Touring Club of America, Logan Waller Page, director of the Office of Public Roads, who acted as toastmaster, said that there were in the United States 2,155,000 miles of road and that $250,000,000 could be saved annually on the haulage of the three principal crops produced in the country if the roads were improved. On that basis the total



Two-thirds of this road is crowned so stiffly that horses are forced to the right. It is three years old

saving on the single item of agricultural haulage would amount to a staggering sum each year.

That is just one item of the advantages that would follow general road improvement. The others include practically everything that may be grouped as factors in human happiness, health and prosperity.

If the automobile never does anything more than center the attention of mankind on the roads, it has performed a mission that will surely have a high place in the history of civilization.

Five years ago a good country road was such a highway as could be traveled over in wet weather. Outside of a few boulevards and paved streets within the limits of certain cities there was no such thing as pleasure to be experienced in passing over the roads in any sort of a conveyance. To travel 10 miles in one hour behind a good horse would have been considered just cause for action by the authorities pledged to the protection of animals from cruelty, or from the point of view of a large part of the citizenship, just grounds for the appointment of a lunacy commission upon the driver.

This year practically $1,000,000 a day has been expended in building and maintaining highways, and in the future a still larger sum *per diem* will be devoted to this prime essential of civilization

State Aid, a system by which the various state governments assist by supervision, direction and by actual money appropriations in the improvement of county and township roads, has been adopted pretty generally throughout the country. The most progressive of the States have gone into the work with earnestness and some of the most astonishing results have been attained.

The federal government is mightily impressed with the importance of good roads, and, according to the annual reports of the Office of Public Roads, hundreds of object lessons in construction and good practice have been given to scattered communities.

The result of these labors is to be felt in the awakened interest of the general public in the subject of good roads. From every quarter of the land appeals for more education in the matter of road building and maintenance are pouring in upon the Government.

For five years practically every section of the country has been trying to improve its highways. In the East, Massachusetts, New York, Connecticut and New Jersey have made notable progress, but everything that has been done so far may be regarded in a broad sense as experimental.

It was a pioneer movement in which fundamental principles had to be discovered and applied to conditions that were amazingly complex. Some of the earlier specimens of road building in the United States are still in existence, while others have long since disintegrated. The fact that two specimens were made of identical materials and by the same process and subjected to the same volume of traffic was no good reason for the expectation of an equal return of service. It was discovered that slight differences in grades, drainage and the angle of the crown caused one road to go to pieces and the other to "stand up." But, on top of this, it was also found that the road that was destroyed in a single season in one locality proved satisfactory in another.

As a result the highway engineers are still considerably confused as to the lessons conveyed by these experiments. What one may consider as an established principle of road building another will regard as still to be classed among the experiments. The reason for this confusion lies in the variance of conditions covered by the road builders.

The experts and engineers confess frank-

Splendid view of machine used in Massachusett for spraying hot oil under pressure upon roads ly that the ideal road has not been found so far in their investigations, and most of them will add "and it is not likely to be found." By this they mean that a standardized and uniform method of road building, suitable for all conditions and all traffic, cannot be discovered.

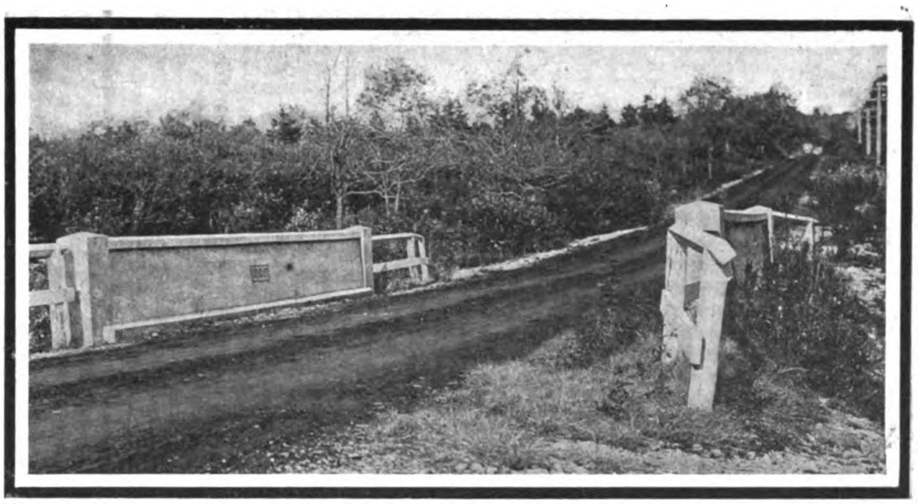
However, that admission is not nearly as important as it might seem at first glance. The time, money and energy expended in road work have not been wasted. An immense mileage of splendid, serviceable roads has been produced and is now in heavy service.

No man would appear at a formal social function, as a guest, clad in overalls. Neither would he work a pneumatic riveter high in the skeleton of a new skyscraper attired in the costume of the banquet hall. He would not promenade during a blizzard clothed in white duck, and he would not go to Coney Island on the Fourth of July in a bearskin overcoat.

There is a sense of the inflexible fitness of things that prevents the ordinary, sane human being from wearing clothing manifestly unfitted for the occasion, time and season. And thus it has been found with regard to roads.

But during the time that these experiments have been carried on the engineers have come by a vast mass of data having a distinct bearing upon the subject. They have been impressed with the necessity for good drainage, so that fine new roads may not wash out on the surface or break through into soft material which had been undermined by water.

In the widest sense good drainage is necessary for good roads. The use of tile pipes to carry off superfluous water has proved out excellently as far as subsurface work is concerned. Of course this is necessary in only limited degree, but where it has been given an adequate trial it has demonstrated its effectiveness.



Culvert building has been revolutionized since the automobile stimulated the good roads movement

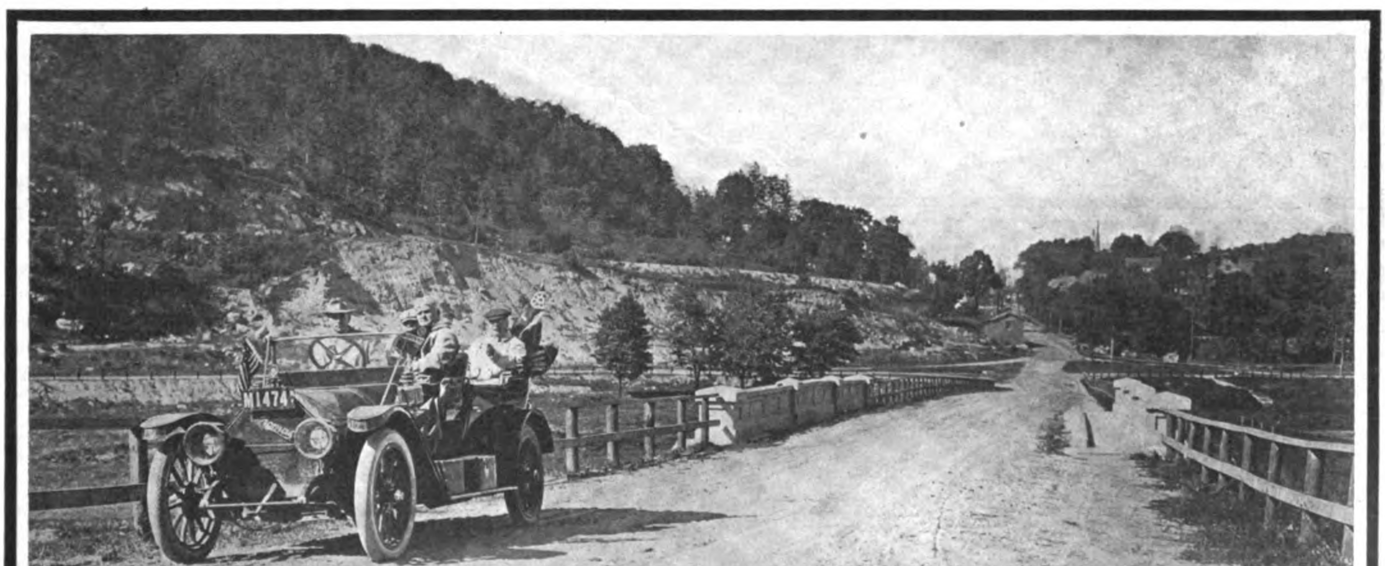
After a road has been surveyed, levels and grades established and such preliminary work as drainage has been performed, the next step, according to the conclusions of highway experts, is to lay the foundation. As a general thing, the foundation is spread upon a prepared bed; it may consist of coarse broken rock that has been screened to remove dust and minute divisions of the stone. Trap rock is a popular favorite, but in many cases where road-making material is at hand in quantity almost any other kind of rock is used. Unbroken gravel, screened to the proper size, is also a favorite material for surfacing the roads.

This foundation rock is spread to varying depths upon the prepared bed. These depths range from 4 to 9 inches and in some cases are even less. If the road is to be 12 feet wide the engineer directs that the lateral center of the road be raised slightly above the outside edges. This rise toward the center is called the crown of the road and serves the purpose of shedding water that falls or runs upon the surface.

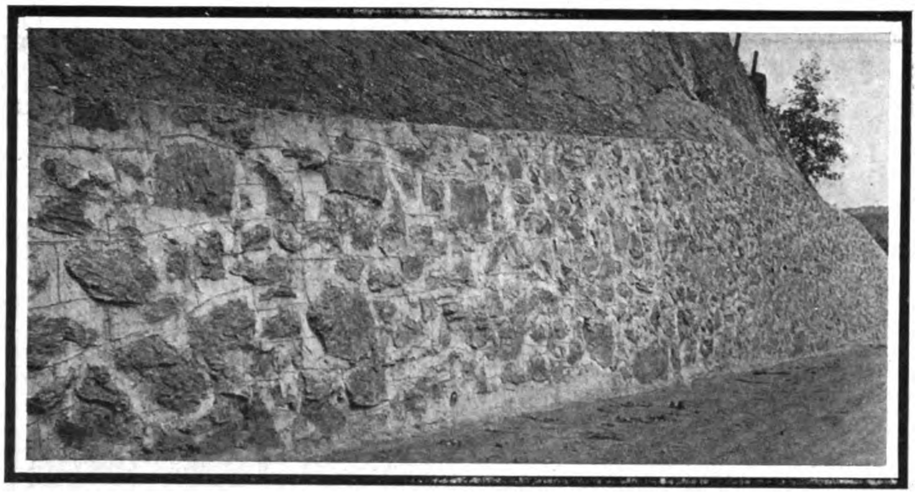
It is usually from about one-quarter of an inch to the foot (or 1 1-4 inches at the crest of the crown) to 1 inch to the foot, which in a 12-foot road would produce a crown elevation of 6 inches.

The next step in construction may be the application of tar, heavy oil or some form of binder. This step need not necessarily be taken at this stage of the procedure, but present practice varies so widely that it may as well be referred to here.

The binder may be spread on cold or distributed over the surface under high pressure and at high temperature. Tar naturally requires some heat, but heavy oil may or may not be heated. The results, as far as the heat or its lack are concerned, appear to be about the same.



Fine example of New York highway crossing scientific culvert; note loose surface, which is practically dustless and easy on tires



Excellent example of modern practice in making retaining walls to protect road surfaces

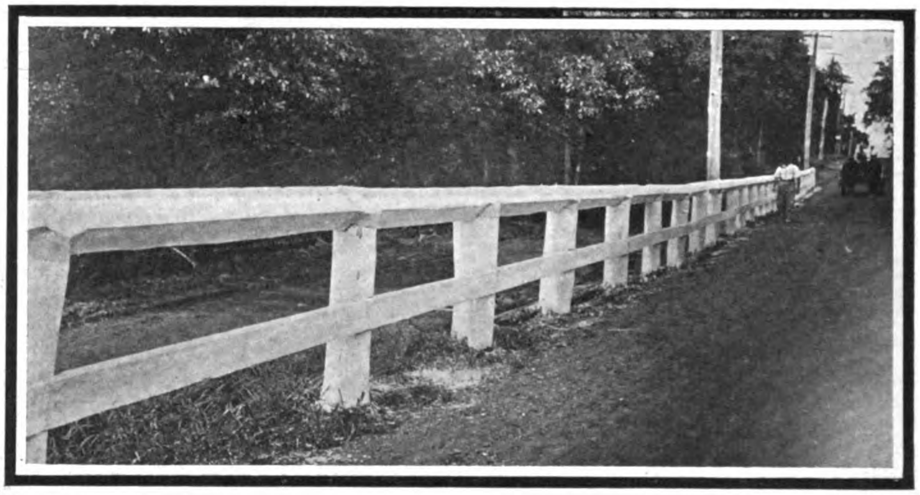
A magnificent example of the application of hot oil under pressure was afforded the visiting road officials during their recent trip through Massachusetts. A complete road outfit was at work making a stretch of improved highway a short distance out of Springfield and the party watched the progress with intense interest. The device that spreads the oil consists of a tractor engine, equipped with roller wheels, so that the surface to be oiled is first subjected to the pressure of the wide rollers. The tractor draws the sprinkling device, which includes a trailer tank wagon and a pump driven by steam for forcing the hot bituminous liquid through a line of flare sprays, directed toward the roadway. The oil is heated to about 220 degrees and is expelled upon the road surface at a pressure of about 80 pounds to the square inch.

About 7 feet in width of road surface can be treated with oil in this manner. After the passage of the machine an examination of the broken rock shows that each individual piece has been covered on all sides with the black, steaming fluid. In this stretch of road the large broken rock had been covered with stone of smaller size and the binder then been applied. Following the passage of the oiling machine, shovelers swept the oiled surface with gravelly sand. Hand rakes were employed to remove large stones.

Rolling immediately after sanding a new road has proved to be of only mildly debatable utility. The road commissioners seemed to agree that, if the crushed stone of various sizes could be laid and the binder applied, it would be better if the road could be allowed to remain undisturbed until the oil had a chance to properly penetrate. This should be several days at the shortest period or several months if it be possible to keep the road closed that long. When the work is taken up again there should be another oil treatment and the final surface of the road, consisting of peastone or some other material rolled into it to form a monolith, securely bound by the asphaltic oil, or whatever binder is used. Finer material is then rolled into place and the road is complete.

In a general sort of way the procedure as above describes the chief processes of modern road building. Such a road subjected to a reasonable amount of both automobile and horse traffic ought to last many years if properly maintained. In fact, almost any kind of construction is good if repairs are made when needed. There are some roads in Massachusetts that have been down four years and are still in good condition; some of them conform on general lines with the practice outlined above.

It costs about $400 a year to maintain a mile of properly built country road at high efficiency. Thus the cost of maintaining 100,000 miles of excellent highway, such as some of the roads traversed by the inspection party, would be $40,000,000 a year.



The modern fence is a thing of beauty and utility, being visible at night and nearly indestructible

It has been estimated that 100,000 miles of perfect roads would save much more than their maintenance cost each year in actual money, thus leaving the enhancement in value of farm property; the improvement in living conditions in districts that are now considered to be isolated; and the sheer pleasure of using the roads for all purposes, as clear profit.

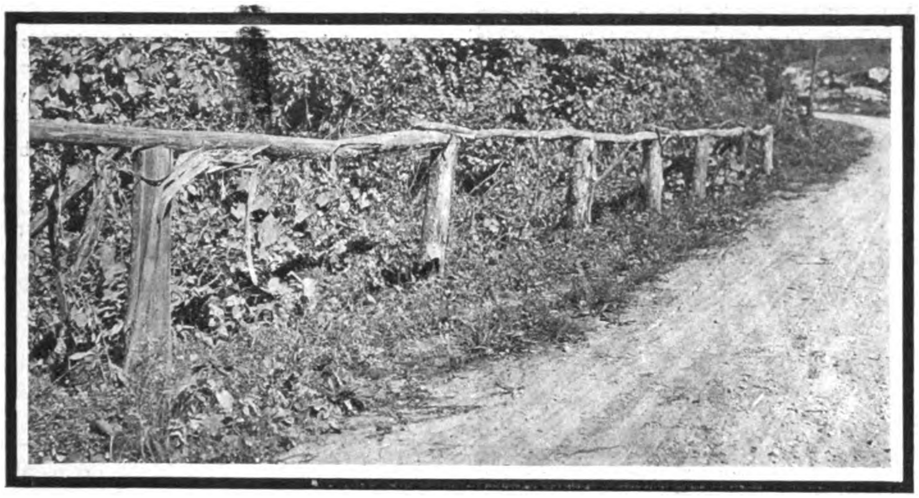
Among the associated problems that are intimately connected with road building are bridge and culvert construction, guttering and ditching, as well as the erection of fences to guard the right of way. Of the first of these incidents to road making nothing need be said at this time, as the engineering problems involved belong to another school. There has been a revolution in culvert construction within recent years. Where a small stream is to be

The small road roller and drag that are used in preparing roadbeds for their top dressing crossed and the span is not sufficient in size to require a real bridge the road engineers of to-day span the stream with a concrete culvert. This is securely founded and then built much the same as was its predecessor, the old stone culvert. The difference between the ancient and modern bridge of this description lies in the latter's strength, beauty and utility, which is about as much as can be said for anything that is made with human hands.

One type of curbed and guttered highway that is probably a good example of the road of the future

In any hilly country culverts are very frequently necessary and in Massachusetts there are literally hundreds of them included in the highway system. Some are as large as small bridges, while others are only large enough to allow the seepage of a stream a few inches in width.

Gutters are used largely where the prepared roadway extends the full width of the highway. Their use will probably be much more extended in the course of a few years, when the art of road making has progressed one step further. The best examples of guttering are found within the limits of some of the cities. Classed along with the stone gutters are the retaining walls, where cuts into the sides of hills have been necessary. They both serve the same purpose in different ways by protecting the road surface.



Old-style fences such as this one are out of place on the modern road and dangerous to traffic

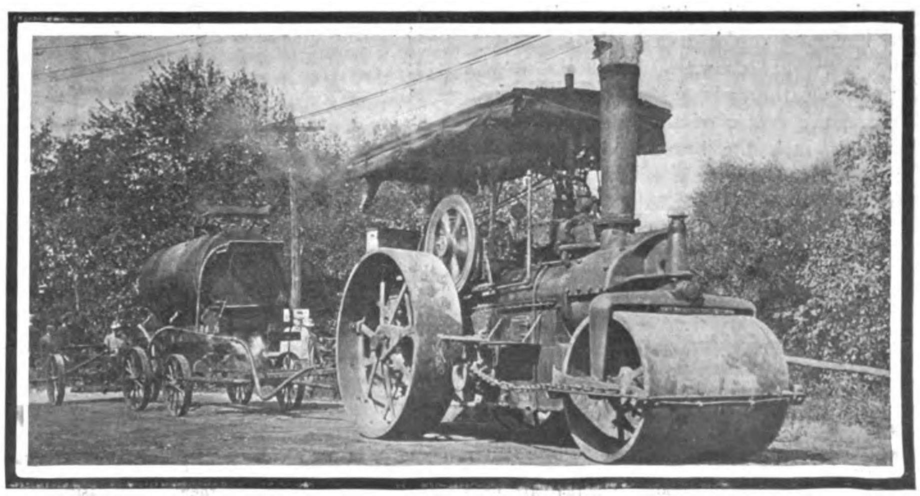
There has also been marked progress in the building of fences at dangerous points along the highways. The old style included nearly everything in the way of a fence from the proverbial snake and rider to dangerous barbed-wire; but the modern examples, such as may be found along any of the recently improved roads in New York and New England, are businesslike structures made with the rail in the form of a 6 x 6 beam, one angle of which is pointed upward and the opposite angle is set into sockets in the posts. These fences are whitewashed and the joints between the beams are covered in some sections with pieces of tin to protect the wood from the action of the weather. The reason for pointing one angle of the beams upward is twofold. In the first place such position has a tendency to prevent rotting by forcing the rain and melted snow to drain away and secondly no tramp has ever been able to solve the problem of sitting on the upturned edge.

The whitewash is an excellent idea as it helps the traveler to keep the road at night and warns him of possible dangers. These fences seem to shine out of the darkness and no cautious traveler ever need plunge into a ditch or off a culvert because of missing the road that is protected by them.

The chief lessons that have been learned in the past 5 years of experimentation and trial are these: The importance of maintenance; the significance of the angle in construction of the crown; the width and depth of road material, and the advantages that attend separation of the various classes of traffic.

It has been shown that nearly all of the methods of road building are good if the roads are maintained, and New York State has grasped the meaning of the lesson with a tremendous grip. There are some new highways in the State that are under the patrol system in more perfect form than it has assumed anywhere else in the country. This system consists in stationing a man in each 6-mile stretch of the highway under patrol. Material for mending the road is placed at intervals along its whole length and the man is furnished with a horse, tank-wagon and tools. It is his duty to keep his 6 miles of highway in perfect condition at all times.

As is shown in three of the illustrations, this process is perfectly practical. The man keeps on the road every working day in the year. When he finds a spot that gives signs of raveling he picks out the



Tractor roller, drawing hot oil tank and pressure oil-spraying machine damaged surface and resurfaces the spot. This may require him to dig clear into the lower strata of the road surface and the replacement of all the smaller material that was bound in originally by the builders. Then he oils and surfaces the spot, using tamper and rolls, and when he leaves it the repaired place is hard to find.

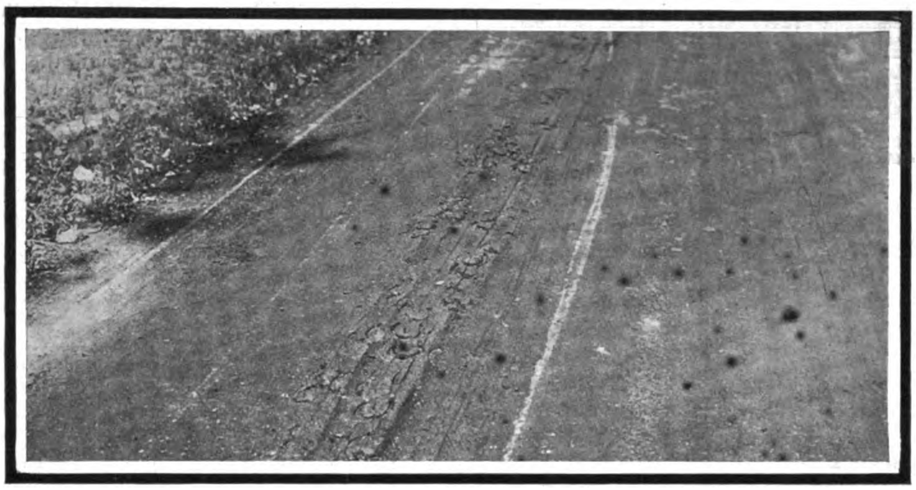
It has been found that the patrolmen take a great pride in the character of their work and seek to excel others employed in the same line. If the cost of maintenance is placed at $400 a mile per year, and the material costs the State $150 a mile per year, the income of the patrolman from his 6 miles of highway would exceed that of the average skilled artisan.

The result of the system is delightful to the automobilist who is fortunate enough to travel over patrolled roads.

When the horseshoe calks penetrate the macadam, the end of the road is in sight

Next among the cardinal lessons that have been learned is that which has to do with the angle at which the crown of the road should be constructed.

According to Frank D. Kemp, of the Massachusetts State Highway Commission, the travel of automobiles alone does not wear out road surfaces with anything like the rapidity of destruction that follows horse travel, or, worst of all, the combined effects of horse and automobile travel. It has long been recognized that the horse cannot draw a load over a road that is steeply crowned, especially in wet or cold weather. If the proportionate rise toward the center of the highway exceeds one-half inch the horse has his troubles in using the road. He slips and flounders from side to side and makes a bad job of it when the surface is wet or frozen. With only a slight rise in the crown the horse does well enough.



Note the effect of horse traffic on this newly repaired surface

On the other hand, the road crowned even as stiffy as is represented by 1 inch to the lateral foot will not stop the motor car. As long as the grades are not too heavy and the crown is not so high and pointed as to strike the underpinning of the car, the automobile can use such a road to advantage.

Mr. Kemp drew his conclusions from observing several stretches of State road under his personal supervision. One typical piece of highway was crowned in the proportion of about three-quarter inch to the foot. This road was 12 feet wide; consequently the crown in the center was 4 1-2 inches higher than the outer edges of the roadbed.

This proved to be too much for horse traffic and as a result the wagons proceeded along the side of the improved roadbed. This caused considerable raveling of that edge, but it left the high-crowned road to the exclusive use of the automobiles. At this particular point several important transverse roads lead into the main highway, and for a space of 6 miles this single road represents the only artery of travel to several populous local centers as well as the through travel. The road was improved 3 years ago and has not been touched since.

Of course, where the horses and wagons have broken down the edge of the macadam, the damaged surface extends well toward the center of the crown, but where the cars run the road is in excellent condition. This proves to Mr. Kemp that automobiles operated within the speed limit are not an important factor in wearing out the roads used only by themselves.

But it is a different story where the travel is mixed. So far in the progress of good country road building nobody has discovered a surface that will withstand heavy mixed traffic. Of course, granite block laid in concrete will support anything that has ever been devised in the way of traffic, but aside from the expense of such pavement its disadvantages are too appar-

Where a calk wound has allowed water to penetrate, causing destruction of the road surface

One of New York's highway patrolmen working to keep his section in good condition

ent to dignify by consideration. The problem is country roads, and so far the mixed traffic of horses and automobiles has proved too strenuous for existing types, unless some such system of maintenance as the patrolmen of New York may be excepted.

There are literally thousands of examples of the truth of this in each of the New England States. Given a stretch of highway, constructed of approved material under approved methods, and if the crown is low enough to admit horse traffic along with the automobiles the life of that road is short. The effect of horse traffic is this: The calks with which horseshoes are equipped, to prevent the animal falling on slippery surfaces, dig into the new road surface. This is necessary from the horse's point of view, but exceedingly bad as far as the road and the automobilist are concerned. The effect of the calks is to loosen the surface, and when this process takes place in the fall it spells disaster to the road.

The rain and snow descend upon the road surface and after soaking into it come to a stop above the waterproof oil and tar except in such spots as have been pierced by the calks. There the water trickles through to the under layer of the road material and in the course of a considerable wet spell the lower strata adjacent to the calk wound are filled with water. Then when frost strikes hard and deep the damage is done. Water expands nine per cent. of its volume when converted into ice, and road material is not strong enough to withstand the fierce pressure of the swelling ice. There can be but one result, and that is for the surface of the road to bulge up, torn from its binder and separated into its integral parts.

When the Spring comes on and the roads dry the material pushed out by the frost is caught by the rapidly turning wheels of automobiles and soon decorates the surrounding country in the form of dust or is rolled into the ditch and carried away by the next rain. In its place is a hole that may cause a puncture or blow-out at any time and which gives the springs a twinge every time a vehicle passes over it. Let the process be repeated in the same place and it would surprise no road commissioner to find a hole there that penetrated to the roadbed.

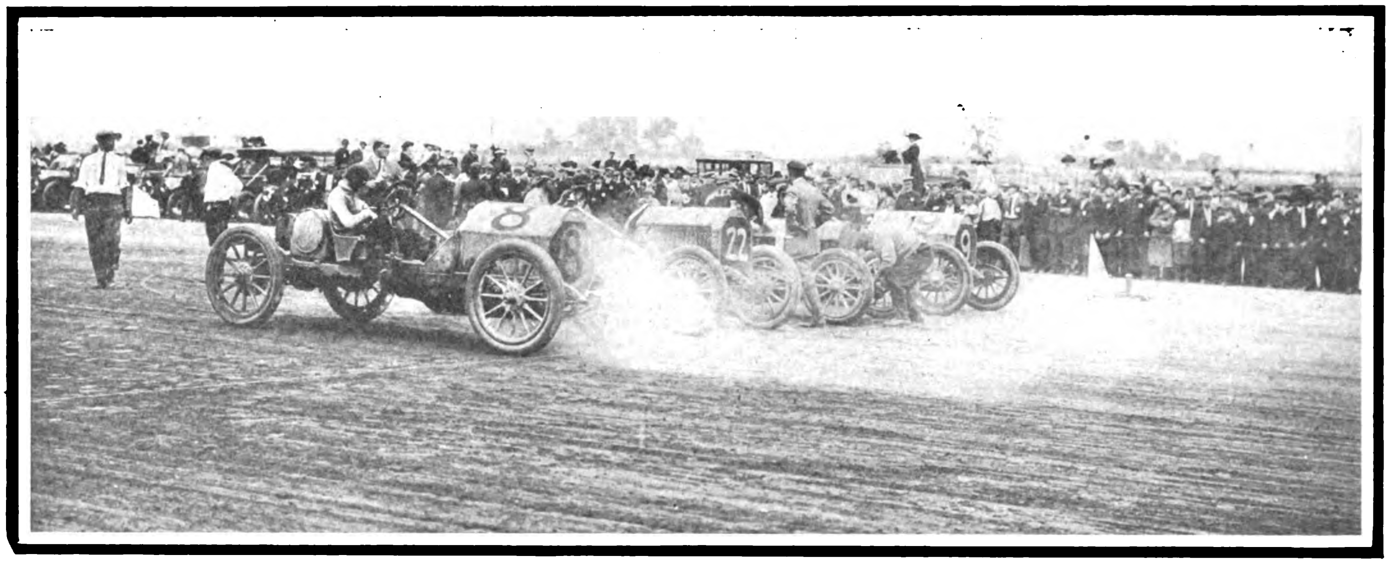
In a word the lesson learned from this phase of road building is that it is undesirable at the present stage of the art to allow automobiles and horses to use the same country roads. But as this is impossible to bring about under existing conditions, and as no road material will stand up under the mixed traffic unless carefully and constantly patrolled, the conclusion is either to install a patrol system or to build the roads wider, with the crown to one side of the center. If the crown were high enough this would be sufficient to bar horse traffic from that side of the road. Then the question of keeping the automobiles on the high crowned part would present quite a problem.

Material for resurfacing and barrels of oil are distributed along patrolled highways in New York

The engineers believe that the most durable and satisfactory road of the immediate future will be one fully 9 inches deep and extending from one side of the right of way to the other. The road may be of almost any kind coming within the general classification "water-bound" and should be curbed and guttered. If some means could be devised to separate the automobiles from the horses, by crowning one side of the road higher than the other, or by making the apex of the crown approximately one-third of the distance from the right curb, or by putting in a low, stone curb, one-third the lateral distance from the left curb, the problem might be solved.

(*Continued on page* 551.)

The patrolman is obliged to go through all the processes of road building and repair

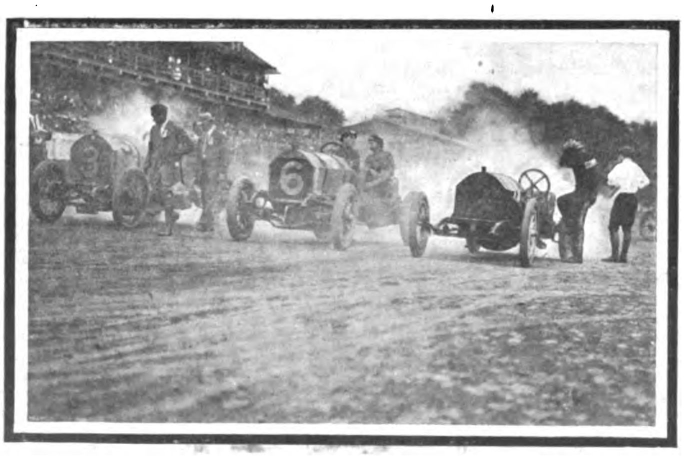


Start of the 25-mile race—Klinekar, Buick, Simplex, Klinekar—won by the Simplex, driven by De Palma

Simplex and Cino Win at Point Breeze

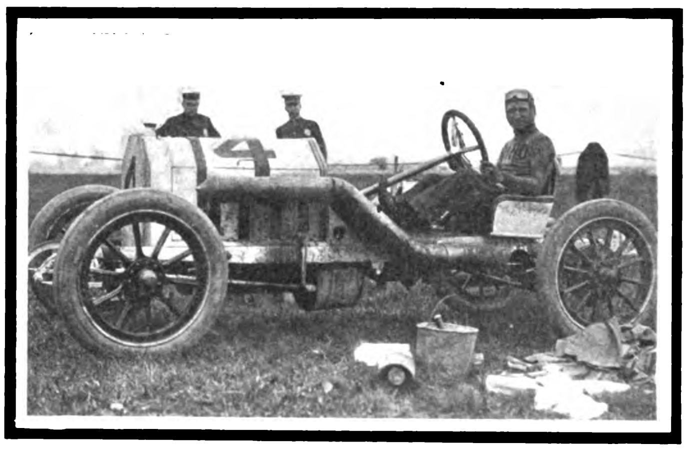
PHILADELPHIA, Sept. 25—De Palma, piloting a Simplex at the Point Breeze meet Saturday, smashed the mile track record of 58 4-5 seconds in the record trials, setting a new mark of 57 7-10 seconds; won the 10-mile open race, carded as Event No. 5, incidentally reducing the 5-mile track record of 5 minutes 45 seconds to 5 minutes 27 seconds, and setting a new mark of 10 minutes 42 seconds for the 10 miles; romped home a winner in the following event, a 5-mile free-for-all race, and finished up a good afternoon's work by winning the 25-mile special race with ease. In a special event, free-for-all handicap, however, he was forced to be content with third position, the winner of the contest having nearly a minute's start, almost a mile, a lead De Palma was unable to overcome.

Profiting by the unfortunate circumstances attending the race meet at Syracuse, N. Y., last Saturday, exceptional care was taken to avoid even a semblance of repetition of anything of the kind. The regular force of police that usually take care of the crowds was supplemented by extra forces on motorcycle, mounted and on foot, and spectators were roped off at a respectful distance from the track to prevent the more venturesome from letting their enthusiasm get the upper hand and straying too near the track for safety. As a consequence the races were void of the slightest mishap, without detracting in the slightest from the comfort and enjoyment of enthusiasts. The meet was the first one ever conducted by the Philadelphia Automobile Trade Association and the Contest Committee of that organization made a perfect job of it.



Line-up in the 10-mile race—Benz, Knox, Simplex—won by the Simplex

Only one event originally scheduled failed to come off—the ten-mile match race between Ralph De Palma, Simplex, and Louis Disbrow, Opel, due to the latter's machine being crippled while in transit to the track.



Cino, driven by Raimey, which won two races in impressive style

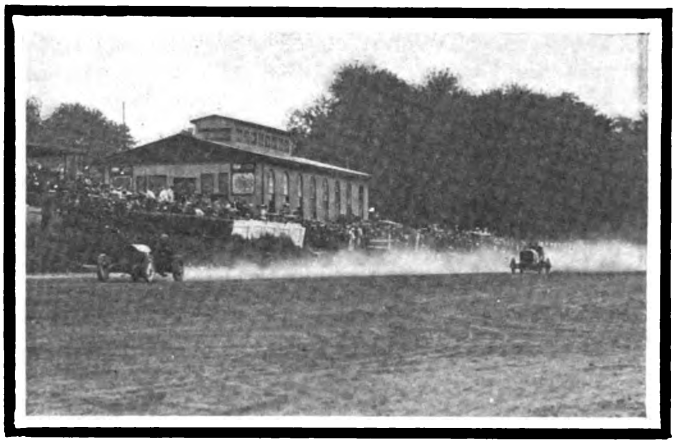
The record trials brought out three competitors—J. R. Raimey, Cino car, a newcomer to Philadelphia; Erwin Bergdoll, Benz, and Ralph De Palma, Simplex. The first two mentioned failed to cross the tape under the minute mark, and De Palma lowered the mark of 58 4-5 seconds established by Bob Burman in the Blitzen Benz recently.

Four cars competed in the second event, 5 miles. This race was notable for the fact that it marked the reappearance of Willie Haupt in racing. Haupt drove a Buick, but the car worked badly and he was forced to quit early. The race subsequently developed into a two-car affair, the E-M-F, Jack Tower driving, winning, with the Metz "Humming Bird" runner up. The next event was a repetition of the second insofar as the winner was concerned, the E-M-F again passing the judges' stand in the lead, the Klinekar, W. D. Morton driving, a good second, and the Abbott-Detroit third.

Only two cars finished in the fourth event, the Cino, J. R. Raimey driving, and Willie Haupt in a Buick. The former car started out in the lead and never relinquished it, although the Buick was always a dangerous factor and was in a good position to jump into the lead upon the slightest sign of a let-down on the part of the Cino. The latter won by about 100 yards.

Event No. 5, a special race with two starters, De Palma, Simplex, and Bergdoll, Benz, was provocative of daring racing and a great deal of excitement from the fact that the two machines were rarely more than 10 yards apart at any time during the 10 miles. A Knox car that had been entered in this event was ruled off on account of bad tires. It was during this race that De Palma set a new mark of 5.27 for 5 miles and 10:42.07 for 10 miles. Bergdoll also was well under the old record of 5.45 at the 5-mile mark, and although the crowd rooted hard for him to win, he finished a scant 3 seconds too late.

The Simplex also captured the following event, a free-for-all,

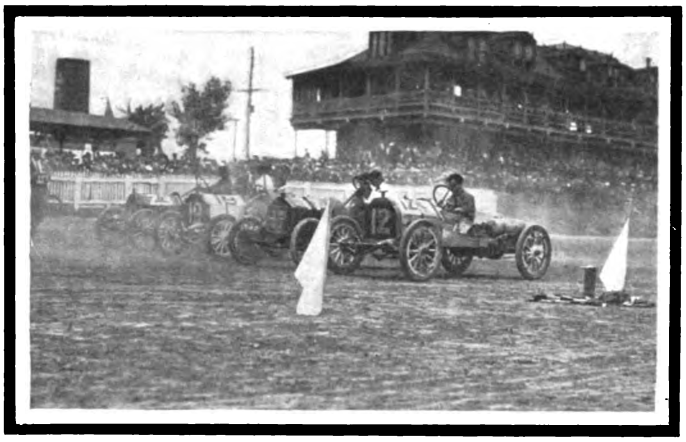


Simplex (De Palma) finishing ahead of Benz (Bergdoll) in 10-mile event

5 miles, with four starters, although it had its work cut out from the start.

In a free-for-all 10-mile handicap George Parker, a Philadelphian, driving an Ohio car, was returned a winner against four other contestants. Parker made good use of his allotted handicap of 55 seconds and after the fourth lap was never headed. The other cars in this event were Simplex, De Palma; Buick, Haupt; Klinekar, Seachrist; Cino, Raimey, and another Klinekar.

Two 25-mile races were an important feature of the afternoon, in one of which De Palma scored his third win of the day, the Cino being the winner in the other.



Start of $1000-and-under race—Hupmobile, Buick, Metz, E-M-F—won by latter

SUMMARIES OF THE POINT BREEZE RACES

Record Trials, 1 Mile

Pos.	Car.	Driver	Time
1	Simplex	De Palma	57.70

The Big Saurer broke through a bridge on the third day of the test

20 Clean Scores in Chicago Truck Run

CHICAGO, Sept. 25—In a nutshell, the story of the three-day truck demonstration of the Chicago Motor Club is this: Thirty-two power wagons started; twenty-eight finished; four were penalized in the road test; four more went out under the technical examination; one was penalized in the brake test and two in the clutch test, leaving twenty of the contesting cars with perfect scores in every department.

So far as the road work was concerned, the test came to an end Wednesday night, when the run to Chicago Heights and return was finished. Then the trucks were garaged until yesterday, when the technical committee inspected them. The brake and clutch tests took place in the alley in the rear of the White garage. Paced by a pleasure car, the trucks were called upon to speed down the alley at the limit of their class pace. Each was given 50 feet in which to stop and every foot over that meant 1 point. Only one of the power wagons failed to do this, that being No. 3 Clark, which slipped 3 feet past the line while the hand brake was being used.

An interesting feature in connection with this test was furnished by the horse-drawn rig, No. 13, which made the trip to Chicago Heights and return in 2 days, while the motors made it in 1 day. It was decided by the technical committee that No. 13 should go through with all the formalities so far as possible and the two horses were driven into the alley and put to the brake test. Of course the driver could not use brakes, for in Chicago horse-drawn rigs do not have them, but the horses were called upon to show in what distance they could stop at a walk and again at a trot. Gravely they went through the stunt and in the walk they had the wagon at a standstill in 15 feet and in the trot they checked the vehicle in 28 feet.

The clutch test came next. In this each truck was called upon to demonstrate the condition of its clutch by facing an 8-inch curb. With the motor running at its maximum speed the clutch was dropped in and either the rear wheels had to spin or the motor kill to escape penalty. Two failed to come up to the requirements, one being No. 5 Sampson and the other No. 14 Adams, each being given 5 points. Of the three penalized in these two departments, two already had suffered on the road, the Adams and the Sampson, but the Clark lost its chances of a perfect score.

Following this the trucks were garaged and turned over to the technical committee for a final inspection. This was not anywhere near as rigid as in the case of the pleasure cars, the committee contenting itself by looking only at the essentials—the running gear, transmission mechanism and steering apparatus. No search was made for loose nuts or bolts or things of that sort which ordinarily bring penalties in pleasure car runs.

This examination robbed three of the cars of perfect scores. The greatest sufferer was No. 3 Clark, to whose score, already blackened by the 3 points in the brake test, were added 105 points—5 points for a broken spring leaf and 100 points for a

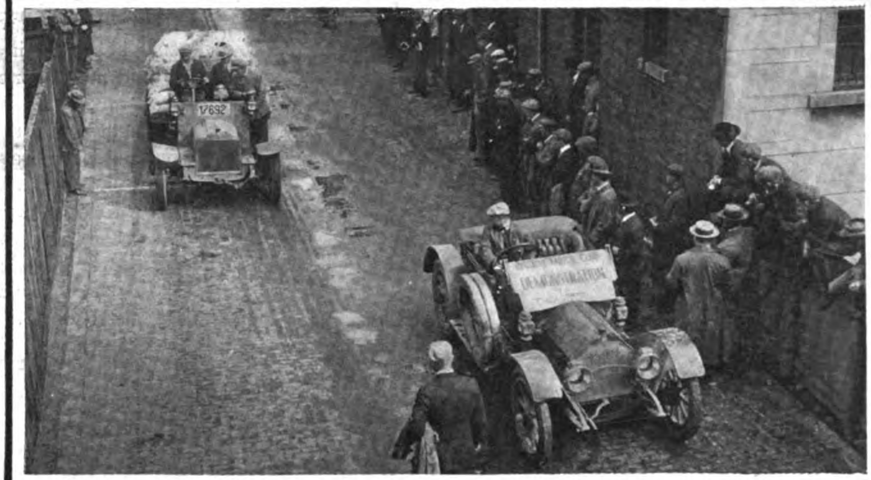
Not a few of the bridges had to be taken very gingerly by the heavier vehicles



The brake tests were held in a brick-paved street where the crowd was small and traction excellent

broken brake connection. No. 8 Krickworth was penalized 100 points—75 for a broken spring horn and 25 for a bent tie rod. The Krickworth had a gcod excuse, all the trouble being brought about by a skid into the ditch. Another perfect score went when No. 17 Lauth-Juergens was discovered to have two broken spring leaves, also caused by a ditch adventure. No. 18 Decatur was given 30 points for two broken spring shackles.

No. 1 Mercury won class 2K and its only opponent was another Mercury. No. 22 Stegeman won class 6K, in which the Reliance was the other contestant. No. 24 Mais had a walkover in class 7K, while No. 33 Sauer was alone in 10K.

Class 3K returns three cars as cup winners, No. 4 Buick, No. 6 McIntyre, and No. 7 Crown. In 4K No. 9 Clark, No. 10 Clark, No. 11 Le Moon, No. 12 Little Giant, No. 16 Lauth-Juergens and No. 20 Chase are tied with perfect scores. None finished in 5K, the McIntyre, the only starter, having quit the second day when it damaged its steering gear in a collision with a beer wagon. Class 8K, for the 2 1-2 and 3 1-2 ton trucks, was remarkable in that all four of the cars had perfect scores.

In Class 9K, in which four 5-ton trucks started, three went through with perfect scores, those being No. 29 Saurer, No. 30 Stegeman and No. 31 Sampson; No. 32 Alco, the other starter, was eliminated the second day by a burned-out bearing. No. 33 Sauer had a walkover in the big class.

The last day of the test, Wednesday, resulted in the elimination of only one perfect score, that being No. 5 Sampson, which was penalized 10 points for replacing a bolt in the torsion rod.

The routes included Whiting and Hammond, Ind.; Evanston, Oak Park and Chicago Heights, Ill.; but were largely within the limits of Chicago.

Lessons Drawn from the Run

The experience gained in the traffic zone within the loop appealed to the makers of 1-ton trucks more than to builders of 2-ton, 3-ton, 5-ton or 6.5-ton trucks, because the big trucks can make as rapid headway through traffic as the 1,000-pound delivery wagon.

The big trucks ran on a slow schedule of 5 or 6 miles per hour; this is the average speed through zones of congestion: but the smaller vehicles, running on a schedule of 11 miles per hour, found it impossible to average this speed in the traffic zones. They were held back at every corner by the policemen who allow the traffic to go one way at each crossing for a period of 1 minute and then let it go in the opposite direction.

Before the experience of one day in traffic, many of the makers of smaller trucks were guaranteeing as high as 15 miles per hour anywhere in the city for their trucks; but after 1 day of official demonstration they were willing to cut the guarantee to 10 miles per hour. One maker said that he would not guarantee over 10 miles per hour on his vehicles for congestion zones. It may be noted that when these little trucks got into semi-traffic-congestion areas, they were able to make an average of 15 miles per hour with ease.

This speed experience is one of the most valuable of the demonstration. Speed has been going against the commercial vehicle for months. The inexperienced salesman will guarantee any speed to 25 or 30 miles per hour and in addition would guarantee the truck for life. Such would-be guarantees are absurd;

Contestants held up trying to get around a gang of street repairers

they injure the business; they spoil sales instead of making sales; and they will eventually put the dealers out of business.

The one trouble which evidenced itself during the demonstration was that of hard tires. The solid rubber tire is imperative for heavy trucks, say from 3 tons up, and the trouble with it is in its coming off. When a solid rubber tire comes off, the wheel has to go to the tire repair shop before a new tire can be attached. The driver cannot put on a new tire on the road the same as with a pleasure car. Should a 5-ton truck lose a tire when 5 or 6 miles from the point of delivery, it would be necessary to get another wheel to the truck. This means that the truck owner should carry extra wheels, shod with tires, in stock. To get the wheel out to the truck takes time and time means money. From this demonstration it would seem that the demountable solid rubber tire is the only solution of the problem. It should be easier to supply a satisfactory demountable rim for a truck than for a touring car, because a solid tire is used. Some of the makers have such tires and rims but more of them are needed. On a 5-ton truck fitted with dual solid rear tires, the wheel with its two tires will weigh anywhere from 700 to 840 pounds. To carry an extra wheel around on the truck means quite an extra load in itself. To carry a single rubber tire with its rim would not be much over one-quarter of such a load. For trucks in which the motor is carried under a hood, the same as in a touring car, a single front tire of the same size as one of the dual rears could be used, so that one extra tire, carried on the truck, would be enough for all exigencies. On

Reliance truck plugging through mud one mile out of Chicago Heights

the other hand where the motor is carried under the seat, the seat being up in front, a heavier front tire is needed and this would make it necessary to carry two sizes of spare tires, which would be much preferable to carrying two extra wheels.

The truck must operate on schedule. If it does not, it loses money for the owner. It delays the shipment of merchandise to out-of-town places; it may cause cancellation of orders; it may do a dozen other things, solely because it loses a tire and has to be hung up on the street until a new wheel arrives.

From the table of truck weights, printed on another page of this issue it is apparent that some of the trucks are very heavy for the useful load they carry.

Examination shows that for loads of 1-ton and under, the truck weight approximates one-third more than the load it carries. In some of these, the truck weight is almost double that of the load capacity of the machine. In the 2-ton and 2.5-ton trucks, the truck weighs about 25 per cent more than the load it can carry. In the 3-ton and 3-5-ton classes the truck weight is not more than 14 per cent. in excess of the load carried. As the truck capacity increases the weight of the load and the weight of the truck approach one another, thus the Sampson No. 31 weighs 10,800 pounds and carries a load of 10,100, or 700 pounds less than its own weight. The two Saurer trucks were the only examples of the truck being much lighter than the load carried, thus the 4.5-ton truck, No. 29 weighed 6,790 and carried a useful load of 9,140, or more than 40 per cent. in excess of its own weight. Again in the 6.5-ton vehicle, No. 33, the

McIntyre, No. 6, which finished with clean score in Division 3K

truck weighed 8,380 and carried 13,145 or more than 50 per cent. over its own weight.

Many of the trucks are too heavy for the work they do. Much weight can be cut out in places. It takes motor power to carry the truck's own weight along, and if 2,000 pounds can be cut off the weight of a 5-ton truck, it should make the carrying capacity of that truck commensurately greater; it should reduce the tire upkeep on that truck; and it should reduce the general wear and tear. It is poor economy to load up with heavy parts if smaller ones will do. If ordinary steels will not give adequate strength without using enormous mass, then the natural solution is to use better steels and cut down the size of the parts. There is much to be done in this respect.

With the small delivery the proportion of car weight to load will never be as favorable as with the big truck, on the ground that a small truck requires almost as many pieces in its make-up as a big truck does. There is not much difference in the weight of a magneto needed on a small car and that needed on a big truck. The same holds true with many other parts.

As the brake table on another page shows, most of the contesting trucks were well braked. The rules allow 50 feet as a stopping distance in the brake tests. This is too much. For trucks of 5-tons or over and traveling at 6 miles per hour, 20 feet is distance enough. Some of them stopped in the amazing distance of 3 feet, others in 4, 7, 8, or 9 feet, with only one set of brakes used at once. Trials were not made to show what distance would be required when both sets were used together.

In the brake tests, with lighter trucks, the distances ranged from 20 to 50 feet. Many of the 1-ton trucks using large wheels, but not large enough drums, should have larger brakes.

The inadequacy of the brakes on the lighter vehicles was proven by the number of accidents these vehicles suffered by running into street cars, heavy horse trucks and into one another. Many of the accidents were due to the brakes locking the wheels and the truck skidding on the car tracks into street cars. This suggests the necesity of additional brakes.

When being operated in congested city traffic zones a 1-ton truck traveling 10 miles per hour should be able to stop in a distance of 20 feet, and if brakes cannot be fitted to accomplish this, then some additional form of brake, which would contact with the street pavement, might be introduced.

Locking of the wheels is the most dangerous factor in a brake for a solid tire and the designers should aim at a brake which will take hold gradually and not lock the wheels. Once the wheel, shod with a smooth solid rubber tire, is locked it loses obedience to all laws and simply skids. If in a street car track it will skid along a terrific distance; and if on a pavement it will wreck itself against the curb or some other vehicle. Larger brake drums will aid in accomplishing this end. The maker must not be satisfied with a brake that will simply lock the wheel, this is not the acme of brake perfection by any means, it must do more—apply gradually and retard the wheel, without destroying that friction condition between tire and street surface.

Little Giant, No. 12, came through the entire test without a single demerit

A sample of the street conditions met with in South Chicago on the first day

Georgians to Tour State and See Races

ATLANTA, GA., Sept. 25—Final plans for the Tour Around Georgia were made at a meeting held here recently. According to present plans the tour will start November 22 and last 11 days. Only 6 days, however, will be spent on the road. The rest will be in Savannah where the tourists will be on hand for both the Grand Prize and the Vanderbilt races.

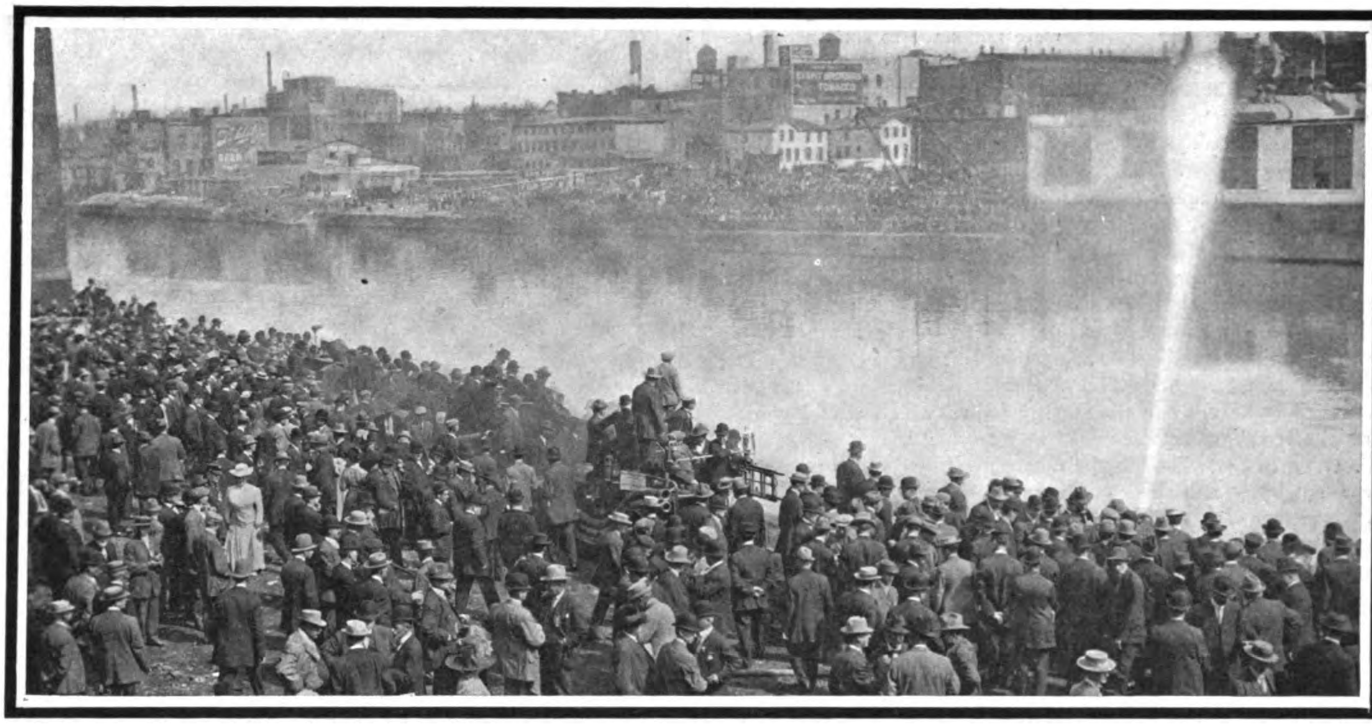
The exact list of prizes has not been announced, but already $3,200 has been subscribed for this purpose. The city of Savannah has made a special prize offer of $600 to the town or city sending the greatest number in proportion to its population.

The scheme is to start the tour from Atlanta, November 22. The first day's run will be to Americus, 149 miles, with a stop at Zebulon for lunch. The next day the tourists will journey to Valdosta, covering 137 miles. There will be a stop at Albany and a lunch at Thomasville. The third day's touring will get the tourists to Baxley, 133 miles; a noon control at Waycross.

The exact route of the fourth day's run, which is to Savannah, will be the subject of further scouting. The route is 105 miles.

In Savannah the tourists will have 5 days to view the two big races and to tour over Chatham County's excellent roads. After the running of the Grand Prize the tourists will take up their journey again. The first noon control out of Savannah will be Statesboro and the night control Doblin, 125 miles. The following morning the tourists will run to Macon and that night will complete their journey to Atlanta, 152 miles.

The heavy trucks weathered the mushy streets without great difficulty



Immense crowds witnessed the test of motor fire pumps at Milwaukee during the recent exhibition

Fire Chiefs See Apparatus Tested

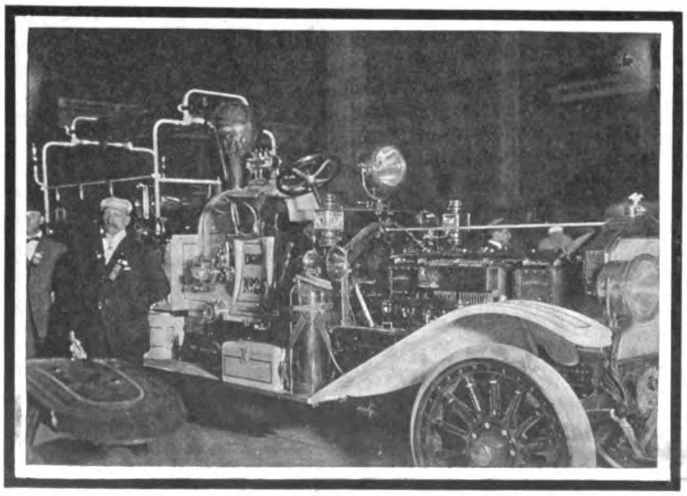
MILWAUKEE, WIS., Sept. 22—Motor-driven fire apparatus was the feature of the thirty-ninth annual convention of the International Association of Fire Engineers which closed here to-day. In fact, it was generally remarked that the parades and the exhibition at the Auditorium were as much a show of automobiles as of strictly fire-fighting rigs. Of the twenty exhibits of fire-fighting apparatus there was only one that was not gasoline propelled and only two pumping engines that were not operated by gasoline. One of those was a steamer which had been converted from a horse-drawn rig to a modern form by the substitution of a motor for the horses. In the pumping engine tests only gasoline-driven pumps took part.

Following is the official report of the tests:

Test No. 1. American-LaFrance Fire Engine Company, Elmira, N. Y. Double motor (six cylinder each) pumping car; horsepower of motor, 200; cylinders, 5 1-2-inch bore 6-inch stroke; pump capacity, 300 to 800 gallons per minute. Discharged 262 gallons per minute through 1,000 feet of 2 1-2-inch hose and 1 1-4-inch ring nozzle; pump pressure, 270 pounds; suction pressure, 5 pounds; net pressure, 275 pounds; nozzle, pressure, 56 pounds. Duration of test, 7 minutes.

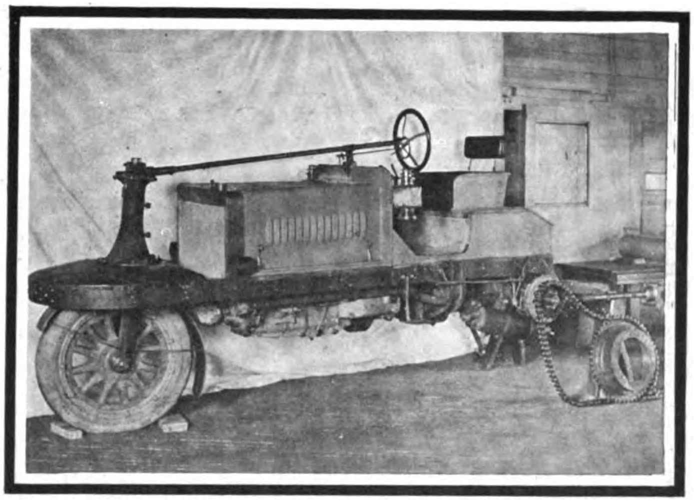
Test No. 2. American-LaFrance Fire Engine Company, Elmira, N. Y. Same machine as in test No. 1. Discharged 322 gallons per minute through 1,000 feet of 2 1-2-inch hose and 1 1-2-inch smooth nozzle; pump pressure, 275 pounds; suction pressure, 5 pounds; net pressure, 280 pounds; nozzle pressure, 23 1-4 pounds. Duration of test, 15 minutes.

Test No. 3. American-LaFrance Fire Engine Company, Elmira, N. Y. Same machine as in tests Nos. 1 and 2. Discharged 645 gallons per minute through two 500-foot lengths of 2 1-2-inch hose, with one 1 1-8-inch smooth nozzle and one 1 1-4-inch ring nozzle: pump pressure, 225 pounds; suction pressure, 5 pounds;

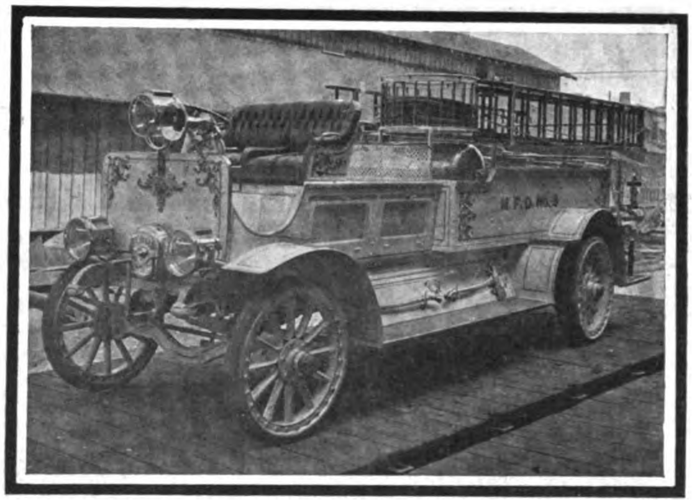


Robinson pump and hose wagon, a compactly arranged combination

Ahrens-Fox pumping engine with pump located in front of radiator



The Martin tractor, for drawing various forms of fire apparatus



The Seagraves combination hose and chemical wagon

net pressure, 230 pounds; nozzle pressure, 79 pounds. Duration of test, 5 minutes.

Test No. 4. American-LaFrance Fire Engine Company, Elmira, N. Y. Same machine as in tests Nos. 1, 2 and 3. Discharged 825 gallons per minute through four 100-foot lines of 2 1-2-inch hose, siamesed into a deluge set with 1 3-4-inch nozzle; pump pressure, 100 pounds; suction pressure, 7 pounds; net pressure, 107 pounds; nozzle pressure, 82 1-2 pounds. Duration of test, 5 minutes.

Test No. 5. American-LaFrance Fire Engine Company, Elmira, N. Y. Four-cylinder motor-pumping car. Horsepower of motor, 70; cylinders, 5 1-2-inch bore, 6-inch stroke. Pump capacity, 450 to 500 gallons per minute. Discharged 264 gallons per minute through 1,000 feet of 2 1-2-inch hose and 1 1-8-inch smooth nozzle; pump pressure, 216 pounds; suction pressure, 5 pounds; net pressure, 221 pounds; nozzle pressure, 49 1-2 pounds. Duration of test, 5 minutes.

Test No. 6. Same machine as test No. 5. Discharged 444 gallons per minute through two 500-foot lines of 2 1-2-inch hose, each with 7-8-inch smooth nozzle; pump pressure, 166 pounds; suction pressure, 6 pounds; net pressure, 172 pounds; nozzle pressure, 96 pounds. Duration of test, 5 minutes.

Test No. 7. American-La-France Fire Engine Company, Elmira, N. Y. Six-cylinder motor pumping car. Horsepower of motor, 100; cylinders, 5 1-2-inch bore and 6-inch stroke. Capacity, 600 to 700 gallons. Discharged 249 gallons per minute through 950 foot of 2 1-2-inch hose and 1 1-8-inch smooth nozzle; pump pressure 188 pounds; suction pressure, 3 pounds; net pressure 191 pounds; nozzle pressure, 44 1-2 pounds. Five minutes.

Test No. 8. Same car as test No. 7. Discharged 425 gallons per minute through two 500-foot lines of 2 1-2-inch hose and 7-8-inch smooth nozzle; pump pressure, 153 pounds; suction pressure, 3 pounds; net pressure, 156 pounds; nozzle pressure, 89 pounds. Duration of test, 5 minutes.

Test No. 9. The Ahrens-Fox Fire Engine Company, Cincinnati, Ohio. Six-cylinder motor pumping car. Horsepower, 72; pump capacity, 400 to 500 gallons per minute. Discharged 244 gallons per minute through 1,000 feet of 2 1-2-inch hose and 1 1-8-inch smooth nozzle; pump pressure, 185 pounds; suction pressure, 5 pounds; net pressure, 190 pounds; nozzle pressure, 42 1-2 pounds. Duration of test, 15 minutes.

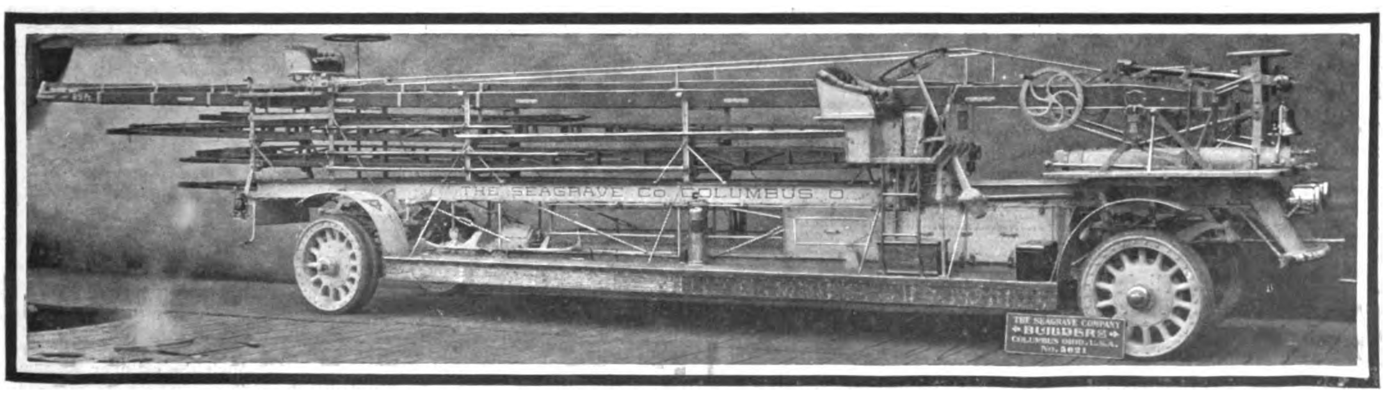
Test No. 10. Same machine as test No. 9. Discharged 340 gallons per minute through two 500-foot lines of 2 1-2-inch hose, with 7-8-inch smooth nozzles; pump pressure, 93 pounds; suction pressure, 4 pounds; net pressure, 97 pounds; nozzle pressure, 56 1-2 pounds. Duration of test, 5 minutes.

Test No. 11. Webb Motor Fire Apparatus Company, St. Louis, Mo. Six-cylinder motor pumping car. Horsepower, 80; pump capacity, 600 gallons per minute. Discharged 246 gallons per minute through 1,000 feet of 2 1-2-inch hose and 1 1-8-inch smooth nozzle; pump pressure, 170 pounds; suction pressure, 3 pounds; net pressure, 173 pounds; nozzle pressure, 43 pounds. Duration of test, 3 minutes. Test of this car discontinued on account of lubricating device not working satisfactorily.

Test No. 12. Same company. Another car, six-cylinder, horsepower, 80. Pump capacity, 600 gallons per minute. Discharged 224 gallons per minute through 1,00 feet of 2 1-2-inch hose and 1 1-8-inch smooth nozzle; pump pressure, 157 pounds; suction pressure, 4 pounds; net pressure, 161 pounds; nozzle pressure, 36 pounds. Duration of test, 5 minutes.

Test No. 13. Same car as test No. 12. Discharged 361 gallons per minute through two 500-foot lines of 2 1-2-inch hose and 7-8-inch nozzle; pump pressure, 113 pounds; suction pressure, 6 pounds; net pressure, 119 pounds; nozzle pressure, 63 1-2 pounds. Duration of test, 7 minutes.

Test No. 14. Same car as tests Nos. 12 and 13. Discharged 589 gallons per minute through two 100-foot lines of 2 1-2-inch hose, siamesed into a deluge set with 1 3-4-inch nozzle; pump pressure, 68 pounds; suction pressure, 9 pounds; net pressure, 77 pounds; nozzle pressure, 42 pounds. Duration of test, 5 minutes.



The Seagraves aerial ladder, with four-wheel drive and steer, one of the interesting exhibits at the Milwaukee show

In the Making of Poppet Valves

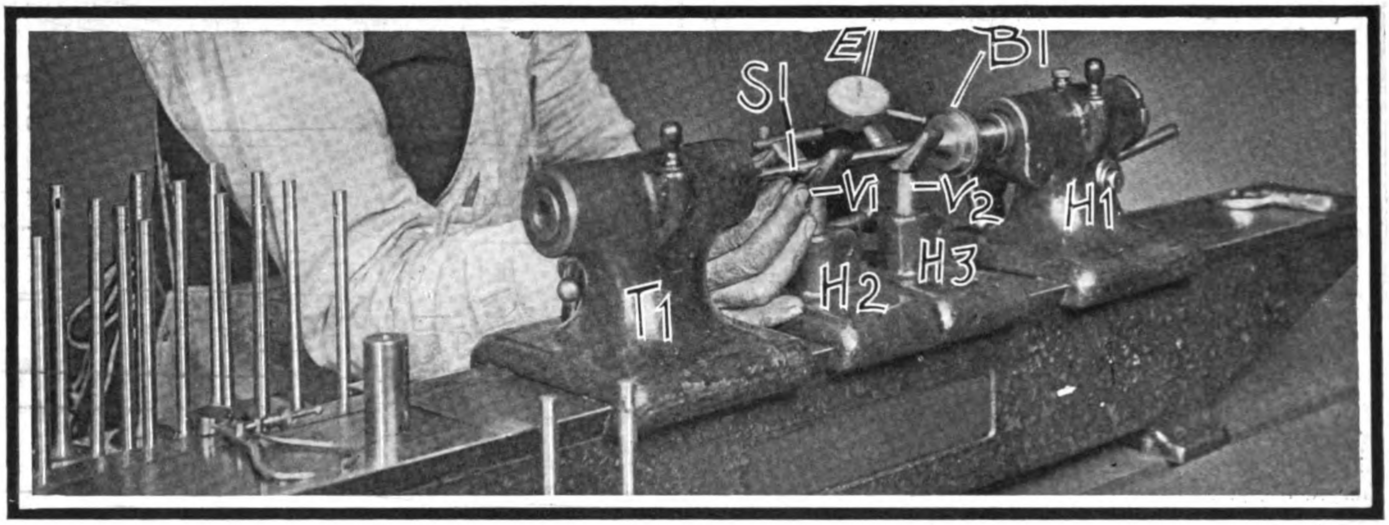


Fig. 1—Method of calibrating valves in order to determine the truth of the seats in relation to the stems

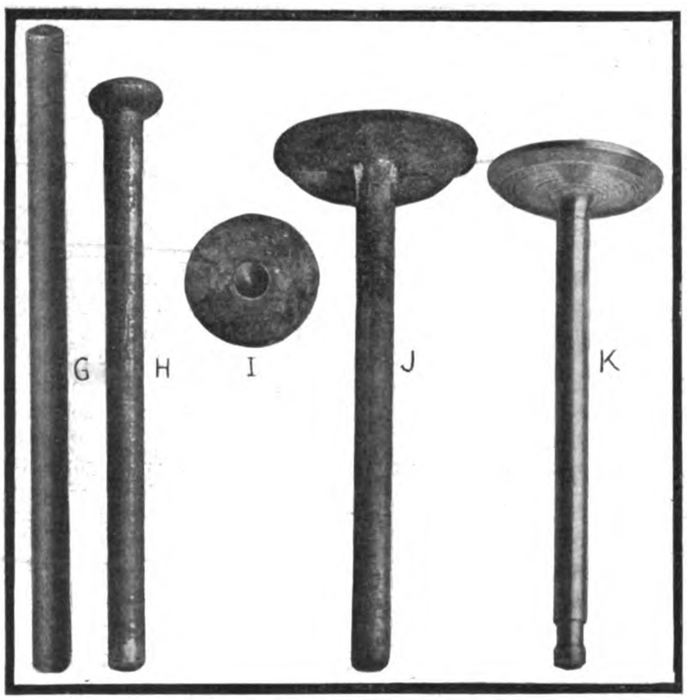

Fig. 2—Components of the built-up valve, showing the various stages of development of valve stems and mushroom welded to it

It is proposed here to show the various stages of manufacture of the poppet valve from the rough material to the finished product. It may surprise some to know that eleven operations are necessary to make a valve, without counting such operations as calibrating and transporting from one machine to the other.

Much has been written of late of different types of valves other than the poppet, which may have created in some people's minds the impression that the death-knell of the poppet valve has been sounded. There does not seem to be any abatement on the part of manufacturers in the use of this type of valve, and one has but to think of the marvelous results that have been achieved with it in the last few years to make it apparent to the veriest tyro that if anything is to come along to supplant it the innovation will have to possess merits out of the ordinary.

A few years ago, when makers were still groping around in the dark without any fixed purpose, except perhaps to make the cars that were turned out run passably well, it was more or less a case of follow-my-leader, and the errors that were made by one manufacturer were copied by the plagiarists of that particular car. It is still within the memory of many that certain cars were taken as prototypes and were copied, lock, stock and barrel. Since the science of building automobiles has developed and the difficulty of making cars run has been overcome, the attention of designers was directed to silencing the road locomotive.

In the earlier days not a little noise emanated from the valve mechanism and this was one of the first things to be attacked in a serious manner. With the poppet valve of the present day, properly made and its operating mechanism carefully designed, there is no reason why noise should be in evidence. The little extra touches of finesse that are added to racing cars deprives them of silently operating valves, as the cams employed for such machines have a different contour from valves used on touring cars. The reason for this is that the valves that control the flow of the gases are in a measure responsible for the amount of gas that is taken into the cylinders; a slow-closing valve which may be quiet will not give the snap to the machine that is the desired quality of a racer. The weight of the reciprocating parts is another point to be considered, but this will be dealt with later. Before dealing with the operation of the valves it will be as well to show how the part is manufactured, taking the various operations seriatim. The finished valve does not look so formidable that it should be requisite to spend

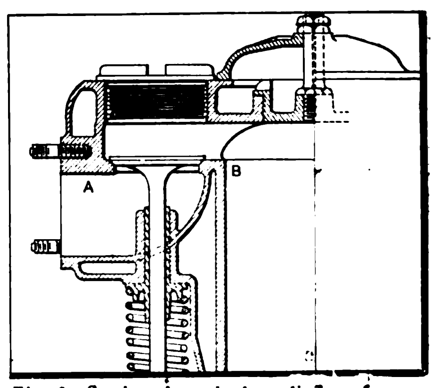

Fig. 3—Section through the cylinder of a motor in which the water-cooling area is bad

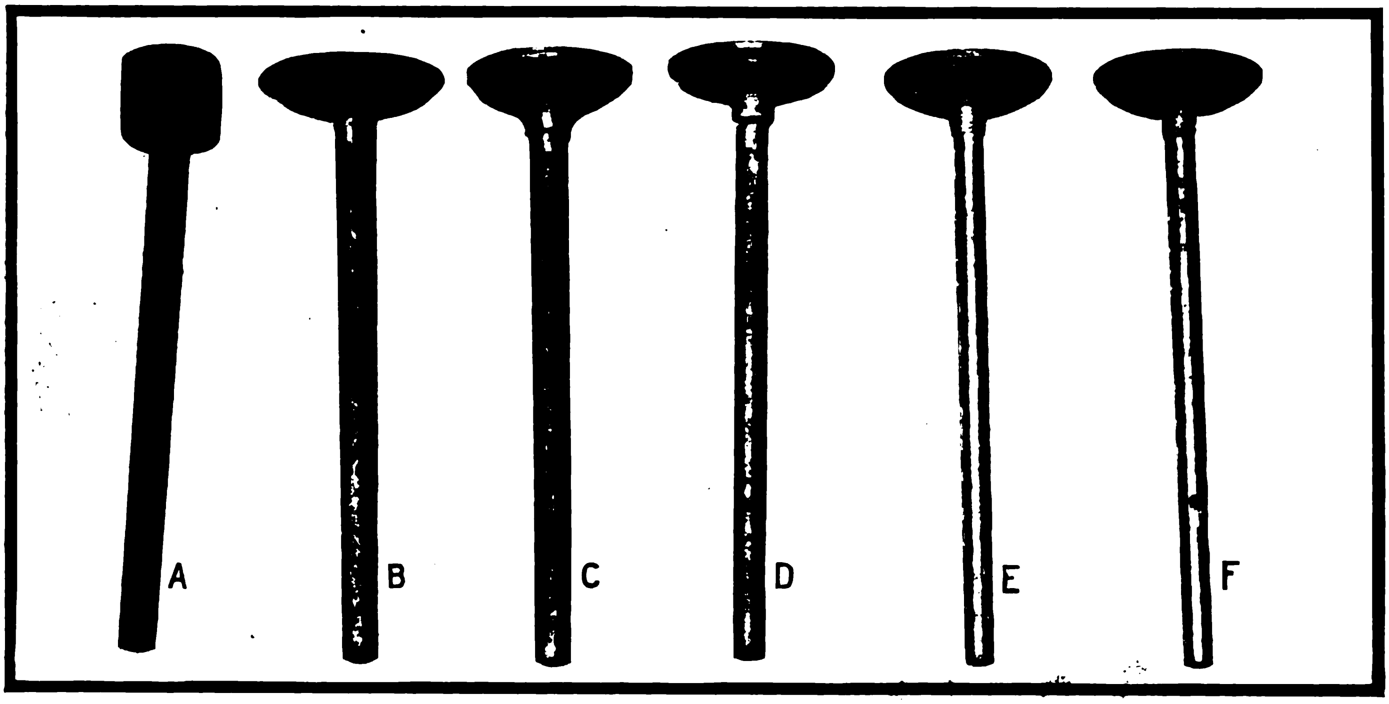

Fig. 4—Showing the appearance of a valve at its different stages of manufacture from the solid rod

much work upon it, but it is not always the part that looks simple that is the easiest to make.

There are two types of poppet valve in vogue at present in gasoline motors. The difference lies in the seat of the valve. The majority of motors have valves with cone seats, but some prefer the flat-seat type. The advantage claimed for the cone type is that it is less liable to pit at the seats, owing to the angularity of the seat being better swept by the flow of the exhaust gases. In case a valve cannot seat there will be a gap on one side and not on the other.

Referring to the question of gap, this may be caused by the deformation of the valve itself, due to improper water-cooling area around the seat. Unless this area is uniform the seat will heat at one point more than another and prevent the valve from properly closing. In the case of the intake valve this may cause a blow-back in the carbureter, but as the heat of the burnt gases passing out of the exhaust passageway materially increases the temperature of the ports the trouble above-mentioned is more likely to obtain in the case of the exhaust valve than with the intake. The consequence would be that owing to the improper seating of the exhaust valve part of the compression would leak past and the motor would not be able to develop its full power. A comparison of two motors in which the difference in the water cooling around the valve is shown in Figs. 3 and 5. In Fig. 3 is shown a solid wall around the valve seat at the point A, while B is bathed by the cooling water. Fig. 5 shows a uniformity at J1 and J2, which will keep the temperature balanced.

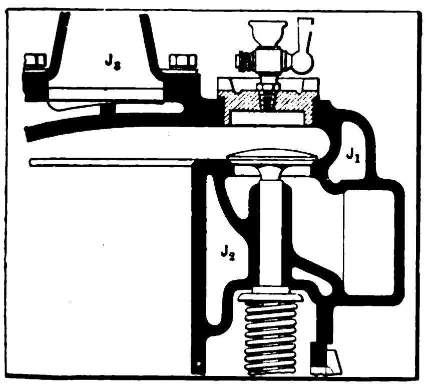

Fig. 5—Section through a valve pocket showing how the entire seat is properly cooled

Besides the methods about to be illustrated there are others that apparently give good results; but those shown being the more commonly employed, it is proposed only to deal with them. In order to differentiate between the two methods of manufacture it may be as well at the outset to designate them as the "stamping" and "building up" processes. Dealing with the stamping process, if reference be made to Fig. 4, the different forms that the valve takes during the various stages of manufacture will be seen. A shows the first stage in which a piece of rod is drawn on the hammer in order to form the stem. This operation is very simple and does not need any particular care, with the exception that the metal should not be overheated. The same applies to the next process, when the part as shown at A is heated before being placed in the die, shown in Fig. 9. In this illustration the head of the red-hot valve (V1) may be seen in the die (D1). The weight is allowed to drop twice, the upper half of the die (D2) battering the metal and forming the mushroom. The appearance of the valve as it leaves the

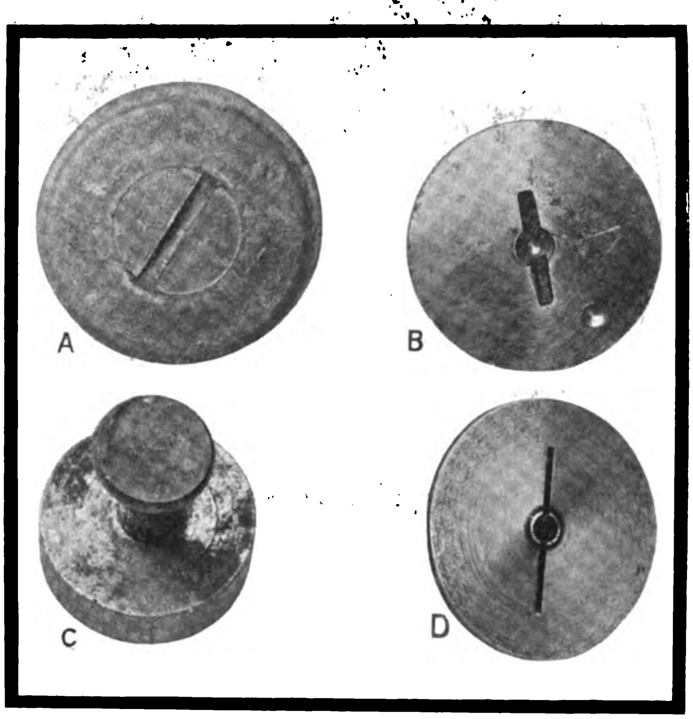

Fig. 6—A and B show the rough and finished valve stamped from one piece; C shows the metal before stamping, and D the finished valve

steam hammer is shown at B, in Fig. 4, and in order to save one operation, viz., that of slotting the head of the valve to receive a screwdriver to facilitate grinding, the upper part of the die has a protrusion which slots the head of the valve in a manner similar to that shown at A in Fig. 6. The head of the valve at B in this illustration shows the manner in which it is centered for the various machines into which it has to be inserted, as well as a small hole for the pointer which holds it in position and prevents it from slipping while being turned.

The head is then ground and the seat cut rough on the lathe, the correct contour being given to the fillet, as shown at C in Fig. 4. The next operation consists in placing the valve in the lathe in the manner shown in Fig. 8 in order to turn up the stem to the required thickness. The valve is centered in the chuck (C) and the tool (T) held in the tool-holder (H). When the valve leaves the lathe it is practically in the rough—that is to say, unfinished. It is possible by using other cutters to finish the valve so that it would be ready to place in a motor, but the present-day methods of grinding are preferred by most manufacturers.

The valves are next transported to a machine where boys drill three holes in the stem of each valve preparatory to the

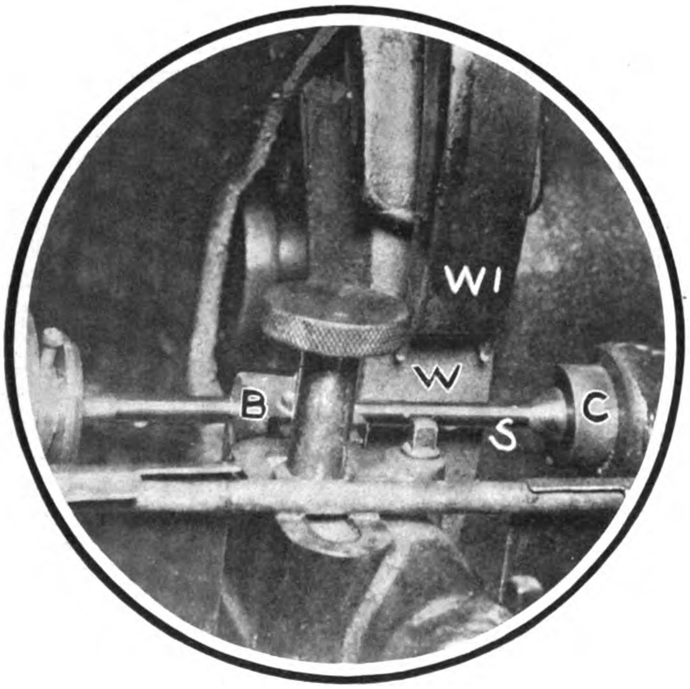

Fig. 7—Showing the grinding operation for the stems of valves

operation of cutting the slots for the cotter pins. The latter operation is shown in Fig. 11. The valve (V) is placed in the receptacle in the plate (P), which has a slot cut therein at S. The chuck (D) of the hammer is furnished with a slotting tool (C) held in position by the setscrew (S1). As the weight falls the slotting tool cuts the metal between the holes that have been previously drilled, but the blow is apt to slightly bend the stem of the valve.

It is a simple matter to rectify this and the operation of straightening the stem is shown in Fig. 10. The operator is furnished with a tool that has two centers into which the valve is placed and sufficient tightness is furnished by the milled nut (N) to hold the valve in position. The valve laying alongside the machine shows the amount of disalignment that has to be corrected. The operator spins the valve and with the aid of a piece of chalk (C), held in his left hand, the high spot can be located. Usually a single blow with the hammer (H) at this point will be sufficient to correct this, but it may require several blows before the valve is again true. The operation does not call for a great amount of skill, consequently un-

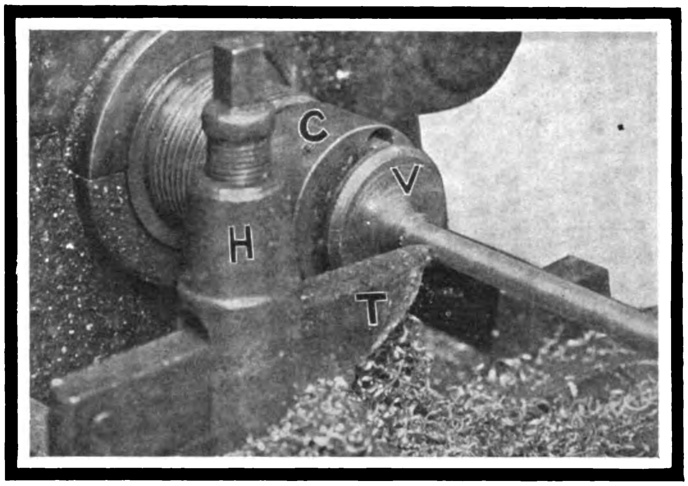

Fig. 8—Method of rough turning the valve after having both ends centered

skilled labor is employed for this work with satisfactory results.

The next operation, that of grinding the valve stem (Fig. 7), may be performed in the same machine that is used for grinding the seat, but at the Maxwell plant, where the illustrations of the stamping process were made, the operation is carried out in two stages. The valve head is placed in the lathe center (C) and a lathe carrier causes the valve to rotate. In order to avoid any whip in the spindle when the pressure of the grinding wheel (W) is brought to bear upon it a split block (B) forms a rest for the spindle. The valve stem rotates in a clockwise direction, while the grinding wheel (W) revolves in an anti-clock wise sense, a steady stream of water being meanwhile fed through the pipe (W1) to the part being ground. The valve, after the stem has been ground, is shown at E, in Fig. 4. The last operation in the manufacture is illustrated in Fig. 12, in which the valve (S1) is centered in the head of

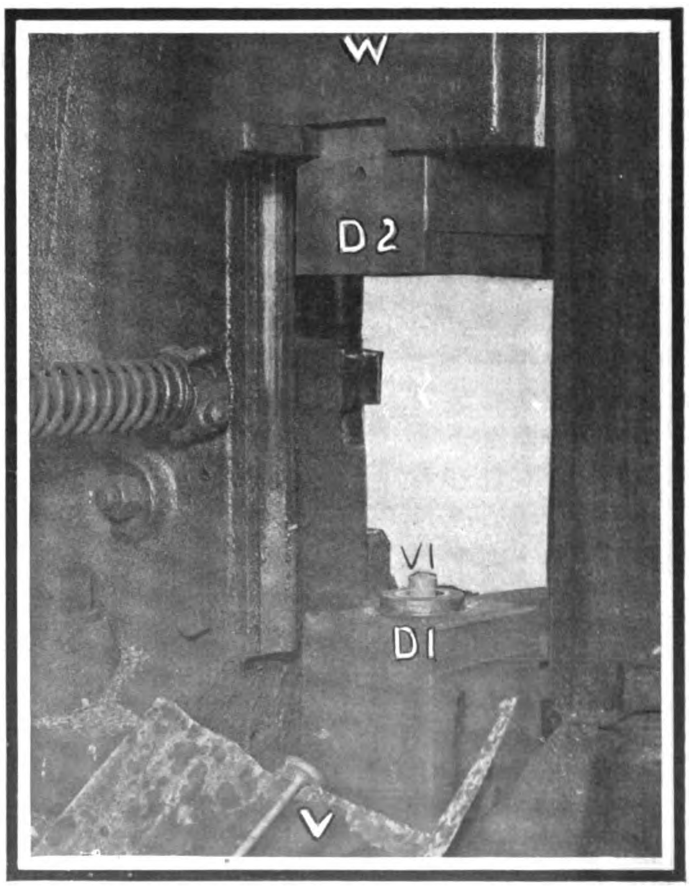

Fig. 9—Showing the hammer with the valve in position ready to be stamped

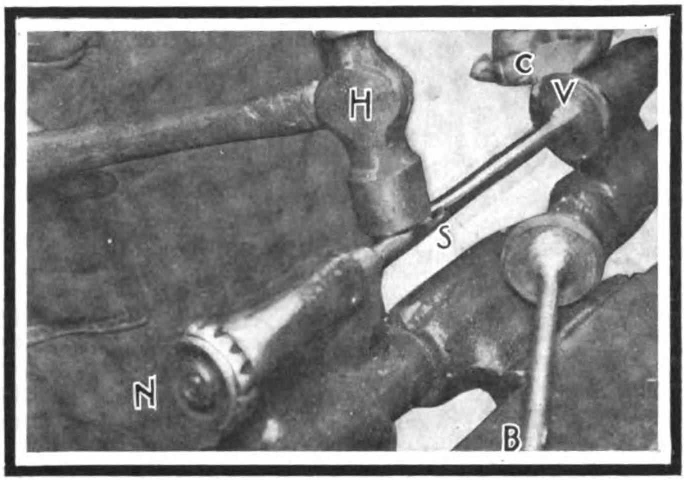

Fig. 10—Truing up the stem of a valve after cotter pin slot is stamped

the lathe (C) and attached to the chuck (C1). The valve is caused to rotate in the opposite direction to the grinding wheel (W) and water is fed, as in the stem grinding operation, through the pipe (W1). The finished valve is shown at F, in Fig. 4.

The method of building up the valve from two parts instead of stamping it from the solid, as already described, may be seen very clearly by referring to Fig. 2. In the case of the stamped valve it is of a necessity that the entire valve be of the same material, whereas in the built-up valve a different material may be used for the seat to the stem. In the illustration referred to the process is as follows: The stick of .15 carbon steel G is compressed at the top extremity so as to present a form similar to H, in Fig. 2. A disc I, 11-16 of an inch thick and 1 3-4 inches in diameter, is cut from .05 nickel steel stock, drilled with a 1-2-inch hole and placed over the stem in the manner shown at C, in Fig. 6. The assembly is then heated and placed in a die in a manner similar to that shown in Fig. 9, and the two parts are thus welded together. The form that they take is shown at J, in Fig. 2. The thickness of the head after welding is reduced to 7-16 of an inch, and the width increased to 2 3-4 inches. The finished valve is shown at K, in which the thickness of the head, after turning, is 9-32 of an inch and the diameter of the upper face 2 15-16 inches. D, in Fig. 6, shows the head of the valve after being turned and slotted. The illustrations of the assembly process were taken at the Mercer plant, and it will be noticed in K, in Fig. 2, that the base of the stem is slightly smaller in diameter in order to accommodate a split ring for holding the valve spring in place.

Fig. 1 shows a process sometimes resorted to in order to determine whether the stem and seat are absolutely concentric. The valve is chucked and rests lightly on the holders (H2 and H3), and by rotating the valve by hand, it is possible to read on the dial of the instrument (E1) the most minute fault in the manufacture. A valve may seat quite well on one of the valve seats, but as all valves at the present day are being made interchangeable, it is necessary that all shall be alike.

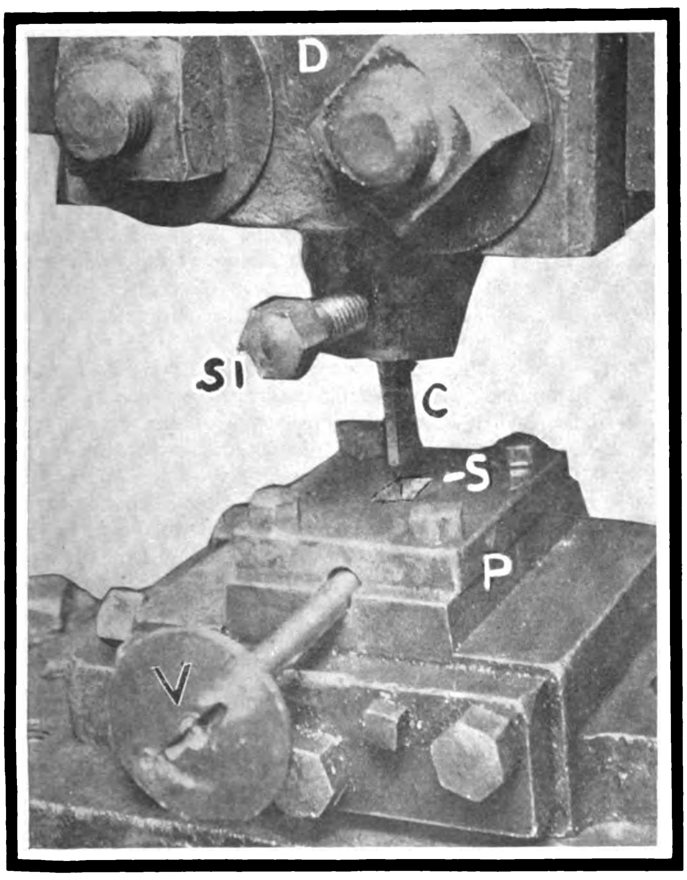

Fig. 11—Slotting machine with which the slots in the valve stem are cut

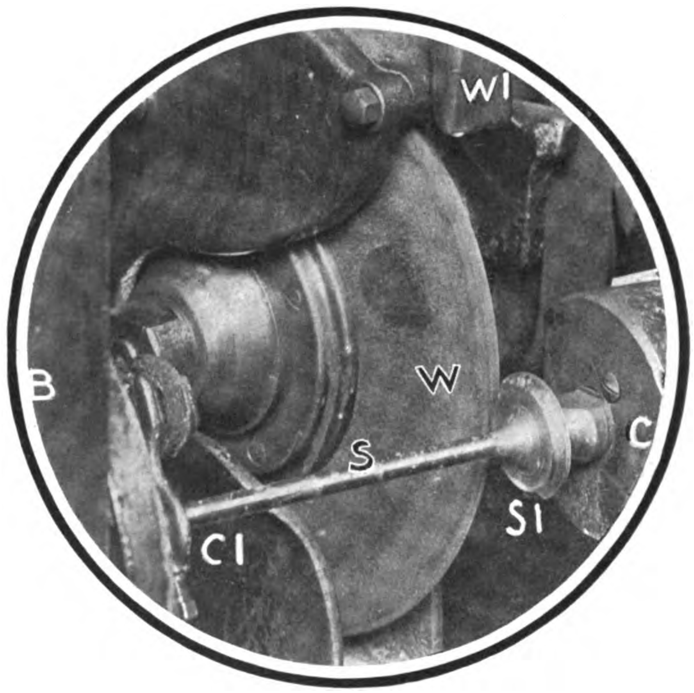

Fig. 12—Grinding the seats of valves, thereby giving a true surface

Steel Should Be Tested for Nitrogen

Steel of unknown origin should be tested for nitrogen rather than for phosphorus. The popularly accepted idea that phosphorus and an excess of sulphur cause brittleness—an idea which finds expression in most specifications for steel materials—should be corrected as promptly as possible by placing under ban nitrogen first of all, as this substance may be found in all kinds of steel while phosphorus and sulphur are unlikely to exceed 0.06 per cent. in either acid or basic open-hearth steel. That nitrogen is the impurity to which the comparative brittleness of Bessemer steel is mainly due was first pointed out by Braune, a Swedish chemist living in Paris, but while it is always present in unrefined Bessemer steel it may be found in open-hearth steel as well. Nitrogen in excess of 0.06 per cent. should never be admitted for boiler plate, for example. (The boiler explosions in the French navy have made this subject one of national importance in France.) The author has repeatedly argued the question of the cause of brittleness in steel before the British Iron and Steel Institute since 1885.—C. E. Stromeyer in *La Technique Automobile et Aérienne*, February and March.

Stresses and Strains in Tires

Part III.

Translation of an article by Henri Petit from La Technique Automobil et Aérienne

THIS high coefficient of security shows that a tire cannot burst under normal conditions through an additional excess of pressure.

The tension of the canvas being always proportional to the internal pressure it can be seen even in the most unfavorable case, viz.: that of a 135 m.m. tire that it would be necessary to raise the internal pressure to 56 kilos to arrive at a tearing point of the canvas. In practice the tire will probably burst before this limit is reached, owing largely to the inevitable imperfections of manufacture due to the unequal tension of the canvas.

But the fact remains, however, that practical tests that have been carried out by the simple means of increasing the internal pressure in order to burst a tire have been without result; in nearly all cases the rims become deformed, allowing the beads of the tire to fly out before the tire shows signs of weakness.

The fears possessed by certain chauffeurs of having their tires burst in the sun are mere myths, in most cases. The amplification "most cases" is used because it is evident that if a tire is old and the canvas has been subjected to the action of the humidity to the point of becoming rotten (which is a state that exists more often than one would think, for although the tire looks to be in good condition) a burst can very easily take place.

Action of the Temperature

It is interesting to note the influence of the temperature on the internal pressure in tires. Suppose a tire to be inflated at 0° to a regular pressure of 10 kilogs. During the course of the day, under the simultaneous action of the sun and especially the speed and weight of the car, the imprisoned air can attain a temperature of 80° Centigrade, consequently producing an increase of pressure.

The pressure p attained at this moment will equal:

$$p = p^\circ (1 + \alpha t)$$

that is to say,

$$p = p^\circ \left[1 + \frac{80}{273} \right]$$

$$= p^\circ \times 1.3 \text{ about.}$$

The pressure will only rise in the third of the primary value. The proportional increase of the tension on the canvas for a tire in good condition is more or less a negligible quantity.

Further, when one talks of the causes of deterioration of tires it will be seen that the action of the heat on the rubber is more important than on the internal pressure.

Action of Weight on Tension of Canvas

All that has previously been stated refers to a tire simply inflated and not carrying any weight.

There is nothing to be modified in the conclusions drawn if one only passes to a practical case where the tire rests upon the ground and carries a weight P. (It will be remembered that we are only interested at the moment in static efforts—that is to say, the case when the tire is stationary.)

Under the influence of the charge the tire will flatten out until the force exerted by the internal pressure on the surface of contact equilibrates the weight supported.

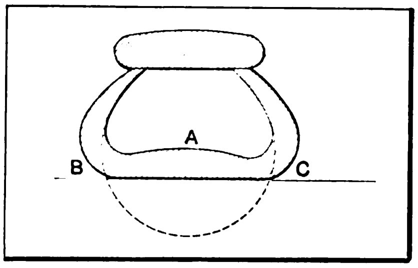

Fig. 4—Showing change in form of meridian section of insufficiently inflated tire

Allowing for the stiffness of the canvas it can be seen that we will have the equation

$$ps = P$$

calling s the surface of contact of the tread with the ground and measured in square centimeters.

This contact area is not in the form of a well-defined geometrical form. It can be likened to an ellipse, the greater axis of which lies in the lateral plane of the wheel. This ellipse will be proportionally lengthened according to the narrowness of the tire and the increase in diameter of the wheel.

It can be seen that the work necessary for the propulsion of the car is dependent on the form of this surface, and is greater according to the relation of the large and smaller axis being smaller.

The flattening of the tire produces a depression in the interior of the casing and the volume thereof diminishes slightly due to this flattening. The increase in pressure is quite insignificant and need not be considered. The point which must be borne in mind, however, is the change in the form of the meridian section of the tire at the point of contact with the ground. Fig. 4 shows in an exaggerated form what takes place.

If the tire were very narrow or, on the other hand, formed of a single layer of canvas this deformation would not be of great importance. But as the various layers of canvas present a considerable thickness, it follows that to pass from the normal form to the form represented in Fig. 4 the layers of canvas will slide on one another. This displacement is possible owing to the layer of rubber compound interposed between each layer; the rubber stretches at the points extended and contracts at the others, permitting a small relative displacement.

It is clear that this sliding should be as small as possible; the tensions that are developed between the layers of canvas and their coating of rubber develop, as a matter of fact, values proportionately greater as the displacement increases, tensions which could in time cause the rubber to become detached from the canvas.

On the other hand, on account of the hysteresis that accompanies all physical phenomena, in the present case the deformations of the rubber, during the movements of the revolutions of the wheel successive deformations of the diverse sections are accompanied with a considerable production of heat.

In a large measure it is due to this that a tire that is insufficiently inflated (or overcharged, which comes to the same thing in the case under notice) heats more than the same tire submitted to the same charge, but inflated to a greater degree. Another cause of heating lies in the friction of the tire with the ground; this will be dealt with later.

Method of Attachment

The tire is held in position in the rim by the pressure of the air on the beads.

It is interesting to form an idea of the greatness of the force that holds the tire in position. The tire in the vicinity of the sides of the bead is submitted to the action of two forces: the one Φ (superficial tension) tends to draw the bead outward, the other F (arising from the internal pressure) has on the contrary action of forcing the bead into the base of the rim (Fig. 5).

On account of the form of this latter, it is possible for the bead to turn around the point A (allowing for the resistance of the canvas). Then the force Φ is applied at the middle of the thickness e of the tire at this point. Its moment in relation to the fixed point A is equivalent to

$$\frac{\Phi \times e}{2}$$

The force F is applied at the middle of the interior width of the bead. It is normally at the surface. Its moment in relation to A is

$$\frac{F\,l}{2}$$

In order that the bead should be maintained in position, one must have

$$F\,l > \Phi\, e$$

For the unity of the length of the tire the force F is equal to:

$$p \times l$$

The force Φ is the maximum meridian tension of the tire. It is expressed by

$$T_M = \frac{R\,r}{R - r}\,p$$

From which

$$p\,l^2 > p\,e\,\frac{R\,r}{R - r}$$

The resultant couple, which we will call the couple of security, will be equal to the difference of the components

$$C = \frac{p}{2}\left[l^2 - e\,\frac{R\,r}{R - r}\right]$$

It should be positive and have as large a value as possible.

Let us calculate this value for current dimensions of tires (90, 120, 135).

The value of C can be written

$$C = \frac{p}{2}\left[l^2 - e\,\frac{R}{\dfrac{R}{r} - 1}\right]$$

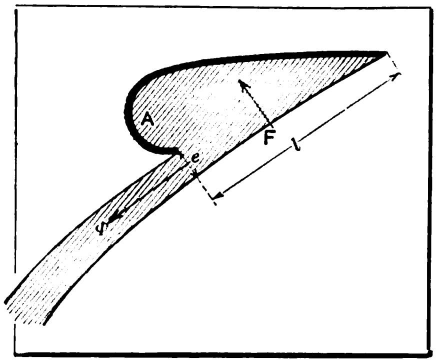

Fig. 5—Showing forces acting on bead of tire

From the foregoing it becomes at once apparent that C will be proportionately smaller as $\frac{R}{r}$ decreases in size.

The values of $\frac{R}{r}$ are given in the table earlier in the article.

The minimum values are:

7 for tires 700×90
6 for tires 820×120
5.5 for tires 895×135

It will be remembered that for each section $\frac{R}{r}$ is proportionately smaller as the size of the wheel is smaller.

The corresponding value of $\dfrac{R}{\dfrac{R}{r} - 1}$ are respectively

3.5 6.3 8.5

The thickness e is approximately equal to 1 millimeter per layer of canvas as:

6 millimeters for a tire of 90 m.m. section.
8 " " " 120 " "
9 " " " 135 " "

But for a 90 m.m. section tire the width of the bead is about 23 millimeters.

From which for C

$$C = \frac{p}{2}\left[2.3^2 - 0.6 \times 3.5\right]$$

$$= p \times 1.6$$

8 kilo-centimeter per centimeter.

It is necessary, therefore, that the width of the beads increase with the tire width.

To obtain a like value for C with a tire 895×135 (taking into consideration the internal pressures) it is necessary to make the beads 33 millimeters wide.

These figures, though seeming to be void of interest in themselves, nevertheless should be borne in mind.

Harking Back a Decade

THE *Motor Review* of September 26, 1901, contained the following items indicating the growth of the new automobile industry:

Announcement is made that an American factory for the Charron was to be installed with a capacity for the 1902 season of 100 cars a month.

The Washington Auto-Vehicle Company was incorporated for $1,000,000 to manufacture pleasure cars and parts, and it was announced that in the future the company would take up the manufacture of army automobiles, fire apparatus and cars for various kinds of municipal and government work.

It is noted that Ray MacDonald and Howard Freeman, former bicycle stars, had taken jobs as chauffeurs with the Automobile Company of America.

A. J. Eddy, of Chicago, who completed a trip from his home to Boston and New York in a single-cylinder Winton, two weeks before the publication date, expressed himself as being confident that American automobiles were better for cross-country touring than foreign machines.

Exports of automobiles and parts from the United States for the week ending September 18, 1901, amounted to $24,000. During July, 1901, the automobile exports were valued at $72,000.

Announcement was made that W. D. Gash, of the Waltham Manufacturing Company, had been made sales manager for the Searchmont Motor Company.

W. B. Felker, of Denver, recounted his experience in climbing Pike's Peak, using the abandoned wagon road up that mountain. The round trip required over fifteen hours, using his steam Locomobile. At that time the climb represented a new altitude record for the automobile.

Great preparations were being made for the Fort Erie race meeting, which project had been revived after being called off on account of McKinley's assassination. The Automobile Club of Buffalo hung up silver cups for the winners in the various classes, for which twenty-one entries were made.

The Consumers' New York Rubber Tire Company, incorporated by W. H. Seaich, John W. Horner, Alfred D. Moulton, Hooper C. Barrett and Andrew C. Farnsworth, was announced.

The leading patent outlined in that week's issue was No. 682,-194, granted to Henry K. Hess, of Philadelphia, on a steam automobile using charcoal or other carboniferous fuel in solid form instead of liquid hydrocarbon.

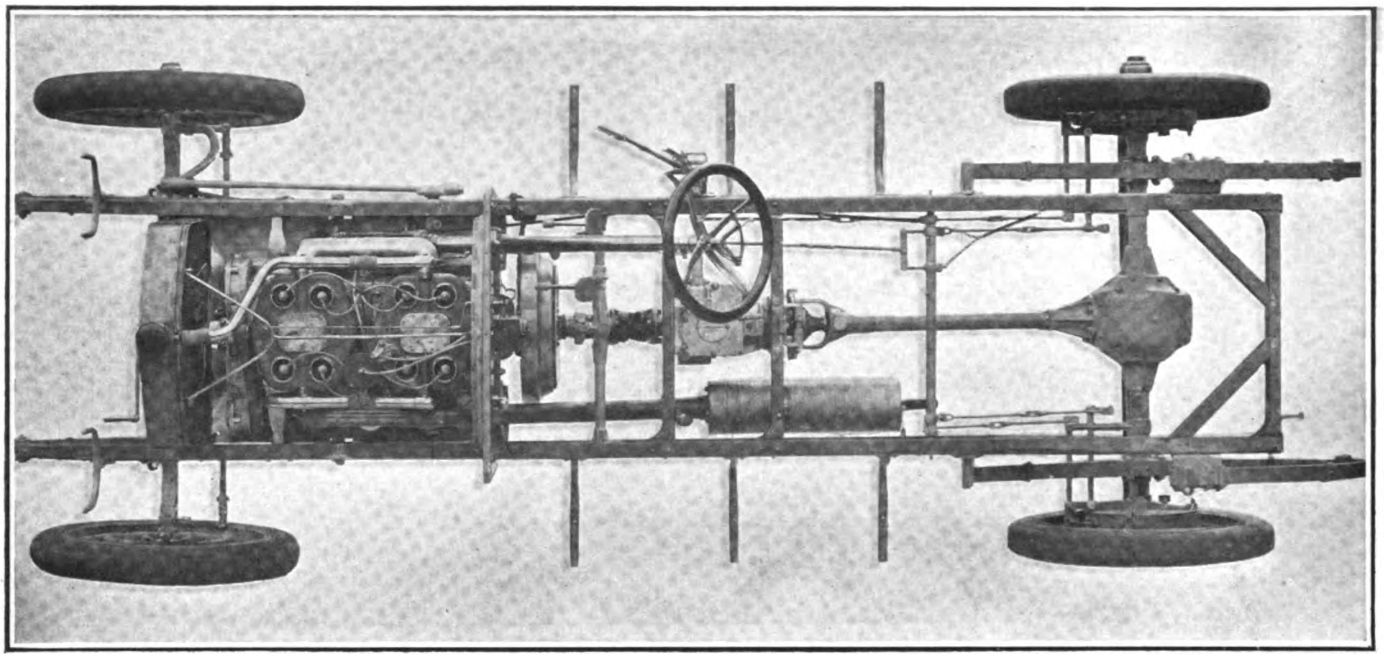

Fig. 1—Looking down on the National chassis, showing power plant, suspension and assembly of units

Details of National Construction

NO marked changes characterize the new season's models of the National Motor Vehicle Company, of Indianapolis, Ind. The new models will be known as the National "40," Series S, and a numerical suffix will be used to designate the particular style of body. The changes that will be made will be along the line of refinements, in view of a year's experience, both on the road and in the racing field. Improvements in manufacturing operations designed to eliminate wear and noise have been carefully studied and nothing has been left undone to render the car satisfactory in every way.

The general appearance of the chassis may be seen from the plan view shown in Fig. 1, which discloses a four-cylinder motor attached to the main frame, cone clutch, three-speed transmission, and live rear axle drive. The method of operating the brakes is also shown in this illustration.

The motor has four cylinders, cast in pairs, and thoroughly annealed, the bore being 5 inches and the piston travel 5 11/16 inches. Fig. 5 shows a front transverse section through one-half of a cylinder together with the base chamber. The cylinders are cast with T-heads and the intake and exhaust valves, which are made of nickel steel, are placed on opposite sides. The valve V has a cone seat S1 and reciprocates in a bushing B which is inserted into the cylinder casting. The cam operation may be seen by referring to the cam C1, upon which a roller R rides. The push-rod P1 is fitted at its upper extremity with adjusting nuts N, and the roller R is held in constant contact with the cam C1 by means of a spring S2.

The method of attaching the exhaust manifold E and the water manifold W is unique. The yoke Y has a forked end F and a single arm A so that when the nut N1 is tightened upon the stud S both manifolds are maintained firmly attached to the cylinders, thereby eliminating a large number of connections.

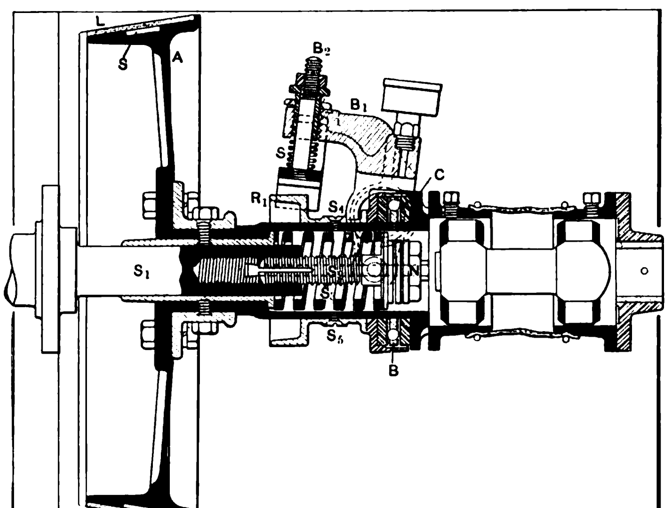

Fig. 2—Detailed view of the National cone-type clutch and universal joint

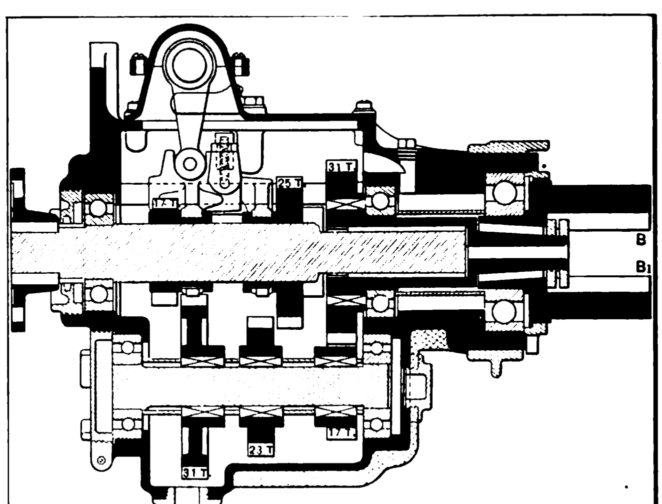

Fig. 3—Horizontal section through the three-speed and reverse selective transmission

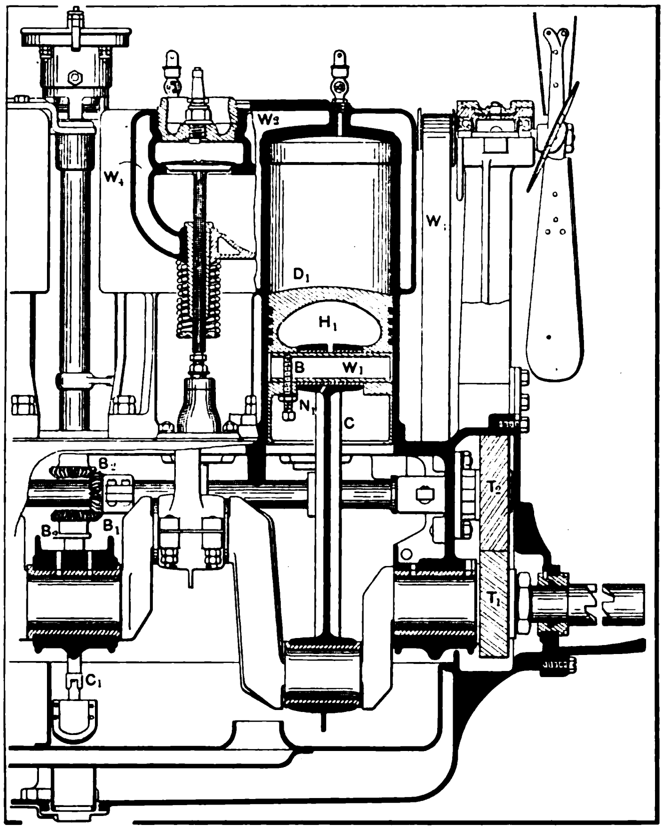

Fig. 4—Plan section of National motor, showing oiling, ignition and cooling systems

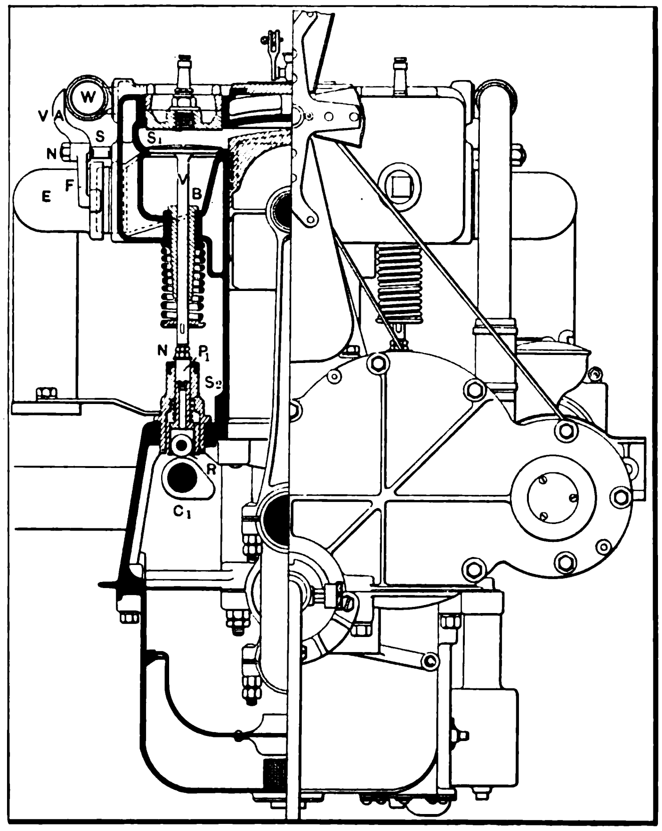

Fig. 5—Front transverse section through an engine cylinder and part of the base-chamber

The plan section of the motor, Fig. 4, discloses the method of operating the oil pump and distributor by means of bevel gearing B1, B2 and B3. The pistons have a slight dished top D1 and the wrist pins W1 are hollow. The method of mounting the piston wrist pin and connecting rod is shown in this illustration, and it will be seen that the wrist pin and piston are united by means of the bolt B and locked in position by the nut N1. This allows the connecting rod C to oscillate upon the wrist pin W1 and the small end of the connecting rod has a hole drilled above in order to permit the lubricant to enter. The oil pump being driven by the shaft attached to the bevel gear G2 can be removed from the lower half of the base chamber without disturbing the position of the above-mentioned gear wheel, as there is a tongue joint C1 interposed between the pump shaft and the operating shaft.

The water jacketing of the motor is shown at W2, W3 and W4, which illustrates the manner in which the cylinder is cooled to the point where the heated gases obtain.

The timing gears T1 and T2 are skew-cut, a practice which has been found to eliminate a considerable amount of noise from these parts. The crankshaft is mounted on three main bearings, made of Parsons white bronze.

Fig. 6 shows the exterior view of the motor. From this it will be seen that the support S1 by means of which the motor is attached to the frame at its forward extremity is bolted to the upper half of the aluminum base chamber instead

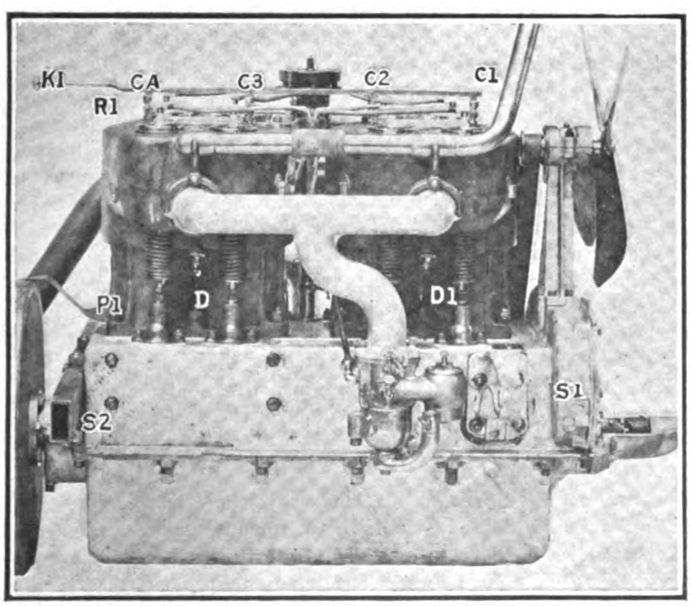

Fig. 6—Intake side of motor, showing substantial supporting members, carbureter and cocks to drain water from jackets

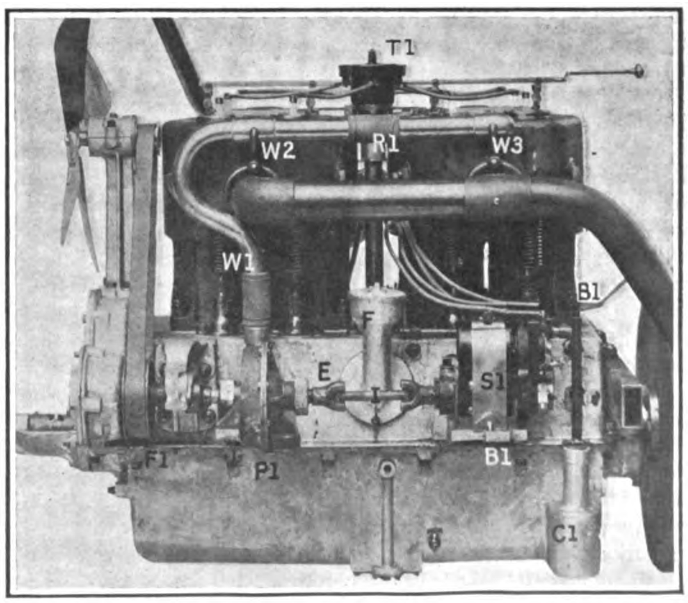

Fig. 7—View of the exhaust side of the motor, showing magneto, water pump, oil filler hole and cork-float indicator housing

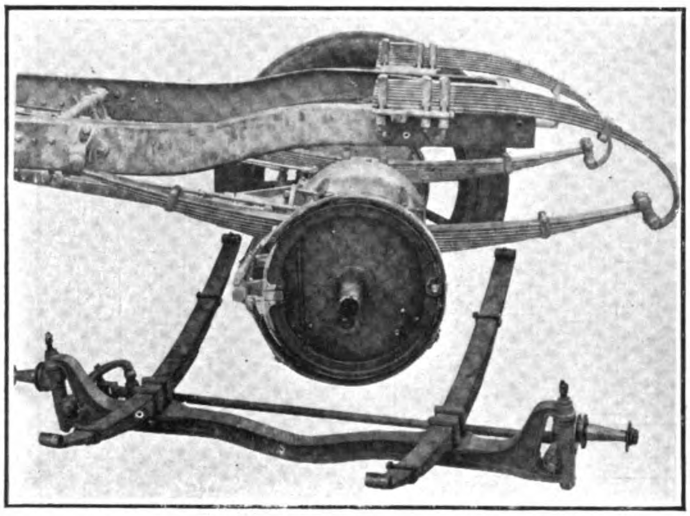

Fig. 8—Showing suspension of National front and rear axle, as well as brake construction and differential in perspective

of being cast integral therewith and the rear support S2 is attached to the motor by means of long through bolts. Drain-cocks D and D1 are provided, thus rendering it possible to drain off the water entirely from the cylinders. The compression cocks C1, C2, C3 and C4 are placed in the heads of the cylinder and can be operated by the knob K1, which passes through the dashboard and is attached to the rod R1, which in turn is attached to the arms of the cocks. In order to facilitate the timing of the motor a pointer P1 is provided and the flywheel is marked with the various settings for the valves and the ignition.

The exhaust side of the motor is shown in Fig. 7, in which the timer T1 can be seen. The fan pulley F1 and water pump P1 are driven by gearing from the half-time shaft, and the water is conveyed from the pump, which is of the centrifugal type, to the pipe W1 and enters the cylinders at the points W2 and W3, a piece of rubber tubing R1 being placed between the two pipes to take care of any vibration. Tapered nipples are used on the intake, exhaust and water pipes, thereby doing away with all packing joints.

The pump shaft carries an extension E which drives the intermediate shaft I, which in turn drives the magneto. By undoing the strap S1 it is possible to remove the magneto from its base B1 and all alignment between magneto and pump is taken care of by the shaft I. Oil is poured in the base chamber through the large filler F, a cork float within the housing C1 serving to indicate when the correct level has been attained by means of a small ball which is attached to the float.

Two sets of spark plugs, located in the valve caps, are provided, and besides the magneto ignition a separate and independent ignition is provided by means of storage battery, single vibrator coil and distributor. Either or both systems may be used at will. A double distributor, Splitdorf magneto, with two sets of plugs and storage battery is used on the roadster model, and this system fires both sets of plugs simultaneously, either battery or magneto. The carbureter is of the float feed type, with a 1¾-inch connection on all models, except the roadster, which has a 2-inch connection. A metal strap attached to the base chamber holds the body of the carbureter rigid.

Oil is taken from the base by a pump and delivered to the sight feed on the dash, whence the oil is returned to the main bearings. A false bottom is fitted inside the base, forming troughs for the connecting rod scoops to dip into. A continual flow occasioned by the pump fills these troughs to a level sufficient to insure proper lubrication and prevent over-lubrication. When the level of the oil becomes higher than the standpipes it overflows and returns to the sump. The pistons and cylinders are lubricated by the splash of the connecting rods and above the main bearings cups are provided to maintain a constant flow of oil to these parts.

The clutch is a cone type and is shown in detail in Fig. 2. The aluminum member A is faced with a leather covering L, beneath which six flat springs are provided. These cause the leather to bulge at six points, thereby insuring an easy engagement. The spigot S1 is drilled and tapped and accommodates the bolt S2; the spring S3 is held in tension by the locking nut N, and disengagement is brought about by causing the collar C1 to recede. A ball thrust B is provided to take care of the thrust during the disengagement. Attached to the disengaging arm there is a bracket B1 which is fitted with a through bolt B2, the lower extremity of which is provided with a leather-faced surface. As the disengagement arm is operated by the clutch pedal the bracket B is caused to descend and to come into contact with the ring R1, which is attached to the main body of the clutch by set-screws S4 and S5, thus preventing continued spinning of the clutch when disengaged and facilitating changing from one speed to another. The spring S prevents any gripping action of the clutch brake.

The transmission is of the selective type, giving three speeds forward and reverse. The shafts, as may be seen from Fig. 8, are carried upon annular ball bearings, and packing glands are provided so that oil can be used for lubrication instead of grease. A universal joint, shown in Fig. 2, is placed between the clutch and transmission, taking care of any disalignment that may be occasioned by the bending of the chassis frame, due to inequalities of the road surface as well as slight faults of assembly. The gear is supported upon two cross members of the chassis frame, as may be seen by referring to Fig. 1.

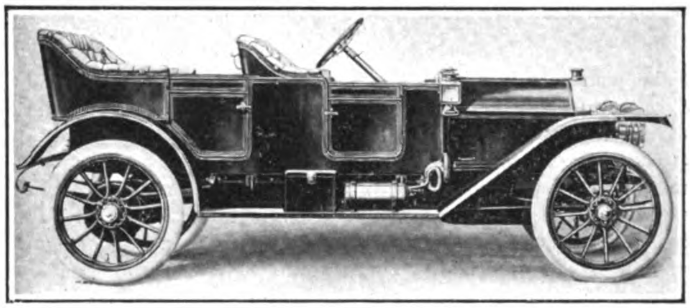

Fig. 9—Side view of seven-passenger, fore-door type of touring car and neat arrangement of accessories on footboard

Power is transmitted from the gearbox to the live rear axle by a 1⅜-inch propeller shaft enclosed in a casing extending from the rear axle housing to a forked joint at the forward extremity. This fork is hinged upon a bracket attached to a cross member of the frame, and the torque is taken up therein. A section of the live rear axle, which is of the full floating type, is shown in Fig. 11, from which it will be seen that roller bearings are employed throughout. This illustration also shows the method employed for operating the brakes, acting upon the rear wheel drums. By removing the cover over the rear axle it is possible to remove the differential parts.

The suspension in the National is taken care of by means of semi-elliptic springs at the front, attached to an I-beam axle, as shown in Fig. 8; the rear suspension, however, is of the three-quarter elliptic type and the method of attaching the springs to the chassis frame is shown in the same illustration.

The wheels are fitted with 36 x 4-inch tires, but the buyer has the option of choosing 34 x 4 1-2-inch on the speedway roadster and 37 x 4 1-2-inch upon the touring cars and the limousines.

MANY of the Sheffield, England, physicians have abandoned their horses and carriages and gone in for automobiling for practical use. Fifty per cent. of the cars in use in Sheffield are of the high-power touring type. The same rule prevails throughout the United Kingdom.

To Fit Car to Buyer

(Extract from a paper read before the British Institute of Carriage Manufacturers in London, Sept. 4, 1911, by Mr. Herbert Austin.)

IF at the commencement of the automobile era it had been possible to realise the extent of its use to-day, and of the demand for speed and luxury, closer attention would no doubt have been paid to the creation of a vehicle designed to meet the entirely different conditions caused by the advent of the new means of locomotion. This evolution is going on every day, and perhaps the gradual change is for the best, as had it been too sudden the public might have objected more strongly than it did, and the conditions appertaining to the use of the automobile would have been so much more difficult to cope with.

The demand to-day is for seats to be low, and they must, therefore, be sloped downwards toward the back. This means taking up more room lengthwise on the chassis, and unless the accommodation at the back can be curtailed the body must overhang more or the chassis will have to be lengthened to conform with the requirements.

To be able to provide for variations in the dimensions of drivers and the positions they wish to be fitted, an adjustable seat has been designed by the author. This seat can be placed in any position that could possibly be required, and attached to it is a steering column and pedals. All the holes for adjustment are marked so that a record can be taken of the position most convenient to the customer and enabling the manufacturer to copy the dimensions found in the car delivered to the buyer.

Of course, the positions allowable with a standard body are limited, and these limits are noted on each design. Some provision would have to be made in the steering column and

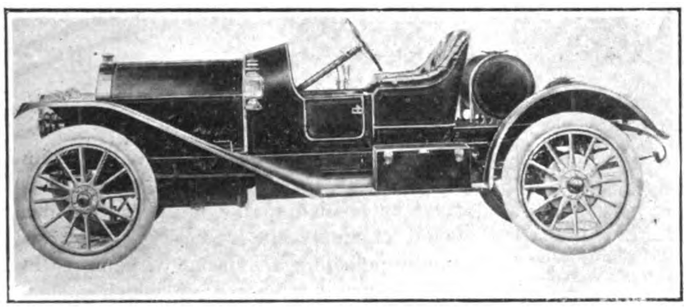

Fig. 10—Showing the National speedway roadster, indicating comfort for the driver and showing large gasoline tank

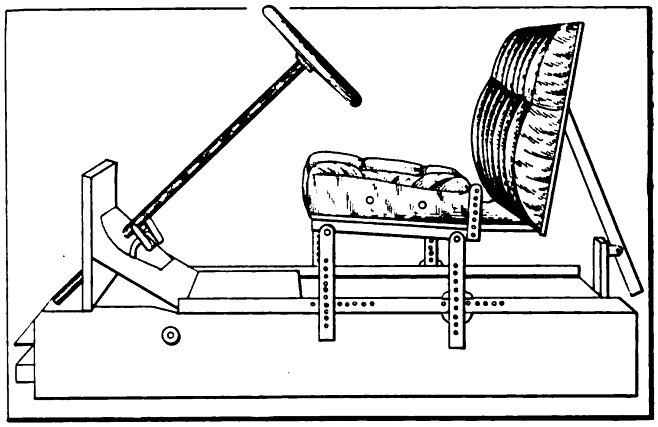
pedals for each make of chassis, but this would not be a big matter.

The space between the seatboards and the footboards was always considered a convenient place to put spares and tools in, but this is gradually disappearing, the total height of the seat being now much lower and the cushions much thicker than they were formerly.

On a long journey when driving a car having a low-confined seat considerable discomfort is sometimes experienced in being forced to keep to one position, and in hot weather the discomfort is accentuated. With the higher seats and more upright steering column formerly used, one could move about a little, and in this way prevent to some extent the fatigue arising from continued driving.

An adjustable driving seat is no novelty on a horsed-carriage, and as it is infinitely more necessary to be able to sit in a suitable position to drive a car, an adjustable driving seat will become popular on some types of automobiles as soon as the public awakes to their advantages.

Where both the brake and change-speed levers, or only the former are outside the front seat panel, the height of the arm rest to driver's seat is important, particularly on some makes of chassis. Even an extra inch will make it extremely uncomfortable to operate the levers which are outside the confines of the car body.



Adjustable seat, with dummy steering wheel and pedals, to enable the builder to fit the car seat to the buyer

Heat Due to Combustion

ACCORDING to accepted authority, the fuel values in British thermal units per pound of the contents of gasoline are as follows:

Carbon burned to carbon monoxide	4,100 B.t.u.
Carbon burned to carbon dioxide	14,500 B.t.u.
Hydrogen burned to water	62,032 B.t.u.
Hydro-carbons burned to carbon dioxide	20,000 B.t.u.

From the above it will be seen that a small proportion of hydrogen in the exhaust products of combustion of a motor represents an enormous weight. It will also be noted that unburned gasoline in the exhaust represents a very considerable waste, and that carbon monoxide, if it exists instead of carbon dioxide, lowers the thermal value of the fuel as used from 14,500 to 4,100 British thermal units.

Correct Tire Pressures

There is great variation in the pressures recommended by the different tire manufacturers. The following is probably a fair average for ordinary loads on the wheels:

Diameter of tire, Inches	Air pressure in tire. Lbs. per sq. in.
2½	45
3	55
3½	65
4	75
4½	85
5	90
5½	95

Lower pressures are used by some, especially for light loads. The pressures run considerably higher in several cases for heavy loads.

Letters Answered and Discussed

Hole in Throttle Valve

EDITOR THE AUTOMOBILE:

[2,842]—Would you please inform me how to fit a set screw or other device on the throttle valve of the motor so that when the throttle is closed as far as it will go the engine will still turn over at slowest speed. The valve is of the butterfly type.

CHAS. SINGER.

New York City.

With a butterfly valve the simplest way of making the adjustment you speak of is to cut a small hole in the valve, as shown in Fig. 1. The hole may be made very small at the start and gradually increased in size until the engine will just carry the car at the lowest possible speed on level ground.

It would be too much of an undertaking to go about fitting a set screw in the case of a valve such as this, and while it would have the advantage of being adjustable at any time this advantage has not enough weight to overbalance the difficulty of making a home-made fitting of this nature.

Engine Loses Power

Editor THE AUTOMOBILE:

[2,843]—Since THE AUTOMOBILE offers to give its opinion to subscribers as to the nature of the trouble and the remedy therefor, when the motor or other working parts of the car are out of order, I am taking the liberty to ask a question.

There are a number of car owners besides myself who are troubled by the fact that the engines will run very well while new, but after they have been run for a short time the advancing of the spark fails to augment the speed of the engine, and the throttle alone is of use. Consequently the engine has not the full power it had at the beginning.

PHILIP NADIG.

Allentown, Pa.

Any motor will run at its best if the spark is advanced as far as possible without the slightest sign of a knock being obtained. If the spark is at this point while running on level ground the greatest effort possible from the engine is being put into driving the car. When ascending a hill, however, the spark will be considerably retarded owing to the slower motion of the motor. The reason that an engine falls off in power after it has been run awhile is that the compression has become leaky owing to piston or valve leaks. The latter are often caused by a particle of carbon which has become lodged beneath the valve. A pitted valve will often be the cause of a considerable loss of power, and the defective member cannot well be remedied by grinding, as the pits will be deeper than it is advisable to grind. In a case of this kind it is best to purchase a new valve at once, or if within the makers' guarantee have them replace it.

Insufficient lubrication is another cause of the loss of power. A new car always requires more lubrication than a car which has been run for a length of time.

Worn gears on the camshaft drive often cause a loss of power owing to the fact that they alter the valve timing.

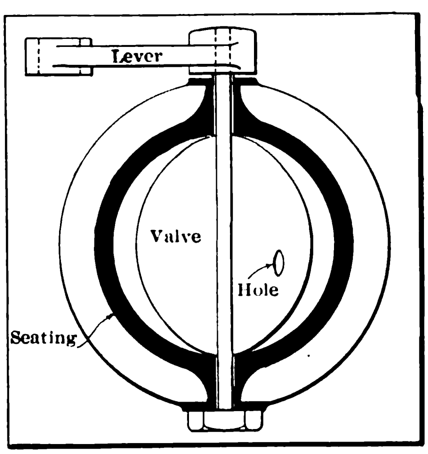

Fig. 1—Butterfly throttle valve with hole cut in valve to permit of slow running

The Editor invites subscribers to communicate their automobile troubles and personal experiences, stating them clearly on one side of the paper. If the nature of the case permits, send a sketch, even if it be rough, in order to assist to a clearer understanding. Each communication will receive attention in the order of its receipt, if the writer's signature and address accompany it as an evidence of good faith. If the writer objects to the publication of his name, he may add a nom de plume.

Loose Bearing Bushing

Editor THE AUTOMOBILE:

[2,844]—The camshaft bearing bushing on my car is loose and shifts its position while the engine is in motion. The trouble is not at all serious, as I am well aware; still I would like to fasten the bushing in position, as I am afraid it will wear considerably if left as it is. I am therefore taking the liberty of asking you the best way to remedy it. Do you think a pin should be driven into the bushing?

L. T. MOOSE.

Canton, Pa.

A pin would not be so advisable as a set screw, which could be fitted in the manner shown in Fig. 2. The screw is so slotted as to be turned by a screw driver, a lock nut is then placed over the screw in order to hold it in place while the engine vibrates. In drilling for the set screw care must be taken that the indentation in the bushing is not made so deep that it penetrates the metal. The correct distance is shown in the illustration.

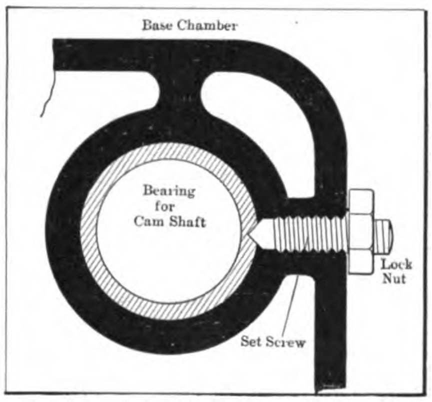

Fig. 2—Manner of fitting set screw to hold camshaft bushing in place

To Darken Brass

Editor THE AUTOMOBILE:

[2,845]—I would like to have you inform me if there is any coating which could be applied to the brass parts which would eliminate the necessity of so frequently polishing it. In one of your recent issues you told of a coating which applied to such parts as could be removed from the machine and heated, but this of course is not applicable to windshields, etc. Any information you care to give me will be appreciated.

F. D. MARTIN.

New York City.

Prepared as here given lacquer will prove efficacious in renovating the bright work, but it is necessary to prepare the surfaces to be lacquered if the results are to be satisfactory. For the surfaces what is needed is a high polish and absolute freedom from grease. The lacquer may be prepared thus: Bleached shellac, 60 grams; Manila copal, freshly powdered, 60 grams; gum mastic, 60 grams; absolute (grain) alcohol, 1 kilogram; coarsely powdered glass, small quantity; allowed to stand for (frequently shaking), 14 days; boracic acid, 1 gram. Filter and use, the best plan being to apply repeated thin coats.

Any desired color may be given to the lacquer by adding aniline dyes. A very little of the dye of the color selected will serve for the purpose. Red and blue will form clear solutions; green must be handled cautiously; it may have to be filtered; yellow is a good dye to handle. In applying lacquers it is desirable to go about it in the same way as shellac is applied—thin coats, deftly applied by means of a suitable brush, with very little rubbing; it will become tacky if it is fussed with very long.

To Open Crankcase Drains

Editor The Automobile:

[2,846]—Kindly tell me of a fitting which could be attached to the drain pipes on the crankcase of my automobile so that they could be opened without getting beneath the car. The way they are fitted at present makes them annoyingly inaccessible, especially if one has a good suit of clothes on at the time.

The drain cocks are fitted to standpipes which rise to the correct splash level, and hence when these drains are opened the excess oil will drain away. Any information you gave me would be greatly appreciated.

Chicago, Ill. Subscriber.

A handy method of opening the drain cocks is to have them arranged so that they are all opened at once. This is done by connecting all the cock handles to a rod and fitting a ring at the end, as in Fig. 3. To this ring a wire is fitted which is run to the front end of the car, terminating just below the radiator. In case it is desired to drain off the surplus oil, the ring on the end of the wire below the radiator is pulled and all the cocks will be opened. The wire is stiff enough so that the cocks can be pushed back to their closed position, which will be determined by means of a stop. If it is desired a spring may be fitted which will hold the rod in a closed position unless there is a pull on the wire.

Raises Magneto Question

Editor The Automobile:

[2,847]—What advantage has a high-tension magneto over the low? As I understand it, an engine will run just as well with a low-tension magneto as with a high, and at the same time one can crank on a low and not on a high. If the low is just as good, why the greater cost of the high?

Bango, Texas. J. K. Stone.

The high-tension magneto is practically nothing more than a low-tension magneto with a coil in the same casing. Hence the high-tension will cost more than the low since it is more complicated. Low-tension ignition, such as is used with the make-and-break system, is not as simple as the spark plug used with the high-tension system. In order to use a plug with a low-tension magneto a coil is necessary to produce a high-tension current.

The engine can be cranked when fitted with a high-tension magneto.

Air Cock on Intake

Editor The Automobile:

[2,848]—Several automobile drivers of my acquaintance have fitted a small pet-cock in the intake pipe, about 4 inches above the carbureter. After starting the engine with this pet-cock closed, and then opening it to obtain more air, a very noticeable increase in the speed of the engine will result. Again when a car is running at a speed of 20 miles per hour on the road, when this pet-cock is opened, the speed will increase from five to seven miles per hour.

The device has been tried on a variety of cars and in all cases the results have been practically the same—a greatly increased mileage per gallon of gasoline.

Kindly advise what you think of the idea and whether any bad effects will arise from its use.

Fred A. Moore.

Croswell, Mich.

That the device works well after having

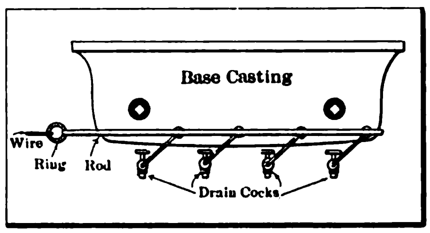

Fig. 3—How cocks may be connected so that they can all be opened at one time

been tried on several cars seems to indicate that it is of some merit, and it is natural when the reasons for it are examined. The modern carbureter, although a marvel of automatic flexibility, has to be adjusted so that all speeds will be equally well taken care of. If the carbureter were set so that the highest possible efficiency were obtained at high speeds it would probably be impossible to start the engine.

The auxiliary air valve was invented for the purpose of supplying more air to the mixture after the engine gathered speed, but even with this valve the maximum efficiency cannot be obtained at every speed.

One objection to the cock fitted as you suggest is that the dust in the air will be drawn into the cylinder and will do some harm after awhile. If gauze were fitted to the cock and a handy means of varying the opening were placed on the dash so that it could be operated by the driver, it would be a useful adjunct in the hands of an able operator who desired to get all the good possible out of the car.

Gets Too Much Oil

Editor The Automobile:

[2,849]—I would be greatly obliged if you would tell me how to lessen the supply of oil given by the plunger pump in the oiling system of my new car. The supply is just enough greater than what is necessary, to make the motor smoke very unpleasantly. If you could help me out of the difficulty by publishing a solution of the problem in an early issue of your valued paper it would be appreciated.

Tuckahoe, N. Y. H. W.

Remembering the fact that it does not harm a new car to receive a little excess of oil, the adjustment may be made on the pump itself by regulating the length of the stroke. On nearly all plunger pumps there is a nut which may be turned down, thereby shortening the stroke. Since the amount of oil delivered by the pump is exactly proportional to the length of the stroke of the pump, this regulation will correct the fault.

Clutch Is Fierce

Editor The Automobile:

[2,850]—Would you kindly tell me how to remedy a clutch which picks up very suddenly? The clutch is of the leather-faced cone type and instead of picking up easily, as a clutch should do, it will grip with a very jerky pull as soon as it is engaged. If there is anything I can do to make the clutch less fierce I would appreciate it if you would direct me.

Tottenville, N. Y. L. K. H.

The repair can be very readily made at home if the garage is equipped with the average amount of tools, or if they can be borrowed or bought in the neighborhood. Referring to Fig. 4, a drilled piece P_1 is bolted to the male member of the clutch in such a way that P_1 is parellel to M. A tube P is placed about the bolt which passes through P_1 and a spring is inserted, so that the leather L is held against the flange B of the flywheel F. The bolts B_1 and B_2 are fastened tightly in order to prevent any working loose, while the bolt which passes through P_1 is held in position by a lock nut L_1 by means of which any adjustments may be made permanent. There should be at least four of these inserts placed upon the clutch in order to secure a uniform effect.

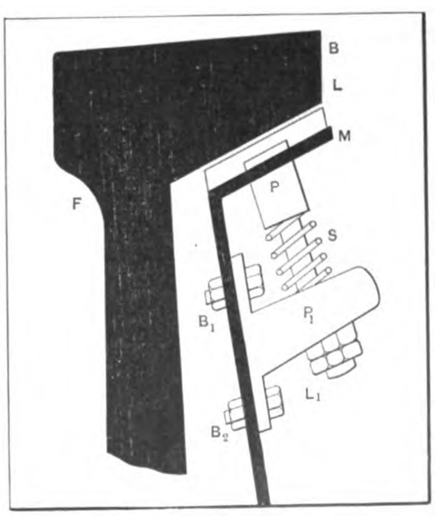

Fig. 4—Showing method of inserting springs in clutch to give easy engagement

Little Bits of Motor Wisdom

Pertinent Pointers for Repairman and Driver

Use of Feather or Key—Where one shaft is forced to slide upon another and it is not desired to go to the expense of squaring the shaft for the length that the slide is required, a key or feather of the type illustrated in Fig. 1 is fitted. With a fitting of this nature the outer or sliding piece may work in either direction with very little resistance to its motion if the slide be well lubricated. This piece of mechanism is used to a large

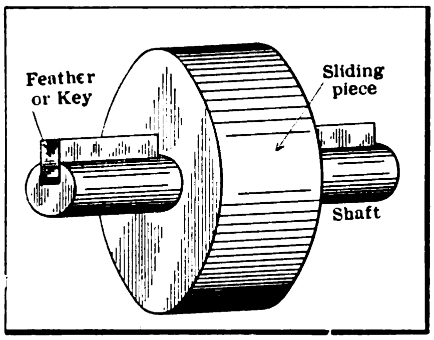

Fig. 1—Showing method of arranging feather or key as a guide for sliding piece

extent in change gear devices, the loose collar slipping along the shaft in either direction according to the motions of a hand lever which is fitted in such a manner that the operation of moving the different gears in mesh is in accordance with the conditions under which the automobile is traveling.

In operating the sliding sleeve by means of a lever, the usual method is to have a forked arm which touches a collar so that the sleeve may be moved in any direction. At the same time the fork is free to have the sliding component which will naturally be a part of the motion where the arm turns about a pivot and, at the same time, imparts a straight-line motion to another shaft.

The Gear Pump—In place of the plunger pump with its ball check valves, the gear pump is finding favor with many manufacturers. It is very simple to arrange a satisfactory drive for the gear pump, since it is driven with a rotary instead of a reciprocating action. Instead of the necessity of an eccentric arrangement to produce the straight line or reciprocating motion necessary in a plunger pump, the gear pump can be driven directly from the camshaft or other rotating part by means of simple gearing.

The pump is shown in Figs. 3 and 4, which illustrate the exterior and a section through the dotted line shown on this cut. The oil enters through the port marked "suction" in the sectional view, and is taken around by the wheels to the delivery side; the oil cannot pass between the teeth in the quantity that it is drawn in by the suction, so it is squeezed out through the delivery port.

With the method of delivery employed in this type of pump it is evident that a large head could not be overcome, as would be the case if the oil were to be lifted to any great height. For the requirements of an oil pump, however, the method is very satisfactory for all cases, as the pressure required does not as a rule amount to more than three or four pounds where the force-feed system is used.

If the rotary gear pump is driven off the camshaft by means of a gear and straight shaft, it is a very desirable feature to insert a spring connection in the shaft so that, should the pump jam, the spring release will work and allow the pump to remain at rest without any of the parts having been broken. This is effected by putting in a spring which will be strong enough to hold the shaft while turning, but which will, in case the pump should jam, break or in some cases slip, so that it is no longer a means of rigid connection, but allows the upper part of the shaft to turn freely.

Where the gear pump is used it is very customary to fit a by-pass as a means of regulating the quantity of oil delivered to the various bearings. The by-pass is so constructed that by turning a lever a greater or less amount of oil may be allowed to pass through it; but when all the oil that can possibly be directed through the by-pass is allowed to flow through this outlet, there will still be a sufficient quantity passing through the oil leads to lubricate the bearings at slow speed. This is done as a matter of precaution so that all the oil will never be accidentally shut off from the engine while the latter is running.

The pressure on the gauge, where such is fitted, in conjunction with this type of pump should be allowed to register a little more with a new car than with one which has been run long enough for the bearings to have worn themselves to a good running fit. The pressure required in city driving will be about a pound less than for the country, as an average. Very often the overflow from the bearings lubricated by the force-feed system forms the basis of an auxiliary splash system.

Trembler Points Out of Line—It will sometimes happen that the contact points on the magneto timer are not properly in line, and unequal wear will result which will greatly hinder the delicacy of adjustment which is such a necessary feature in this part of the coil. In the accompanying illustration, Fig. 2, C is the primary core, T the trembler, P and P_1 the contact points, N and N_1 the lock nuts and S the set or adjusting screw. The trembler is held at the post H. In a case of this nature a small piece of metal should be brazed on the trembler and then filed square so that when vibrating there will be equal wear on all parts of both contact points.

The adjustments on the set screw S should be made so that when the circuit is closed a continuous droning hum will be given forth by the vibrator. A rattling sound is an indication that the vibrator is working too slowly against the spring. If the latter is the case the tension on the spring should be relaxed by loosening the adjusting screw. When the proper adjustment is made as regards the contact points and the spring tension the lock nuts are tightened into position so as to secure a

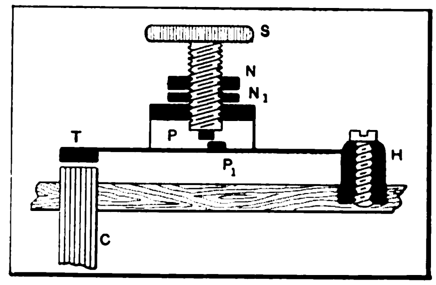

Fig. 2—Illustrating a case where the trembler contact points were out of line

permanent adjustment. The lock nuts are very necessary here, as the continual vibration would soon loosen the set screw if there were no method of securing it in place.

Short Circuits—A spark, in leaping the gap between the two sparking points of the spark plug, overcomes a large resistance even if the operation takes place in the open air; but when the air is charged with hydrocarbonic gas this resistance is increased. A slightly compressed charge of gasoline and air may be fired by a spark which would be too weak to fire a charge which has been compressed to the 70 pounds per square inch pressure which is the general rule in automobile engine practice. It is therefore evident that the resistance is higher in the compression space of the motor than it is in the open air, so that an apparently good spark may not be a spark at all after it is enclosed within the cylinder. This loss of the spark when acting through the compressed medium is due to a short circuit which is caused by the fact that the current, seeking the path of least resistance, finds a way of passing into the ground without crossing the spark gap. The insulation might not leak at all under atmospheric conditions, but just below the pressure at which the spark crosses the gap the current finds a spot in the insulation which offers less resistance than that encountered at the sparking points.

If this leak takes place in the coil it will generally be beyond the scope of the amateur to make his own repairs. A new coil will have to be bought if the damage has gone far, as the internal spark will burn out the surrounding insulation in a very short time. If the leak is at the spark plug, as is very often the case, owing to a cracked porcelain or defective mica insulation, a new plug will quickly eradicate the difficulty. Defective insulation is apt to cause a short circuit at any place along the line. This is especially the case in high-tension wiring, which should be carefully watched, as a little dampness or chafing against moving parts of the motor may be responsible for the damage.

A fault which occurs with dry batteries at times, if they are not carefully packed, is that they are likely to rub together owing to the vibration of the car and thus wear the cardboard boxes which hold them and

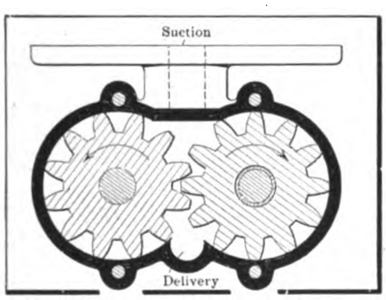

Fig. 3—Section through gear pump at dotted line shown in exterior view

allow the zincs to come in contact with each other. This, of course, does not happen very often, as the batteries as a rule are held in a tight box, which does not permit any chafing action to take place between them.

Keep Breather Pipes Clear—As the piston descends, the air beneath it is compressed and hence offers a resistance to the motion of the engine. In order to reduce this resistance breather pipes are fitted on the motor to allow of a free passage of the air in either direction. The air will flow in and out of the crankcase according as it is sucked in by the ascending piston or blown out by the descending. When the breather pipes become choked, resistance is offered to the free passage of the air and hence work will have to be done by the motor in overcoming this resistance. This work is a direct loss since it is put into something which is not necessary and is no factor in driving the car.

The breather pipes are generally fitted with a strainer to keep dirt from entering the crankcase. Very often the strainers fulfill the double duty of keeping the crankcase clean and straining the oil which is put into the crankcase, as the oil is often supplied by this means where the splash system is used. A periodic cleaning of this part would add to the efficiency of the engine.

Firing at Correct Time—Next to having the cylinders all firing at the same relative piston position, the greatest item of importance in the motor is to have the charges ignited at the proper time, or when the piston is at the point most suitable for developing the greatest power.

The ideal position for the maximum explosive effect would be at top dead center: but since the internal combustion engine revolves so rapidly, this is a condition which can never obtain even in the best designed engines. When the gas is first ignited, it rapidly expands owing to the heat of its own combustion. The flame is taken up by the surrounding particles of gas and is passed through the whole charge. This takes place very rapidly, but not rapidly enough to obtain the expansion at constant volume which would be the ideal state of affairs. Besides the lag in the explosion there is an appreciable lag in the passage of the electric current through the secondary winding, and therefore when the engine is traveling at high piston speeds the spark lever will have to be advanced a certain amount on the quadrant to allow for this lag. The sooner the charge is ignited, the sooner the maximum pressure will be developed in relation to the stroke and hence the greater the power that will be produced by the motor.

The condition of the mixture and the intensity of the spark are very large factors in determining the proper and most effective firing point. In driving the car the proper position of the spark lever will vary with the conditions under which the car is working, and it is largely a matter of experience on the part of the driver to have the spark in the proper position to obtain all the power of which the motor is capable. As a general rule the greatest power is obtained with the greatest spark advance possible, without having the slightest sign of a knock. In special cases, as in hill climbing or in starting the motor, where the engine turns over very slowly, the spark is retarded, as a back-fire in either of these cases would have bad results. In cranking the machine if the spark has not been sufficiently retarded a serious accident may occur that would result in a broken or severely strained arm. Cases have been known where death was caused by this same occurrence. In the case of a hill, if the charge should be ignited too soon the power would be expended on the piston at the wrong time and hence would be apt to stop the engine.

When firing too late the exhaust pressure is far above what it should be; and since the temperature of the gases depends directly on the pressure, they are also far too hot. This heats the cooling water of the engine to such an extent that it frequently boils, escaping in the form of steam from the radiator cap and other points where such leakage is possible. Besides the overheating there is a loss of power in running the engine with the spark too late, as the high terminal pressure re-

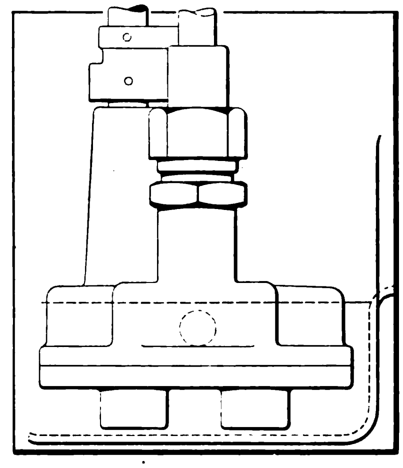

Fig. 4—Exterior of gear pump often used in connection with force-feed oiling

duces the mean effective pressure and hence the horsepower produced by the motor.

Worn and Loose Gears—Where gears have been allowed to wear it is very often the case that they are not in the same relative position with each other that they were when the parts were first assembled. An instance of this kind may be taken in the case of a camshaft whose driving pinions have become so badly worn that in revolving the camshaft lags far behind the position taken when the machine was new. The same may be said of a gear which is loose or a cam which has worked loose and hence is in a different relative position from that formerly occupied.

Where the gears have worn to any extent the action, instead of being smooth and unbroken, may proceed in a series of jerks. This will result in a rattling noise which will readily make itself heard above the sounds given forth by a smooth-running car. The timing of the operation which depends upon such worn or loose parts is very sure to be incorrect. In the case of a camshaft the opening and closing would both be late.

My 1912 Automobile

Some Conceptions of What the Ideal Car Should Be

Illustrates His Ideal

EDITOR THE AUTOMOBILE:

The "1912" automobile should be about 40-50 horsepower, having an en bloc T-head motor with a 4 1-2-inch bore and 6-inch stroke. All valves should be enclosed with dust-proof covers. Magneto, oil pump and water pump should be mounted on a cross shaft at the front. The fan should be bevel gear driven, thus doing away with all possible belt troubles. Ignition should be by means of high-tension magneto and storage battery. Lubrication should be of splash type with an oil pump to raise the oil to the top of the crankcase. An ample sized float-feed carbureter with an air and gas adjustment on dash would be required.

The clutch should be of the contracting band type, thus doing away with thrust against motor and other bearings, and permitting of easy adjustment. The gearset should be of the type where gears are always in mesh, thus doing away with possibility of stripping gears and permitting of a comparatively noiseless shift of gears. The transmission shafts should be mounted on roller bearings, and case to be cast with arms to bolt to rear arms of motor, thus making a unit power plant. Drive should be by shaft with two universal joints.

The wheelbase should be about 120 inches, allowing ample leg room and giving easy riding effect. The springs should be semi-elliptic front 42 x 2 1-2 inches and three-quarter elliptic rear 44 x 2 1-2 inches. The tires should be 36 x 4 inches front and rear, Q. D., on demountable rims.

The front axle should be of drop-forged I-beam type with roller bearings in the wheels, and steering connections above and behind the front axle. The rear axle should be full floating with all roller bearings, and be of a single piece of pressed steel with removable cap to permit of easy access to the differential and bearings.

The control should be by means of an 18-inch steering wheel and adjustable worm and sector. The gear shift to be operated by a lever at right side in H quadrant. The pedal arrangement is standard. Spark and gas operated on top of wheel and foot accelerator. The emergency brake to be worked by side hand lever which releases the clutch when applied, thus lessening wear on transmission shafts.

The body should be fitted with seats having high backs and low bottoms and long leg room provided for, thus making touring more comfortable. (Other details can best be seen from the accompanying drawings.)

The car should be equipped with full set of electric lamps and lighting system, electric signal, top, windshield, shock absorbers, spare rim, tools and other minor conveniences.

This car, weighing probably not more than 2,500 pounds, and with first-class materials used throughout, should cost about $2,500 f.o.b. the factory.

Passaic, N. J. JOSEPH A. LANGE.

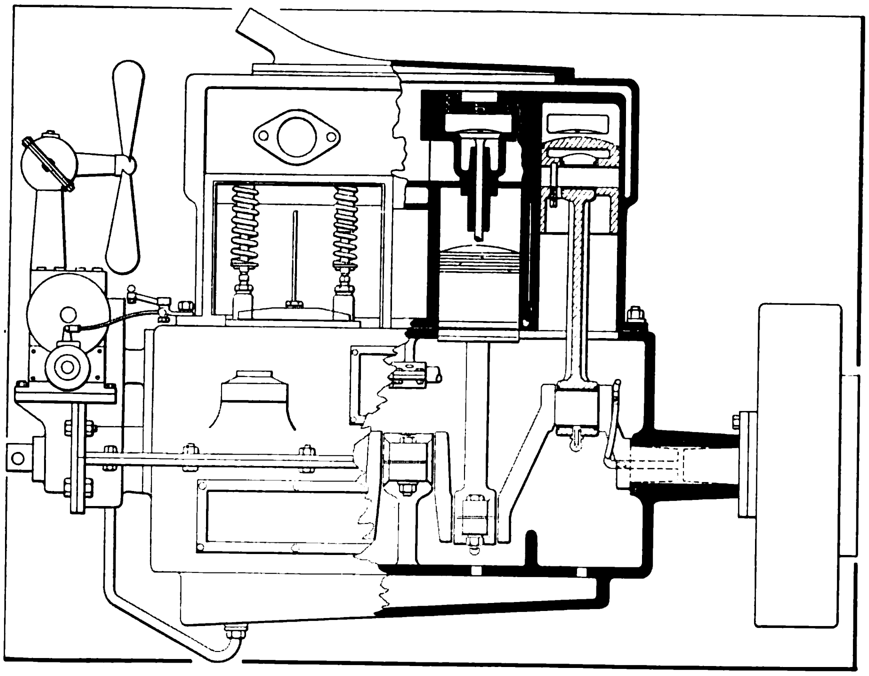

Fig. 1—View of motor as drawn by an "Automobile" reader in illustrating his ideal car

Working Parts Enclosed

Editor THE AUTOMOBILE:

The following is my ideal for a 1912 machine:

The motor should have four cylinders with 4 1-2-inch bore by 5 1-4-inch stroke giving a conservative rating of 32 horsepower. The cylinders should be cast en bloc with valves in the head operated by a single overhead camshaft driven by means of a silent chain from the crankshaft. The ignition should consist of high-tension magneto and storage battery, each system being entirely separate. The lubrication should be of the force feed type through hollow crankshaft. The crankshaft could be carried on two large ball bearings.

All working parts of the motor should be enclosed and protected from dirt. A large cap could fit over the valve mechanism and protect it from grit.

The clutch should be of the multiple-disc type and should run in oil. The clutch should be in the same housing as the transmission and should be located amidships.

The transmission should be four-speed selective type, with direct on third, and should be fitted with ball bearings.

The drive should be by shaft, with two universal joints to a full floating rear axle with nickel steel driving shafts. The front axle should be of I-beam section and should have generous steering knuckles. In fact, all the steering parts should be made strong and easily adjustable for wear.

The wheels and differential should run on large ball bearings.

The frame should be underslung and inswept in front. It should be supported by long, flat, semi-elliptical springs both front and rear and the springs should be fitted with shock absorbers.

The tires should be 36 x 4 front and 36 x 4 1-2 rear and mounted on demountable rims. The wheelbase should be 115 inches.

Control should be within easy reach and should be on the right-hand side.

The body should be of the two-passenger torpedo type with gasoline tanks and room for tires on rear deck.

The equipment should consist of top,

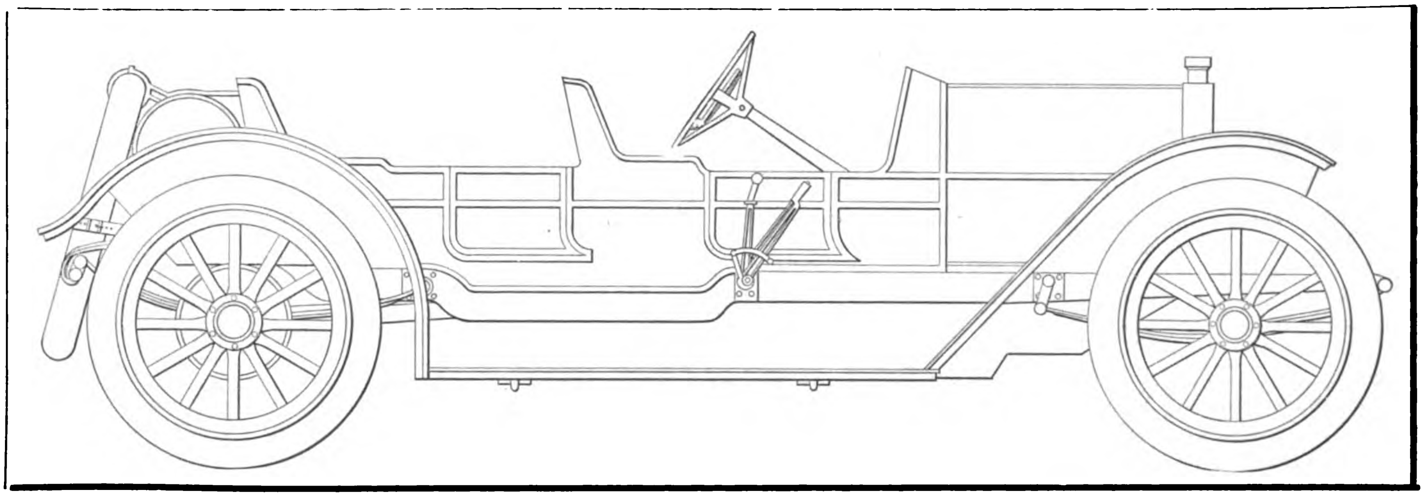

Fig. 2—Type of body suggested by a reader of "The Automobile" in describing his ideal 1912 car

windshield, speedometer, clock, five electric lamps, electric horn, generator and battery for horn and lamps, shock absorbers, and demountable rims with two extra rims.

As this car should be of the very highest grade its price could scarcely be below $3,750.

MARTIN BURKELMAN.

New York City.

Want Five Speeds

Editor THE AUTOMOBILE:

This is, in brief, my conception of the 1912 model car. The motor should have four cylinders cast in pairs with a bore of 90 mm. and a stroke of 180 mm (3 1-2 x 7 1-2 inches) and a nominal horsepower of 20.

The ignition should be by means of high-tension dual magneto system and the lubrication of the force-feed type, the pump being integral with the motor and with no connecting splash. Each part should be oiled separately. The motor should be equipped with either a Zenith or Claudel carbureter and should deliver its power through a leather-faced cone clutch.

The body should be supported upon semi-elliptic springs and I-beam frame members, the rear axle being of the semi-floating type. The wheelbase would be specified as 137 inches. Transmission should give five forward speeds and a reverse.

The motor should be equipped with a self-starter and motor-driven tire pump, while the steering wheel should be fitted with a locking device. A speedometer should also be carried and the brakes controlled by pedal and hand lever.

The body should be a four-passenger type fitted with an external exhaust pipe (without muffler) running along the footboard. Right-hand drive should be fitted, with the levers outside the torpedo body. The hood and body should be in exact alignment, and the door should have the fastening locks inside. The gasoline tank should be located partly under the front seat and partly in the tonneau, furnishing a foot rest for the passengers in the rear compartment. The rear seat foundation should be located directly on the chassis, with tool boxes under the floor of the rear platform of the car, one on each side of the drive shaft. A double extension hood should be fitted with two headlights, two sidelights and a rear lamp—all of the electric type. The glass front should be in two pieces, coming over the steering wheel. Price $2,000.

Here are some reasons for my choice: Long-stroke motors (to my mind it ought to be 1 to 2), are nervous motors; they pick up speed much quicker than the short-stroke type. I own a motor with an 80-millimeter bore and 160-millimeter stroke and it performs extremely well. I consider detachable wire wheels a luxury and believe their worth has been frequently demonstrated. Leather cone clutches are the smoothest for starting in city traffic. The five-speed transmission is a 1911 innovation which has made good in the Boulogne light car races, especially for long-stroke motors. External exhaust pipe (which can be made so as to avoid all noise) would prevent heat invading front of torpedo. R. DE BEAUDIGUES.

Natoye, Belgium.

THE AVERAGE CAR

The invitation to our subscribers to describe their ideal 1912 car has struck a popular chord. The responses show a wide appreciation of the salient points of car design and a knowledge of the points which tend to reliability and comfort. THE AUTOMOBILE *hereby continues the invitation to its readers to mail in their conception of the features which should be embodied in next year's car. The information given should include such points as:*

Horsepower	*Stroke*	*Drive*	*Front axle*
Cylinder type	*Ignition*	*Springs*	*Control parts*
No. of cylinders	*Lubrication*	*Wheelbase*	*Body features*
Cylinders, how cast	*Clutch*	*Tire sizes*	*Equipment*
Bore	*Gearset*	*Rear Axle*	*Price*

In addition to giving these details the reasons for your points of selection should be stated concisely and clearly.

As a benefit in the matter of comparison some details of the average cars for 1911 are given below.

Each communication must be legibly written on one side of the paper only; it must be properly signed with the writer's full name and address, and if the writer does not wish his own name to appear in print he may request the use of any nom de plume.

Any reader desiring to make line drawings, showing details of his ideas of his car or some of its parts, is requested to do so.

Editor THE AUTOMOBILE.

Digest of the Leading Foreign Papers

MOTOR CULTIVATORS, HARROWS AND HOES must pay for themselves during the short season when there is need for their services, but in a large country with a single language the season may be considerable lengthened if the owners of such agricultural machines travel with them from South to North, as is now done with threshing machines in the United States. Under different circumstances it is highly desirable from an economical viewpoint that the motor element in the machines be detachable and applicable to other purposes. Their utility generally depends mostly upon the possibility of performing a great deal of work with them while the weather is favorable and with a minimum of human labor. In the case of beet culture and for other crops where each plant should preferably be isolated, the machines can never do as thorough work in weeding and hoeing as may be done by human hands, as they cannot work so near to the plants, but, as compared with machines drawn by animals, they destroy a great deal less of the desirable growth in passing through a field, and the scarcity of human labor in the country, the world over, has made the mechanical problems involved in the application of the motor principle to this class of work as important as any which are encountered in the automobile industry. Taking this view, a number of local automobile clubs in France in conjunction with several agricultural societies arranged for a competition of motor hoeing machines in the foresummer of 1911 with the co-operation of the syndicate of French sugar manufacturers. The trial took place in a beet field of 11 hectares adjacent to a highway lined with trees, and a heavy rain on the preceding evening had left the soil very wet and slippery, especially under the trees. Nevertheless, the three machines which were entered for the competition performed the work expected of them so nearly satisfactorily that a few changes in their construction should suffice for introducing them broadly in agricultural work. The largest machine in the trial was one made by the Bajac Machine Company, of St. Quentin. It works six rows with a two-cylinder motor of 8 horsepower, weighs 1,400 kilograms and requires two attendants, one who steers the machine from a seat and another who operates the right-angled hoeing irons according to the requirements in the field. For the turns, where every other machine in this class is difficult to manage so that the rows of plants are not injured or the soil upheaved, this machine has a special arrangement whereby the inner wheels turn on metal sheaves which after the turn are again raised and secured to the frame. The field in this case had been prepared with a four-row drilling machine and planter, and the six-row hoeing machine did not fit into this work, but apart from this trouble, which calls attention to the need of standardization in construction, the machine demonstrated its practicability and showed that even the isolating of the plants could be conveniently taken care of.

The second machine was one designed and built by Mrs. de Mesmay, of St. Quentin. It is driven from a single-cylinder motor of 5 to 6 horsepower located above the rear wheels. The front wheels are close together, separated by only a single row of plants. The weight is 900 kilograms and the machine is conducted by one man. The trial showed that the rear wheels of this machine were too narrow, cutting into the soft soil and giving insufficient adhesion where the soil was wet, and, while the operation by one man was considered an important advantage economically, it was observed that the driver could not conveniently regulate the depth at which the hoe blades should work, especially where the surface was uneven. The motor in this machine is, on the other hand, so located that it can be used for all sorts of stationary work on the farm without being dismounted. The third machine was one made by Pruvost-Gandas, of Airennes. It works four rows, weighs 800 kilograms and is equipped with a single-cylinder motor of 5 horsepower. As in the Mesmay machine, one man does all the work but is compelled to turn around in his seat to watch the hoe blades, and this may interfere either with the steering of the machine or with the quality of the weeding. It was the opinion of the judges that the construction of the one-man machines might be modified without great mechanical difficulties so as to enable the conductor to watch the penetration of the hoe blades at the same time as the direction of the front wheels.—From the weekly circular of the Syndicate of French Sugar Manufacturers, as republished in *Allgemeine Automobil Zeitung*, No. 34.

CONTRACTIONS AND EXPANSIONS TAKE PLACE IN ARTICLES MADE OF HARDENED STEEL for several years after the articles have been produced and fitted and independently of the changes due to temperature. In measuring instruments and close-fitting parts the changes are sufficient to cause inaccuracies and troubles, and they point to internal tensions whose relief, when it is brought about through the mere lapse of time, may mean a reduction of strength as well. With regard to measuring instruments two methods have been employed for avoiding inaccuracies due to this cause. One consists in hardening only the ends or exposed parts of the instruments, but opinions have been sharply divided on the efficacy of this method. The other, which is of broader application, consists in keeping the hardened article under a heat of 150 to 200 degrees centrigrade for some length of time, thereby relieving the internal tension, though with a slight sacrifice of hardness. But no rules for such low-heat annealing have ben developed and tested. It was not definitely known if one process of reheating continued for ten hours, for example, was equal to several reheatings of shorter duration but extending over a longer period. A series of experiments were not undertaken at the German government station for the testing of materials. Samples of articles, 10, 25, 50 and 100 millimeters long, were obtained from four different manufacturers (this number responding out of thirty-five firms whose co-operation was solicited) and these were measured at five different times during the period from November, 1906, to December, 1910. The deviations from the normal lengths of the pieces were recorded and tabulated with the use of the Reisenecker measuring machine which allows an expansion of 0.011 millimeter per meter length for each degree centigrade above normal temperature, while the tolerance relating to the accuracy of the measuring operation lies between 0.0002 and 0.003 millimeter. The samples showed remarkable difference. The samples of one firm kept on contracting from time to time, those of another showed mostly expansions; those of a third firm both contractions and expansions. In one case none of the samples gave variations exceeding one-thousandth of a millimeter; in another case the variations ran to five one-thousandths and above. The expansions and contractions were nowise proportionate to the lengths but were reduced where only the ends or exposed parts had been hardened. Many other experiments were conducted with articles made from steels of different composition or which had been subjected to different heat treatment. The upshot of all the experiments, as detailed by the authors, was, however, that in all cases changes in dimensions and shapes could be obviated practically by one reheating at 150 degrees centigrade continued for ten hours. The practice of immersing hardened steel parts in boiling oil for a considerable length of time before regrinding to exact dimensions was thus practically sustained.—A. Leman and A. Werner in *Werkstattstechnik*, August.

ON THE ORGANIZATION OF A CASEHARDENING DEPARTMENT Léon Guillet, the well-known authority, offers the following advice based on his practical experience: The department should be physically divided in two sections, each with its separate personnel, both under one superintendent. The cementation process requires much less precision and ability than the subsequent hardening and, besides, in any factory there are other pieces to be hardened than those which have been cemented. The superintendent should have near him the receiving booth through which all pieces should pass for checking and inspection before treatment. The system of control at this booth forms a separate subject. The cementation department proper should comprise (1) a room for boxing the work, with the necessary tools; (2) adjacent compartments for the manufacture of cementation material, with pestle crusher and reserve stock; for storage of boxes and filler earth; for a little shop to take care of the preparation of sheet metal parts used in the reserve work (copper plating or other means for excluding certain portions of the work from the cementation process) and, in large establishments, for the manufacture of boxes; (3) the furnace room, spacious and ventilated, and (4) a cooling area, which may be a shed, in which the boxes are placed on rails to avoid contact with the ground and moisture. In front of the superintendent's desk, to be consulted by him and by the workman who attends the furnaces, a registering galvanometer should be placed, connected by fixed wires with the pyrometric couple-rod, and, as the latter may be placed in one or the other among the furnaces, there is need of a certain number of wiring posts before the furnaces and before the galvanometer. The latter is also connected with the sight glass which must be movable before the furnace. The wires which connect it with the galvanometer are simply passed along on a cable strung before the battery of furnaces and are not cumbersome in the shop. Datum posts in the ground admit of moving the sight rapidly from one furnace to another. It is well to measure the temperatures every fifteen minutes, and with a battery of six furnaces this operation does not occupy more than five minutes in all, so that the same man can read the temperatures and regulate the furnaces, as is preferable.

In the hardening section the pieces which require no cementation are received direct from the receiving booth at the entrance to the department, but the hardening section should have a separate booth where the foreman of the hardening room under his own responsibility receives the cemented pieces which he is to harden. At this booth there should be found all the calipers and other tools necessary for verifying the pieces which are delivered to him and seeing whether the cementation alone has not caused some defect, especially if the pieces are not scaly or oxidized. Outside of this receiving booth of its own, the hardening section comprises the battery of furnaces which usually will be of different types; a muffle furnace, salt bath furnaces and even furnaces of different dimensions for large, medium and small pieces. As most cemented pieces must be hardened at 1,000 degrees or at 750 degrees, it is useful to have furnaces of these two temperatures to avoid loss of time.

In front of the furnaces there should be found the battery of baths. There can be a series of movable troughs and of fixed basins. The movable ones are intended for small work and for baths which need not be very cold. They should roll on rails. The fixed basins are best sunk into the ground so that their rims are just flush with it and are intended for large pieces and for cooling by forced circulation of water. A hardening shop should have a large water bath, a smaller water bath, an oil bath (the preferred composition of the oil is, two parts of rapeseed oil, two parts of nut oil and one part of olive oil) and one bath more active than oil and less active than water, such as lime water.

To measure temperatures in the baths, thermo-electric couples with indicating or recording galvanometer are preferred. If one wants greater precision, an electric-resistance apparatus may be used, but the recording instrument based on this principle is very delicate and should not be considered an industrial tool.

The hardened pieces should be checked off and returned to a checking bureau situated near the superintendent, where they are recognized as good or bad. In the first case they are passed to the mechanical shops; in the second they are returned to the hardening room, and if suitable treatment continues to give a poor showing at the checking roof, the quality of the original material should be again verified.

With this equipment the cost of work should not be excessive. Night work, however, always gives poor results unless there is a complete double shift of workmen, including two superintendents.—*Le Génie Civil,* July 29.

Calendar of Coming Events

Shows, Meetings, Etc.

Sept. 25-30........Atlantic City, N. J., Convention and Exhibition of the Carriage Builders' National Association.
Oct. 7-14..........Chicago, Ill., Show of Chicago Automobile Trade Association.
Jan. 1-5, 1912......New York City, Grand Central Palace, Annual Show, Automobile Manufacturers' Association of America.
Jan. 6-13..........New York City, Madison Square Garden, Twelfth Annual Show, Pleasure Car Division, Automobile Board of Trade.
Jan. 6-20..........New York City, Madison Square Garden, Annual Show, Motor and Accessory Manufacturers.
Jan. 10-17........New York City, Grand Central Palace, Twelfth Annual Show, National Association of Automobile Manufacturers; also Motor and Accessory Manufacturers.
Jan. 15-20.........New York City, Madison Square Garden, Twelfth Annual Show, Commercial Division, Automobile Board of Trade.
Jan. 18-20.........New York City, Annual Meeting of the Society of Automobile Engineers.
Jan. 27-Feb. 10....Chicago Coliseum, Eleventh Annual Automobile Show under the auspices of the National Association of Automobile Manufacturers. Pleasure cars, first week. Commercial vehicles, second week. Accessories, both weeks.
March 2-9.........Boston, Mass., Tenth Annual Show, Boston Automobile Dealers' Association, Inc.

Race Meets, Runs, Hill-Climbs, Etc.

Sept. 30..........Guttenberg, N. J., Track Races.
Sept. 30..........Bridgeton, N. J., Track Races, South Jersey Motor Club.
Sept. 30..........Flint, Mich., Track Races.

The Will and the Way

TWO years ago one maker refused to build fore-door bodies because he did not know how to ventilate them. He said they could not be satisfactorily ventilated and that consequently they would never come into favor. After he saw the error of his ways and realized that he would become a back number if he did not discard some of his old bodies and build fore-door types, he tried to start a criticism against those who advocated the fore-door body on the ground that they were injuring the industry by compelling many makers to build over bodies that were antiquated. This is a deplorable case of being behind the times. When a maker is so slow that he is caught with a line of old-fashioned goods on his hands he should have enough pride to suffer his loss and use every effort to get into the van. A maker who is so busy that he cannot follow the trend of public demand closer than this should take a holiday every week and get out among the public, keep his ears and eyes wide open and find out what is doing. It is just as important to know the public pulse as it is to have a good designer.

But makers of automobiles must get out into the buying world for other reasons than studying the body requirements. They can find out very well just where their cars are weak and what the public thinks of them. In the early days many makers personally went on the long reliability runs, attended the hill-climbs and visited the races with the sole object of studying the performances of their own cars as well as those of other cars. Of late there has been a falling off in this respect. Many makers who have built up reputations on their achievements in contests are now more or less content to rest on their laurels. While they have been resting the young bloods of the industry have been toiling upward in the night. The younger element has adopted the latest designs, and now the older heads are compelled to fall in line. The automobile maker who imagines that his car is perfected, that it will sell in its present form for two, three or perhaps four seasons yet to come, is making an error. He will be rudely wakened some day with a lot of unsold cars on his hands. That maker does not exist to-day who can safely sit down and say, "Our car is perfected; we have nothing to do but manufacture and fill orders." The public is getting wiser every day in the matter of automobiles; and reputation, while it will dispose of the factory output for a season or so, is not enough to bank upon for the future. As one season succeeds another, fresh examples are given of old houses losing their hold. The only rule is to keep everlastingly at it. Keeping to the front to-day demands unity in every department; it demands keeping in touch with the latest constructions in every respect, and it demands following the public sentiment.

* * *

Studying Salesmanship

THESE are the real testing days. A year or so ago the salesman was more or less of an order clerk. He used to busy himself writing out orders. The sales manager was a distribution chief. His big job was to satisfy dealers everywhere that they were getting their correct allotments of cars at the specified times, and that one was not being given an undue lot of automobiles at the expense of some other one. Those days are over. To-day the salesman has to sell cars. Many of the old salesroom decorations are missing. They made good when people bought cars, but could not stand the pace when the rule became one of the salesman selling machines.

But the salesman is not the only selling factor in a salesroom. The salesroom itself is a quantity to be reckoned with. The most successful merchants employ high-paid decorators to display their wares. This display feature of automobile salesmanship has scarcely been scratched. How many salesrooms can you find in which the laws of display have been studied out to the smallest detail? There are a few of such in every big city, but they can generally be counted on the fingers of one hand. Above all, the salesroom should be well lighted, it should be orderly, it should be clean, and the salesmen should be in keeping with the situation. The public of to-day is a critical public; it is accustomed to the finest arts of salesmanship in such fields as insurance, bonds, stocks, real estate, debentures, etc., and when the amateur automobile salesman tries to create an impression it frequently resents it. It does not remonstrate, but simply does not buy.

One of the largest automobile concerns in the country has realized that not only must its salesmen know its own cars, but they must know all about the car of its leading competitor. At one of its conventions a car of its leading rival was purchased and analyzed in every detail. The salesman thus became acquainted with its good qualities as well as with its defects. In this way he became better qualified to meet the arguments of the buyer. Nothing is quite so convincing as an array of facts when it comes to making a sale. The more the salesman knows about the other car, the more confidence he has in himself, the more convincing are his statements, and the more weight they have with the buyer. Knowledge is not the only essential, but it is a big factor. In addition to knowledge the salesman must know how to address people; he must have ability in studying his buyer; he must know the logic of arguments; he must have address, and must know his car thoroughly.

Knight a Guest of His Associates

CHARLES Y. KNIGHT, inventor of the Knight sleeve-valve motor, was the guest of honor at a dinner given Monday night at the New York Athletic Club. There were about 100 present, including representatives of the four licensees in the United States under the Knight patent and a representative gathering of automobile officials. Mr. Knight arrived in New York on the *Campania* last Saturday and will remain in this country only a short time. He is booked up for a number of addresses and lectures in various parts of the country and his itinerary as marked out so far will extend to Pittsburgh and Cleveland and may extent still further west.

During the speeches that followed the elaborate dinner the hitherto unwritten history of the invention was outlined by Mr. Knight and Messrs. Lonas and Kilbourne, who were associated with the inventor in developing the device and placing it upon the market.

Mr. Knight told the story of his life in simple, direct fashion. He said he was born in Indiana and entered the battle for a living as a printer. He progressed through the whole range of the craft and at the end of 25 years was editor of a weekly produce paper in Chicago. During his service in the publishing line he invented a newspaper printing press and a wrapping device, neither of which gained him much fame, and he experienced two rather discouraging collisions with competitors who infringed patent rights he thought he was entitled to.

At the time of the commencement of the vogue of the automobile Mr. Knight became interested in the new art and purchased one of the earliest examples of the industry that was shipped to Chicago.

Charles Y. Knight, inventor of the Knight sleeve-valve motor

In the fall of 1907, having gained the ear of the Daimler Company, in England, the motor was accepted by that concern and within the next year was placed with representative concerns in other European countries.

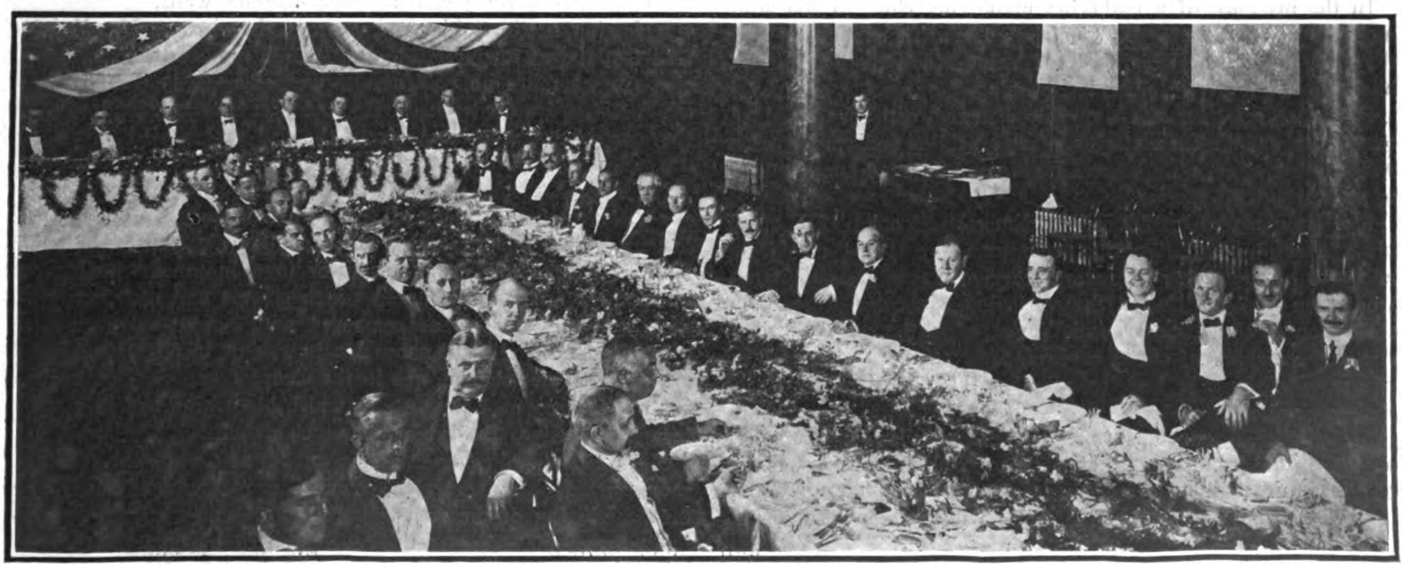
With regard to its introduction in the United States, Mr. Knight recounted his experience with four prominent automobile manufacturers. He said he had arranged for licensing the four, when a reissued patent covering steam engines was injected into the situation and two of the companies, having gained certain interests in the reissued patent, which Mr. Knight said was written with a model of his engine as its foundation, declined to proceed under the license and threatened Mr. Knight with action in infringement if he attempted to manufacture his own engine in the United States.

This proved effective in stopping the disaffected pair of manufacturing concerns from taking up the device at the time and served as a check upon the activities of the Knight motor in America until this year.

Mr. Knight said that Mr. Kilbourne, his partner and financial backer, had spent $150,000 before there was any substantial return from the business.

Mr. Lonas acted as the attorney for Mr. Knight during his early struggles and was instrumental in paving the way for the first real trial of the motor at the hands of the Daimler company.

One of the most interesting



Charles Y. Knight was honored by his associates at a banquet held at the New York Athletic Club on Monday evening, Sept. 26

features of the speaking was the attitude assumed by the American licensees. Horace De Lisser, vice-president of the United States Motor Company, said that about 40 per cent. of the number of cars authorized under the licenses granted to the Columbia and Stoddard-Dayton companies had been contracted for and the Columbia company desired to make 100 per cent. more than its allotted number and the Stoddard-Dayton, 75 per cent. more, for 1912 business.

C. E. Hadley, production manager of the Knight engine department of the Stearns company, said that the engine after a series of exhaustive tests had proven satisfactory and that 40 cars had been finished.

Mr. De Lisser created something of a sensation when he spoke of the part that is to be played in the making of Knight engines in the United States by the Atlas Engine Works, of Indianapolis. He said that, while he had no doubt as to the quality of work to be turned out by the engine company, he wished to warn Mr. Knight that there is real danger to be feared if the engines so made should get into the hands of automobile manufacturers who do not realize that there is anything else in an automobile beside the engine.

He said that, in such an event, it might reflect upon the licensees who manufactured their own Knight engines.

Replying broadly to Mr. De Lisser, H. J. Halle, treasurer of the Atlas Engine Works, assured the licensees that their interests would be jealously guarded by his company and that every precaution would be taken to prevent the engines made by his concern from getting into undeserving hands.

He explained that the Atlas Engine Works had secured the fourth American license from Mr. Knight and that the company would make all the Knight engines in the United States that were not made by the other licensees. He broadly intimated that the activities of his company might not be permanently limited to such work, but that, if in the future the licensees wished the Atlas company to make their engines, the company would undertake to supply the whole licensed automobile trade in the United States.

Other speakers were: J. G. Sterling, of the Stearns engineering department, Frederick E. Dayton, of the Columbia, and others. J. E. G. Ryan acted as toastmaster. Those present included the following:

Charles Y. Knight, L. B. Kilbourne, Frank E. Lonas, H. W. Nuckols, Horace De Lisser, Alfred Reeves, Henry Sanderson, F. H. Baker, H. H. Hower, W. A. Lesser, C. E. Hadley, J. G. Sterling, E. G. Moore, Andre Massanet, E. Lilly, James M. Carples, Coker F. Clarkson and many others.

Knight Explains His Engine

In the presence of a gathering numbering close to 400 automobile experts, Charles Y. Knight explained in exhaustive style the operation of the Knight Sleeve-Valve Motor at the Automobile Club of America, Tuesday evening.

For over an hour the assembly listened with profound attention to the inventor's address and at the end, the speaker was questioned on a number of points and devoted another hour to answering the queries.

Mr. Knight was introduced by Emerson Brooks. He began his address by outlining the preliminaries that led up to the adoption of the motor by several foreign companies and its introduction into the United States, laying particular stress upon the action of the Atlas Engine Works, which he said had abandoned the making of steam engines, after 50 years of successful operation along that line, to take up the manufacture of the Knight engine.

He said that the conclusions to be drawn from this action are that this company believes that the reciprocating engine of the future will be of the internal combustion type and that the ultimate internal combustion motor will not be of the poppet-valve variety.

In describing the present state of the art insofar as internal combustion engines are concerned, Mr. Knight said that the field is divided into two parts; one the poppet-valve school and the other the four-cycle sleeve-valve motor. He minimized the importance of the two-cycle engine for automobiles, saying that that principle had been employed with success in one instance, but that the public was not enthusiastic. He stated that public taste was difficult to follow, but that it was a most important influence.

In emphasizing the effect that the introduction of the sleeve type has had upon the art he said that at least 250 patents have been issued abroad covering suggestions for improvement of the sleeve-valve engine, none of which varies materially from the Knight device.

In telling of the salient features of his invention, Mr. Knight said:

"The outstanding feature is the substitution of sleeve valves for poppet valves, which idea I believe was wholly original with myself. Other forms of valves than mine, instead of contributing to further efficiency of the motor, are employed in spite of their disadvantages.

"The ports in the inner sleeve are sealed in operation through the lapping of their openings with a wide ring, called the junk ring. This ring is similar in construction to the ordinary piston ring, only wider in order to seal the ports. Under the junk ring is placed a second to insure perfect contact with the interior of the sleeve. Above them are two or three ordinary piston rings to bar the escape of gases which might pass the break in the junk ring.

"At the time of explosion the ports in the inner sleeve are central with a wide junk ring. Hence at the time of the development of the greatest heat, the ports are not exposed to heat at all and therefore the lips and the section of the sleeve carrying them are cooled after every explosion, being pushed up and rubbed against a water-cooled surface."

Mr. Knight pointed out that in the case of poppet valves, the heads are always subjected to the highest temperature generated in the explosion chamber, which he said at the maximum was approximately the melting point of steel.

He then described in much detail the system of lubrication used, dealing with the difficulties encountered in this phase of the operation of all motors and stating that in the Knight engine the problem had been solved in a satisfactory manner. He brought out the fact that only on the compression stroke was their heavy pressure on the sleeves and that in consequence of the relaxed pressure on the other three strokes, the flow of oil over the lubricated surfaces of the sleeves and cylinder was comparatively easy to accomplish. This he said was by splash at the bottom and by capillary attraction at the top.

The clearance between the sleeves, he said, may be as great as that between the piston and the cylinder walls.

Referring to the subject of wear in the sleeves, Mr. Knight said that it was inappreciable and that in motors that had traveled 100,000 miles no evidence of wear was to be found after the first few hundred miles. He said that he was confident that they would not deteriorate from the use represented by 1,000,000 miles on the road.

He made a special point about the accessibility of the sleeves for cleaning or the removal of carbon deposits. The power lost in driving the eccentrics which actuate the sleeves, he said, he found to be about 2 horsepower in a motor developing 77 horsepower and using a dozen 5-inch sleeves and reckoned that the proportion of loss as compared with poppet-valve engines of similar size would be about 160 to 250, or in other words, 50 per cent. greater than it was in the sleeve type.

He then recounted the tests to which his engine had been subjected, going into the subject in much detail.

Mr. Knight used a huge working model of a sectional cylinder, showing the piston and sleeve action, eccentrics and shaft and the functioning of the ports.

The questions asked at the conclusion of his address did not bring out anything radical or particularly interesting.

S. A. E. Tour Abroad

PROSPECTS are good for the size and success of the trip the members of the Society of Automobile Engineers will take abroad during November, to view the Automobile Show at Olympia, London, and leading automobile factories in England and France, and to participate in meetings with the Incorporated Institution of Automobile Engineers. November 11 the British Society of Automobile Engineers will give the S. A. E. visiting members a dinner, and November 8 there will be a joint technical meeting, at which a member of the society will present a paper.

In addition to events previously announced, visits will probably be made to the South Kensington Museum in London, the testing laboratories of the Royal Automobile Club of England and of the Automobile Club of France, the Conservatoire des Arts et Métiers, and the Clement and DeDion plants in France. Factories making commercial vehicles as well as pleasure cars will be visited; also those having moderate-priced as well as highest-priced product.

The party will probably sail on a steamer leaving New York November 1, and the program outlined will take up practically the whole month of November, including the return journey home.

The following have signified their intention of making the trip; many of them will be accompanied by their wives: Henry Souther, president of the society; Howard E. Coffin, past president of the society; D. G. McDiarmid, superintendent and designer, C. P. Kimball & Co., Chicago; William E. Metzger, secretary and treasurer, Metzger Motor Car Co.; William Kelley, vice-president and engineer, Metzger Motor Car Co.; J. G. Vincent, chief engineer, Hudson Motor Car Co.; A. R. Miller, Bartal, Daly & Miller; John S. Clarke, vice-president, Autocar Co.; B. B. Bachman, engineer, The Autocar Co.; David S. Ludlum, president, Autocar Co.; G. R. Wadsworth, assistant to president, Peerless Motor Car Co.; A. J. Myers, engineer, G. & A. Carbureter Co.; G. B. Von Rottweiler, manager and chief engineer, Falls Machine Co.; H. L. Davisson, engineer, Edison Storage Battery Co.; L. C. Marburg, secretary and treasurer, Marburg Bros.; Coker F. Clarkson, secretary, Society of Automobile Engineers.

Quite a number of additional members will join the party if they can make the necessary arrangements.

Membership in the Society of Automobile Engineers is still growing steadily and rapidly, the present figures for all classes being 934, of which about 700 constitute the full active roster. The growth of the S. A. E. has been phenomenal. Less than 18 months ago it had no more than 300 members on its membership rolls.

This growth is particularly accountable to three factors: First, the absorption of the mechanical branch of the A. L. A. M., which nearly doubled its membership; second, the rapid growth of the automobile industry; third, the active, useful work of the society itself.

The field from which it has drawn its members is limited, but the scope from which it may rightfully draw them is constantly increasing. There are probably 1000 fully qualified engineers employed by the manufacturers of cars. There are at least another 1000 employed by manufacturers of automobile accessories and quite as many independent engineers of high attainments who act in a consulting capacity for both car and accessory makers.

In addition to these men, all of whom possess a highly technical training, there are many thousands of corporation officers, students of mechanics and men of practical knowledge connected with the industry who are eligible to consideration in the limited grades of the S. A. E. Naturally enough the society is thriving from a membership point of view, just as the industry it represents is growing in importance, not only as a factor in the progress of the day, but also as a potent force in the general advancement of civilization.

Gossip of Coming Shows

DURING the past week slow progress has been made with reference to the two big automobile shows to be held in January. With regard to the space allotments at Madison Square Garden during the exhibit of pleasure cars, the probabilities are that there will be only a few minor changes, but in the truck section the Automobile Board of Trade is in a quandary.

The management is endeavoring to locate the various exhibits approximately as they were staged last year but owing to the pronounced tendency of many of the companies to make larger trucks than before the problem of housing exhibits above the main floor is proving a puzzle.

The difficulty lies in the inability of the elevators to handle the largest types of trucks. Thus, where a concern that formerly showed small cars in the gallery, and this year wishes to display big ones, something will have to be done to make it possible.

The National show, scheduled for the Palace, is making good progress. Already contracts have been made to display the Regal, Waverley, Imperial, Stutz, Abbott, Cole, Crow, Firestone-Columbus, Elkhart, Colby, Great Western and Rambler among the pleasure automobiles and the Sanford-Herbert, Cortland, Federal, Lippard-Stewart and Universal, among the commercials. In addition to these, contracts have been practically closed with the Kissel, Schacht, Lion, Hupmobile, Clark-Carter, Paige-Detroit, and the Hupp Corporation. There will be a fine exhibit of electrics including Baker, Babcock, Rauch & Lang and Detroit.

It is announced that fully forty makes of pleasure cars are likely to be shown and probably twenty different types of trucks.

Straightening Out Halladay Tangle

CHICAGO, ILL., Sept. 26—Last Saturday a petition in voluntary bankruptcy was filed by the Streator Motor Car Company, of Streator, Ill., and also John C. Barlow and Paul Chubbuck, the principal owners of the company. About 2 hours later one of the creditors of the company presented a petition for the appointment of a receiver and the Central Trust Company was appointed by Judge Landis.

Yesterday the Streator Motor Car Company, in a petition, joined in by its principal creditors, asked that the order appointed by the receivers be vacated, and the matter was continued until to-day. Judge Landis, after hearing the case, decided to remove the receiver.

It developed during the hearing to-day that the Streator Motor Car Company had been doing a large business on a small capital and was very hard pressed. Mr. Barlow and Mr. Chubbuck, its chief stockholders, owned large real estate holdings in and around Streator but could not quickly realize on the property, so as to assist the company.

In this condition they approached the larger creditors of the motor company with a proposition to bond their real estate holdings for $425,000 and give the bonds to the creditors of the company in payment of its debts, this putting the company on its feet financially. About 80 per cent. of the creditors in number and amount accepted, but a small minority was trying to block the proposed settlement and the result was the filing of the petitions in bankruptcy.

It was the first case presented in this jurisdiction under the amendment of the bankruptcy act in 1910. The petitioners did not ask to be adjudged bankrupt, but simply that a meeting of their creditors be called to prove up their claims and that at such meeting, they proposed to submit to the creditors the proposition of accepting the bonds in payment of their claims against the motor company, under the amendment referred to.

It is understood that a meeting of the creditors will be called in about 10 days. While no formal statement has been made, it is claimed that the Streator Motor Car Company has assets of about $750,000 and owes some $300,000. The proposed plan will put the company entirely out of debt. In the meantime it will operate as heretofore.

Flathead Motor Club celebrates completion of a section of the Glacier Park-Yellowstone Park road with a delightful tour

Montana Building Inter-Park Road

KALISPELL, MONT., Sept. 22—Good roads do not necessarily follow in the path of settlement and territorial development, but may be the forerunner of the upbuilding and populating of a hitherto inactive area. This has been demonstrated by Flathead County, Montana, which, a few days ago, celebrated the opening of a 30-mile automobile boulevard where a few months ago had been only a rough Indian trail through the forest. This road, when completed, is destined to bind Yellowstone Park and the Glacier National Park, 300 miles apart as the crow flies.

In honor of the opening of Flathead County's section of the road a band of motorists from Kalispell, Mont., with 50 cars in line, toured from their town to the Glacier National Park for inspection of the new highway.

The start was made under the cloudless skies of a perfect September day, with just a tang of approaching autumn in the air. The run was planned by the Flathead Motor Club to celebrate the completion of the road across that county.

M. W. Bottorf, in a 48-horsepower Franklin, was pacemaker. Falling in behind him the automobiles wound through a valley road to Columbia Falls, and a few miles out of town many had their first introduction to the great improvement made within the past year. Stumps had been removed, curves cut out and the roadbed graded and rolled.

From Columbia Falls the way led across a bridge over the Flathead River, and at the top of the hill the cars stopped in a long line which extended back through the valley between tall and stately pines.

Through picturesque Red Rock Canyon, with the blue Flathead River at the left and at the right a precipitous mountain, where a couple of years ago the old passage was by foot or horseback, the procession wound round on a shelf cut out of the mountain side. It was nearly all new country, except as it had been seen from passing railway trains. The trees stand thick and straight on either side, 100 feet high, and in places the road is a great gash through the forest.

The transformed "tote road" led on, with varying scenery, to Lake Belton, where some of the travelers stopped for lunch, the others traveling three miles farther to Lake McDonald.

The building of this highway may be an important argument for the admission of automobiles to Yellowstone Park, where they are now forbidden by the Government.

The building of the Flathead County part of the road was considerably criticized by those who failed to see the object in building a road through a rough forest country. Other sentiments, however, prevailed and the construction was pushed rapidly forward with the result that Flathead County, Montana, is now a much-talked-of section of the Northwest, while it has, by this highway, opened its towns and its territory to the travel of motorists of the whole United States.

Good Roads Convention November 20-23

RICHMOND, VA., Sept. 25—The National Good Roads Convention which will be held in this city on November 20-23 and which President Taft has given assurance he will attend, will be extensively advertised throughout all the States through the Washington office of the association.

The most important matter to be taken up at the convention will be the construction of the national highway between Richmond and Washington as a memorial to President Lincoln at a cost of $2,000,000.

Various plans for the "capitol to capitol" route have been suggested. Charles P. Light, chief field representative, is in Richmond making the final preparations for the national convention.

Government Instructs in Road Examination

WASHINGTON, D. C., Sept. 25—Dust prevention and road preservation are almost inseparable subjects in the study of good roads, so insistently demanding the attention of road engineers and chemists interested in modern road construction. The bulletin just issued by the Office of Public Roads, Department of Agriculture, on methods for the examination of bituminous road materials, containing complete descriptions of the methods of examination for that class of materials, as employed at present by that branch of the Government service, will undoubtedly materially further the adoption of standard methods, a matter of the utmost importance at this time, different methods frequently obtaining in the same State.

These methods are presented in such a form that any intelligent person may, with a little practice and the proper equipment, make such examination. It is to be regretted that no standard methods for examining bituminous road materials have been generally adopted, as the necessity for such standards has become imperative. The Office of Public Roads has given considerable attention to the matter.

Maryland Seeks to Amend License Law

BALTIMORE, MD., Sept. 25—A resolution was introduced into the City Council by Councilman Garland which directed that the joint special committee on legislation of the two branches of the Council during the next session of the Maryland Legislature be empowered to draft amendments to the motor vehicle law regarding the issuing of licenses.

These proposed amendments call for the appointment of a reliable board of examiners to whom all applicants for licenses to operate motor cars shall submit their claims and qualifications.

Councilman Garland's aim is to have licenses withheld from all persons except those who, in addition to possessing the proper skill, are sufficiently cautious in their habits and not a menace to the general public. Furthermore, Mr. Garland desires to have a provision inserted making it punishable for any one to operate a motor car unless he is an actual licensee in his own name; also that the city of Baltimore shall receive a volume of revenue from automobile licenses in exact proportion to the number of automobile licenses granted to residents of the city.

Service Cars at Municipal Congress

CHICAGO, Sept. 25—Motor cars are in evidence in the Coliseum this week during the International municipal congress and exposition now in progress here. More than half of the public service vehicles on display are motor driven. Among the exhibitors are the Briggs Labor Saving Specialty Co., the Kelly-Springfield Road Roller Co. and several makers of motor fire-fighting equipment.

Good Roads, Keynote of Prosperity

(Continued from page 519.)

The cost of some of the best present work runs as high as $16,000 a mile and the average of first-class road making is probably in the neighborhood of $10,000. If general highway construction all over the country were to reach such figures the total expenditure would be considered prohibitive. But while general improvement on any such basis is still a long way in the future, it will arrive one day and the United States will wonder why there ever should have been a doubt about the wisdom of a permanent investment of ten billions of dollars in country highways.

It will not come in any one year and will not be completed in any one decade; thus the expenditure will be spread over many years and the returns will be so quick to follow investment in any locality that the stupendous amount of money involved will not prove burdensome. The investment of vast sums of money in road improvements will not serve to divert the wealth of the country from the ordinary channels of trade, for, while the highway bonds will undoubtedly attract conservative investors, the proceeds of the bonds will be spent for labor and material and in the course of ordinary business will be immediately drawn back into the commercial veins and distributed to the arteries of the business body.

There is no chance to overstate the importance of good roads. There never was a safer and better investment for the taxpayers of any township, county or State than the fully justified reputation for having excellent highways. It means more trade and better trade; more health and human enjoyment; more social pleasure and business facility. It means in a word, to the general citizenship, a life worth living.

Maxwell Scores in Lu Lu's Run

PHILADELPHIA, Sept. 25—Eighty-six contestants appeared for the first social run of the Lu Lu Temple Automobile Club from Philadelphia to Atlantic City last Saturday, making one of the largest organized tours ever held in the East.

Four prizes were awarded to the contestants who arrived in Atlantic City nearest to the secret time schedule set by Potentates W. Freeland Kendrick and Harry Evans. The winner proved to be a new Maxwell Special entered and driven by William A. Walton. A Maxwell Messenger 16-horsepower runabout, driven by A. A. Jones, won fourth place. At the end of the run an automobile show was held on the Million Dollar Pier which was attended by thousands.

A great gash cut in the primeval forest to accommodate the road from Glacier National Park to Yellowstone Park.

Late News from the Contest World

HARTFORD, CONN., Sept. 29—A bursting tire robbed Ralph DePalma's Simplex of an opportunity to snatch the 15-mile circular track record at Charter Oak Park yesterday afternoon. Taking the turn at the eighth-mile post at a mile-a-minute gait, the tire burst and the car skidded to within a foot of the fence.

The trial was the climax of the race meet held under the direction of the Automobile Club of Hartford before a crowd of 5,000 people. The DePalma-Simplex combination was the chief attraction. He went after the one-mile record and failed, covering the distance in 52 1-5 seconds, the record being 51 3-5 seconds. Later he went after the Charter Oak Park record for five miles and succeeded, his time being 4 minutes and 23 seconds, 1 2-5 seconds faster than the record.

There was a special race between three Motorettes, the three-wheeled car built in Hartford. It was intended to make it a five-mile affair, but after one mile had been completed it was announced that another would finish it. The winning car covered the two miles in 5:14 2-5. DePalma then brought out his Simplex to go after the five-mile record, and he won.

The event for non-stock cars, Class C, Division 3 C, 231-300 cubic inches, for five miles was won by DePalma, driving a Mercer, in 5:19 1-5; Brainard, in a Cole 30, getting second place, and Beach in a Mercer third. DePalma won first in a five-mile free-for-all in a Mercer, with Brainard second and Beach third.

A parade of 1912 cars and various gymkhana events completed the program. The summaries:

Position.	Car	Driver	Time
Record Trial, 1 Mile—(Record, 0:51 3-5)			
	Simplex	DePalma	0:52.20
Record Trial, 5 Miles—(Record, 4:24 2-5)			
	Simplex	DePalma	4:23
Non-Stock, Class C, 231-300 Cubic Inches			
1.	Mercer	DePalma	5:19.20
2.	Cole "30"	Brainard	5:44.80
3.	Mercer	Beach	5:54
Non-Stock, Class D, Free-for-All, 5 Miles			
1.	Mercer	DePalma	5:14
2.	Cole "30"	Brainard	5:33
3.	Mercer	Beach	5:40
15-Mile World's Record Trial			
	Simplex	DePalma	Unfinished

Lee Oldfield Held Without Bail

SYRACUSE, N. Y., Sept. 23.—Lee Oldfield, whose racing machine crashed into the crowd at the State Fair grounds last Saturday and killed 11 persons, appeared before Coroner George R. Kinne yesterday to testify to conditions leading to the accident. Though for several days his nerves were totally unstrung, and at one time the hospital attendants feared for his reason, he was much improved yesterday, though much affected while giving testimony. At the inquest Oldfield gave his age as 22, his residence as Wilkes-Barre, Pa., and stated that he was married and had an infant daughter. The driver placed two licenses in evidence to show that he was considered competent to pilot a car. The tire that burst and caused the accident was thoroughly examined, there being a gash of almost a foot in the shoe and a rent of about equal length in the inner tube. Oldfield admitted it was worse than he realized, but said that such a condition might exist on the inside and yet have the outer tire apparently sound.

In regard to the moot question of whether Oldfield was signaled to hit up speed, he said his manager, Mr. Moross, signaled him to that effect after completing his thirty-ninth mile. Till then he had been shutting off his power right after leaving the grand stand, to make the turn in safety on the mile course; but after getting the signal he went as far as the bend without shutting off the power. He testified that the tire that burst was the one that was getting the most strain, being the first to hit the embankment on the cut across.

Bail was refused for Oldfield, he being under technical arrest. The inquest will be continued and is certain to be exhaustive. Meanwhile, Oldfield is under the surveillance of a plain clothes man while at the hospital. He expects in a day or two to remove to a hotel.

Preparing for Fairmount Park Race

PHILADELPHIA, Sept. 23—Active preparations are under way by the Quaker City Motor Club for the fourth annual Fairmount Park road race to be held on Saturday, October 7. Steam rollers, watering carts and a gang of men are at work daily getting the course in ship shape, and in order to have the roadway in as perfect condition as possible, there will be no letup in the work by the organization until the day of the race.

As was the case last year, the proceeds from the sale of seats and parking places will be donated to various charitable organizations.

The entries at present time are: Lozier, to be driven by Ralph Mulford, runner-up last year; Len Zengle, who won the event last year with a Chadwick, will drive a National in the coming race; National, Donald Herr; Fiat, Lee Oldfield; Case, Joe Jagersberger, and Stutz, G. Anderson.

Glidden Tour Has 61 Entries

There are now 61 entries filed for the Glidden Tour. Those entering during the past week are as follows: L. C. Brown, Athens, Ga., Mitchell; P. D. Sandlin, Jasper, Fla., Cadillac; Bishop and Varner, Athens, Maxwell; J. J. Howard, Jacksonville, White; L. C. Denmark, Jacksonville, Cadillac; R. S. King, Arcadia, Fla., Cadillac; Carolina Portland Cement Company, Atlanta, Ford; E. M. Willingham, Atlanta, Ford; J. O. Teasley, Alpharetta, Ga., Ford; C. A. McCardle, Indianapolis, E-M-F; and Athens Motor Company, Athens, Columbia.

Coming Contests on Track and Road

NEW YORK CITY—What may prove to be the last track races to be seen in the Metropolitan district this season will be staged at Guttenberg, N. J., on Saturday afternoon. The card contains 4 dashes at five miles and 2 at ten miles for non-stock cars. Second money is offered in all the events.

OMAHA, NEB., Sept. 25—The Omaha Speedway Association will pull off a series of four days' racing on next Saturday, September 30, Sunday, Monday and Wednesday. Men have been at work on the track improving it and building better fences, but this will all be completed before Saturday. There will be a 50-mile event each day, with shorter races. The Ak-Sar-Ben festivities will bring large crowds into the city.

SAN FRANCISCO, Sept. 23—An international automobile race in Golden Gate Park, in this city, on Washington's birthday, February 22, next year, is the plan of the publicity committee of the Panama-Pacific International Exposition Company.

OKLAHOMA CITY, OKLA., Sept. 23—The 800-mile route of the *Daily Oklahoman* reliability run of 1911 will start on October 12. The entries will include not less than sixty cars.

Trade and General News High Lights

DETROIT, MICH., Sept. 25—In reply to the injunction bill filed by the Hupp Motor Car Co., R. C. Hupp, of the Hupp Corporation, maker of the new R. C. H. car, made the following statement:

"In view of the pleasant relations which have always existed between the Hupp Motor Car Co. and myself, I am very much surprised, indeed, to hear of this action. They have known for several months of my intention to place upon the market a new gasoline car, to be handled by the Hupp Corporation.

"In the naming of the new car, I was careful to avoid choosing a name that would conflict in any way or tend to injure the business of the Hupp Motor Car Co., and, although the name 'R. C. H.' is my own initials, it does not seem to me there is anything in the name of the new car to which to take exception.

"As for the Hupp Corporation, it is a combination of five large automobile parts plants, organized several months ago, consisting of a large foundry, drop forgings plant, machine shops, electric and gasoline car assembly plants. For nearly a year we have been engaged in the manufacture of automobile parts and in the building of electric and gasoline cars, including the Hupmobile, and in all that time there has never been a word of objection from anyone to the use of the name 'Hupp' in connection with our business. All the castings and forgings and machine parts in the Hupmobile are made, and the final assembly and shipping of this car is done at this plant.

"We have one of the most completely equipped automobile factories in the world, with a capacity of 60 cars a day, and, with the additions contemplated, we will increase this capacity by nearly 50 per cent.

"The Hupp Corporation was named for my brother, L. G. Hupp, who was in active charge at the outset. Since severing my connection with the Hupp Motor Car Co., in August, I have been devoting my entire time and attention to the affairs of the Hupp Corporation. Neither my brother nor myself, nor anyone by the name of 'Hupp' is now connected with the Hupp Motor Car Co. We have notified the Hupp Motor Car Co. that we shall be unable to manufacture any more parts for their cars after November 1. We are planning to market 10,000 new R. C. H. cars during the season of 1912, and our facilities here will be taxed to the limit in turning out our own product."

Atlanta Automobile Row Is Growing

ATLANTA, GA., Sept. 25—Eleven makers are represented in Atlanta by branch houses or by concerns that amount to that. Here is the list: Overland Southern Motor Company, United Motor Atlanta Company (Maxwell, Columbia, Sampson, Stoddard-Dayton and Courier), Mitchell-Lewis Motor Company (Mitchell), J. I. Case Threshing Machine Company (Case), Ford's Southeastern branch, Corker Motor Car Company (in effect a branch for the Haynes, also carries the Matheson), Stearns Southeastern branch, Southern branch Buick Motor Company, Southeastern Studebaker branch (E-M-F and Flanders).

In addition to the eleven branches, the Gate City of the South has eleven active agencies, most of which are housed in their own places of business with garage accommodations. These are: Krit Motor Atlanta Company, Cole Motor Company of Georgia, Steinhauer and Wight (Cadillac), Scott Motor Sales Company (Pathfinder), Central Auto Supply Company (Imperial), John M. Smith (Pierce-Arrow), Fulton Auto Supply Company (Peerless, Marmon, American and Gramm), E. D. Crane and Company (Hupmobile and Columbus Electric), Clifford V. Anderson (Corbin), Northcutt Company (Chalmers), W. M. Leathers (Dorris), The Auto Company (Thomas, Alco, Oakland), Herman J. Haas (Winton, Rauch & Lang Electric).

Automobile Eases Rigor of Car Strike

DETROIT, MICH., Sept. 25—Detroit experienced a little object lesson last week that fully convinced everybody that the motor car is a public necessity instead of being merely a luxury. Without warning, Wednesday morning, the city found itself with a street car strike on its hands, the first in 20 years. Not a wheel turned for the purpose of carrying passengers all that day, and yet, thanks to the motor car, citizens were not seriously discommoded. There was considerable confusion in the early morning hours, but toward noon things were running along fairly smoothly. Factories were running as usual, though shorthanded in many instances. The downtown stores were well patronized, and even the theaters did a good business.

The worst sufferer, perhaps, was the State Fair management. But for the automobiles, the fair would have been deserted and there would have been nothing left to do but to close down. Motor 'bus lines were quickly established, however, and the fair was well patronized in spite of the high tariffs exacted by the enterprising 'busmen.

Cincinnati Dealers' Used-Car Scheme

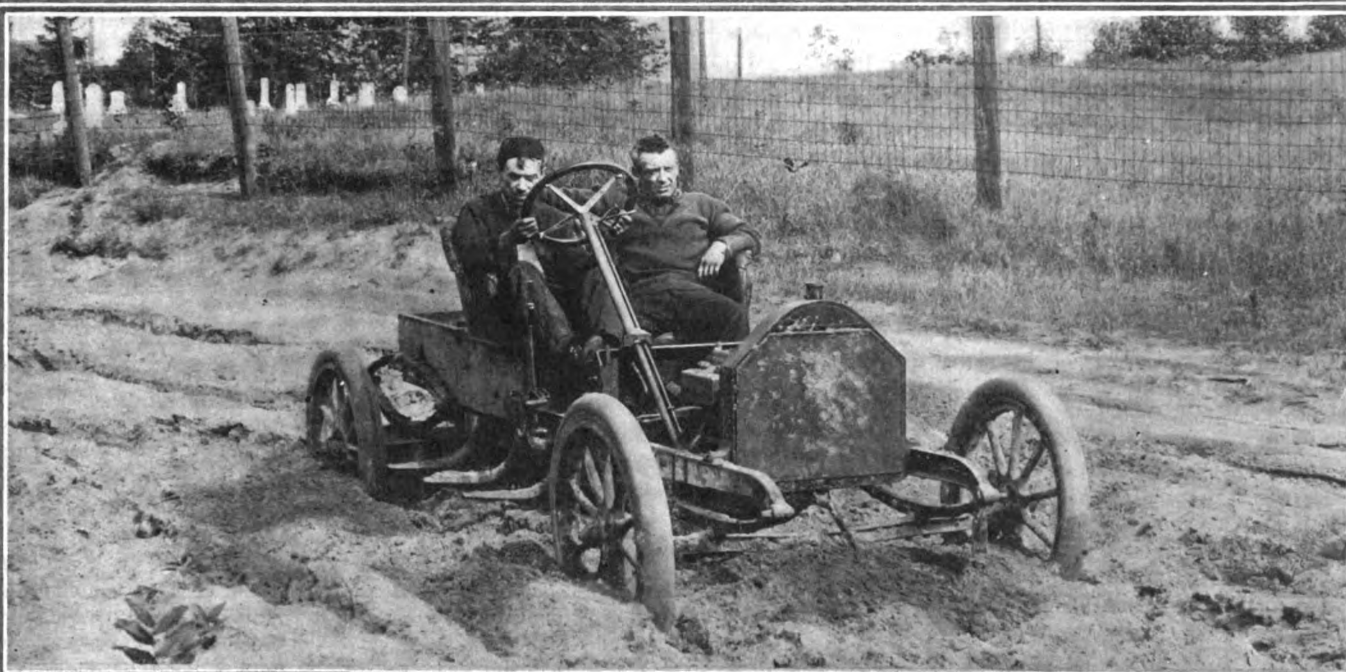
CINCINNATI, Sept. 25—The details for a new system in the trading of broken down and second-hand machines, in part payment for a new automobile, are being put in practical shape for operation here. It will be under the auspices of the Cincinnati Automobile Dealers' Association, and probably operated by the association itself.

The proposition is to establish a general clearing house for second-hand and broken-down cars, with an efficient and independent general manager and corps of expert mechanics. The machines are to be put in first-class order and placed on sale at the expense of and for account of the owner, thus obviating present abuse of legitimate competition in fixing values on them. Under such an arrangement the dealer would not need to fix the price on the machine to be traded, the association to assume that responsibility, together with its repair and sale.

Saurer and Mack Companies Combine

CHICAGO, Sept. 25—The International Motor Co., with headquarters in New York City, is the title of a new holding and sales company formed by the interests controlling the Saurer Motor Co. and the Mack Brothers Motor Car Co., of which C. P. Coleman, president of the Saurer company, is at the head. The International only was formed last week, and so far there has been no announcement as to the officers or the capitalization.

The organization of the International company marks a departure in commercial motor vehicle circles in that it brings together the Saurer and Mack interests. The new concern, it is said, will act as a sales agent for the two lines of trucks, the idea being that both will save in the expense of marketing their product without in any way interfering with the methods of the two companies as at present constituted. Each will retain its individuality, but the two lines will be marketed by the International company. The combination gives a line of American-made trucks that extends from 1 to 7 tons inclusive.



News of the Week Condensed

DETROIT, MICH.—The testing out of chassis before they are finally passed upon by the factory experts is carried to the extreme at the Everitt plant. The chassis are put through a stretch of deep sand on high gear, and unless they perform satisfactorily the inspection department refuses to O. K. them.

BUTTE, MONT.—Meritt & Riley have been signed up by the Franklin Automobile Company as dealers for the coming season, succeeding The Butte Novelty Works.

NEWARK, N. J.—The Johnson Auto Conveyance Company has been established here. The company now employs four Johnson trucks for its freight carting business.

BOSTON, MASS.—Harold D. Bornstein has been appointed manager of the New England branch of the Velie Motor Vehicle Company, with headquarters at 92 Massachusetts avenue.

WASHINGTON, D. C.—E. C. Bull has been appointed manager of the Pope Automobile Company, agent for the Oakland and Pope-Hartford. Lawrence Schenk has been made manager of sales.

BOSTON, MASS.—George E. Stuart, deputy street commissioner of Newton, is being considered as the successor of Chairman Harold Parker, of the Massachusetts State Highway Commission, now that the latter has sent in his resignation. Mr. Stuart is a practical road builder, having been connected with the street department of Newton for many years.

PHILADELPHIA—The South Jersey Motor Club will hold a race meet on the fair grounds half-mile track at Bridgeton, N. J., next Saturday. So far twelve cars have been entered.

MERIDEN, CONN.—The Connecticut Telephone and Electric Company and the Connecticut Shock Absorber Company have opened a joint branch at 819A Boylston street, Boston, Mass.

NEW YORK—The Pope-Hartford Automobile Company has taken over the business of the Pope Motor Company of Jersey City. B. F. Ellsworth will have charge of the new office.

MILWAUKEE, WIS.—H. W. Ellis, of Chicago, will hereafter head the sales department of the Johnson Service Company's automobile department here. Mr. Ellis is a new man in the automobile field.

FINDLAY, OHIO—At a Fall festival at Defiance this week forty automobiles paraded for prizes. The first prize lay between Mayor Chenevert and Glen Coy, but a flip of the coin gave it to the Coy machine.

BALTIMORE, MD.—The D. C. Walker Automobile Company has become the Baltimore representative for the Stearns Silent Knight. The company expects to receive the demonstrator within the next few days.

YORK, PA.—Harry R. Pfeiffer, 537 West Market street, has taken the agency for the Stoddard-Dayton automobiles. Mr. Pfeiffer has the sole agency for the Baker Electric for York, Adams and Lancaster counties.

OTTAWA, CAN.—The first annual automobile and motor boat show to be given at Ottawa will be staged from April 6 to 13, 1912, at Howick Hall, under the auspices of the Ottawa Valley Motor Car Association.

HARRISBURG, PA.—The Fall sociability run of the Motor Club of Harrisburg was held last Thursday to the Allentown fair. Secretary of the club, J. Clyde Myton, laid out the route to Allentown which is about 93 miles. A dozen cars were entered in the run.

INDIANAPOLIS, IND.—Nordyke & Marmon Company has entered four cars in the Santa Monica races to be held on the great California course on October 14 according to an announcement made from the factory.

BALTIMORE, MD.—The Lambert Automobile Company is preparing to occupy new quarters at Mount Royal and Maryland avenues. The company handles the Maxwell, National and Hudson cars in Baltimore and vicinity.

DETROIT, MICH.—Harry Grant will drive the Lozier car owned by Dr. W. H. Chambers in the Fairmount Park road race October 7. Grant will act as a member of the Lozier team despite the private ownership of the car.

BALTIMORE, MD.—The Automobile Company of Maryland, agents for the Kissel Kar and truck in this city and the State of Maryland, has moved its quarters from the Academy of Music building to 103 North Liberty street. Robert Stein is manager.

PHILADELPHIA — The Paxton-Crumley Automobile Company, local distributors of the Warren car and of the Warren commercial delivery car, is installed in new headquarters at 660 North Broad street, where an up-to-date agency has been established.

TOLEDO, OHIO—The pathfinder car for the Chicago Motor Club Five States Reliability Contest arrived here this week. The car is in charge of J. P. Dods and is driven by George Daubner. It is expected that the procession will pass through Toledo next month.

PITTSBURGH—The Vestal Motor Car Company has purchased a site for a service station which will cost $25,000. The company handles the trucks of the Universal Motor Truck Company of Detroit. The building will be at Grant Boulevard and Craig street.

CONNERSVILLE, IND.—A movement is on foot to provide street car service by a system of motor cars of thirty passengers capacity each. It is believed this would be as practical as an electric street car system, and that motor cars could be installed at much less expense than an electric rail line.

COLUMBUS, OHIO—The Robert F. Boda Automobile Company, of 25 North Fourth street, has closed contracts to handle the Mitchell in eighteen counties in Central Ohio for 1912. Subagencies will be selected later. The same company will cover fourteen counties in Central Ohio for the Thomas.

YORK, PA.—Norman R. Galletin, chief road tester for the past seven years, and Steward E. Myers, foreman in the finishing department of the Pullman Motor Car Company's plant, have purchased the Penn Park Garage, Park and Mason avenue, from A. B. Oden, and changed the name to the Central Garage.

BOSTON—At the meeting of the New England branch of the Electric Vehicle Association of America, at the Edison Building, Boston, an address was delivered by Stephen G. Thompson, of the Public Service Electric Company, of Newark, N. J. Mr. Thompson's subject was "The Electric Vehicle and the Central Station."

KENOSHA, WIS.—The Chicago Brass Company, of Kenosha, Wis., has purchased the buildings and real estate of the Frost Manufacturing Company, which has been specializing in plumbers' goods, and will add the property to its already large plant. The two plants adjoin and the purchase gives the Chicago company a solid block.

TOLEDO, OHIO—The Willys - Overland Company has installed a daily report system by which the office sales force is kept informed of crop, weather and commercial conditions from all parts of the United States, Canada and Mexico. George W. Bennet is in charge of the system and will use it as a barometer in his distribution of cars.

TOLEDO, OHIO—Plans are being made for the organization of a new automobile club here. The idea had its inception last week when the automobile dealers' association met for the purpose of electing officers. The club will not be a dealers' affair in any way and no one who sells automobiles will be permitted to hold office in the organization.

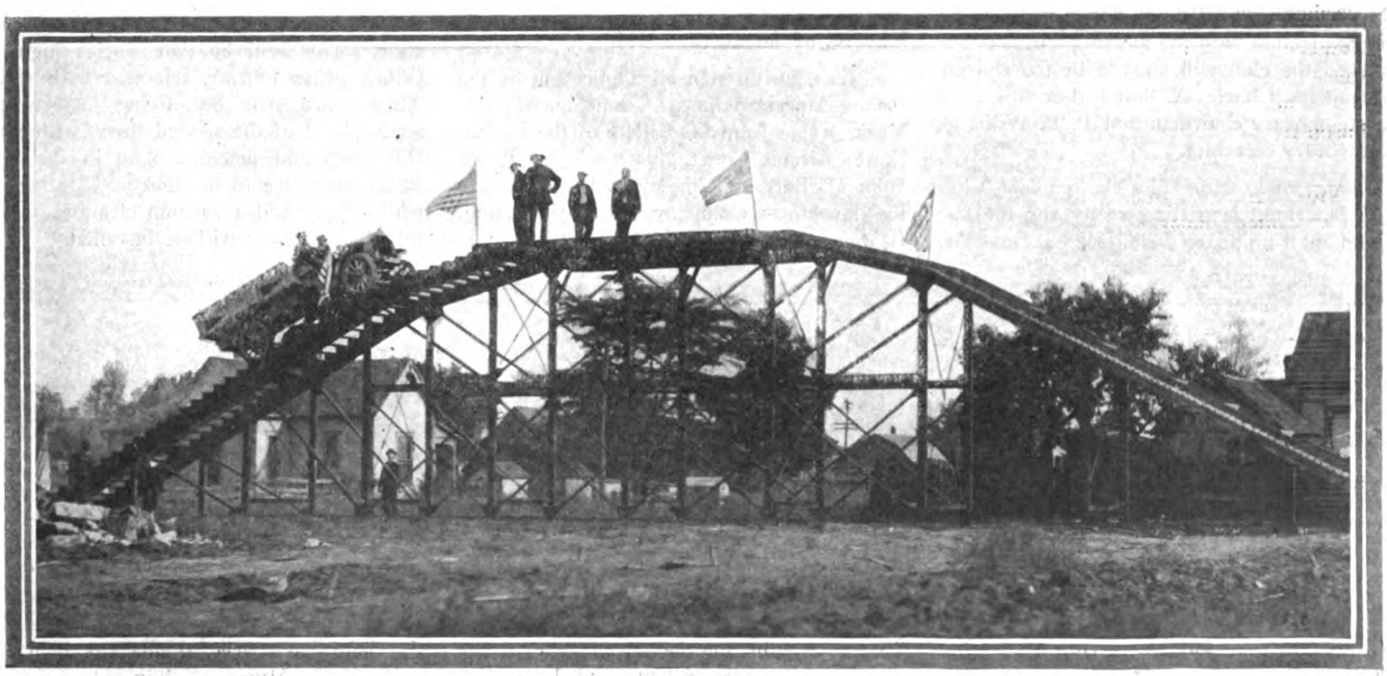
NEW YORK—The International Motor Service Association was formed last week with the avowed purpose of concentrating the purchase of supplies for taxicab, delivery and public service corporations throughout the country. Charles C. James, general manager of the taxi-cab division of the United States Motor Company, is the founder.

CORLISS, WIS.—W. Owen Thomas, designer of the Owen-Thomas Six, an all-steel car, the rights to manufacture which are owned by the leading stockholders in the Wisconsin Engine Company, of Corliss, has been granted patents on a buffer mechanism for motor cars. It is supposed that the engine company will manufacture the device on a large scale.

MILWAUKEE, WIS.—Although it has only just started to administer the new Wisconsin State aid for road building law, the Wisconsin Highway Commission has already found the $350,000 annual appropriation insufficient to meet the demands for State aid and has been obliged to scale down the requests of townships and counties to make both ends meet.

ANDERSON, IND.—The Remy Electric Company has announced that it will award cash prizes to the winners in the various events in the Fairmount Park Road Races, at Philadelphia, October 7, and in the Santa Monica races at Los Angeles, October 14. These prizes will be in gold, payable to the drivers, and are conditional upon the cars being equipped with Remy ignition.

SAN FRANCISCO—The Indian Refining Company of New York, manufacturers of Havoline oils, has organized the Indian Refining Company of California as a subsidiary corporation to handle its products on the Pacific Coast. Offices have been established in this city in charge of H. R. Gallagher and J. D. Van Eck, and arrangements are being completed to take care of the entire Pacific coast trade from a central office in this city.



Fifty per cent. gradient over which the Buckeye Manufacturing Company, of Anderson, Ind., tests its Lambert cars

DES MOINES, IOWA—The Cunningham Auto Company has taken the Des Moines agency for the American Traveler car and made a first delivery here last week.

SAN FRANCISCO—The Pioneer Commercial Auto Company of Los Angeles has established a branch in this city for the handling of the Reliance, Rapid and Randolph trucks, all of the General Motors line. F. W. Ball is in charge.

BAY CITY, MICH.—Work has been begun on Bay City's latest industry, the National Auto Truck Company's plant. The contract for the excavations has been let and the work will be completed as rapidly as possible. The contracts for the buildings will be let in parcels, none of the bids for the entire work having been satisfactory.

CHICAGO, ILL.—Instead of being held the week of September 30-October 7, the fall opening of the Chicago Automobile Trade Association will take place a week later, October 7-14, the postponement being caused by inability to complete the electric lighting of the row by that time. At present the dealers have a large fund raised for the purpose of conducting the show.

MILWAUKEE, WIS.—Albert F. Gumz, a member of the Milwaukee County Board of Supervisors, has been granted letters patent on a new type of carburetor or generator for motor cars. The device is a simplification of the ordinary carburetor and is claimed to give positive mixtures at all speeds without numerous adjustments. It is also claimed to be practically climate-proof.

INDIANAPOLIS, IND.—It is expected that a permanent organization of the Hoosier Motor Club will be perfected at a meeting of automobile owners to be held at the Claypool Hotel on the evening of September 29. There will be a dinner and smoker in connection with the meeting and it is expected the club will start with 100 charter members. Charles A. Bookwalter will serve as temporary chairman and P. P. Willis as temporary secretary.

BALTIMORE, MD.—The Automobile Club of Maryland is getting ready for the annual meeting to be held October 10. Dr. H. M. Howe, president; Thomas G. Young, treasurer; H. M. Luzius, secretary, and Osborne I. Yellott, counsel, are candidates for re-election. Vice-President Joel G. Nassauer will not run again for office. At a recent meeting the club issued warnings to motorists concerning a speed trap on Wilkins avenue, near the city limits.

FLINT, MICH.—During the Genesee County Fair, October 3, Bob Burman, in his Blitzen Benz, will have a try at the record. The other events for automobiles at the fair are as follows: Cars, Class C, non-stock, cars from 161 to 230 inches piston displacement, five miles. Prize trophy—Cars, Class C, non-stock, cars from 231 to 450 cubic inches piston displacement, three miles. Cars, Class C, free-for-all, three miles. Cars, Class C, free-for-all handicap, three miles.

BALTIMORE, MD.—The Oakland Sales Company, 107 West Mount Royal avenue, of which T. R. Jones is manager, has been appointed the agency for the new R. C. H. car. The company expects to get the first consignment of cars some time during next month. Manager Jones of the Oakland Sales Company has just returned from the Oakland factory in Pontiac, Mich., where he arranged for the shipment of the 1912 Oakland cars. The Oakland Sales Company will move to its new quarters at 6 and 8 East Chase street after November 1.

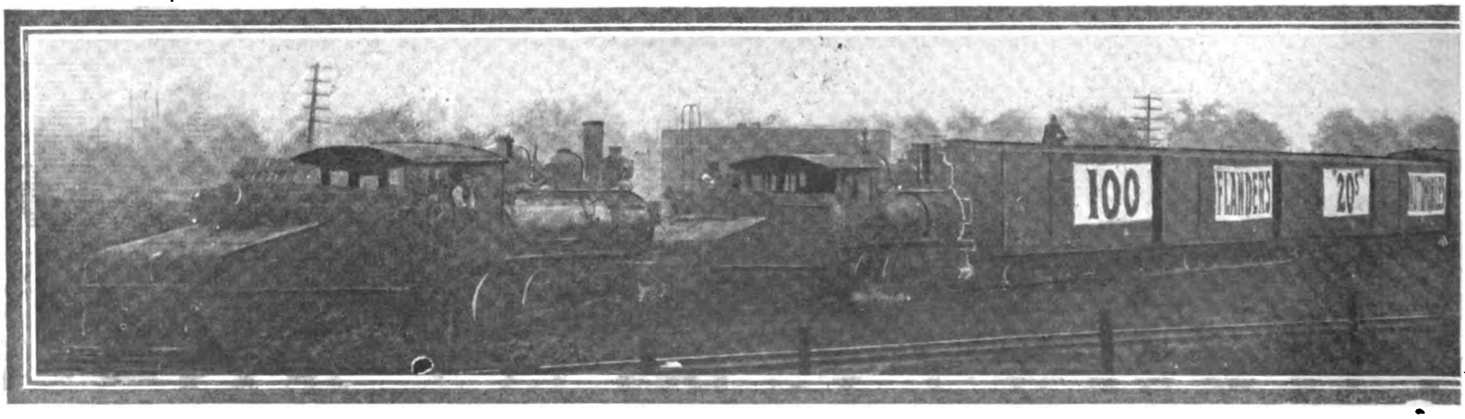
BALTIMORE, MD.—A report on the proposed plans for the Green Spring avenue boulevard within the city limits was submitted to Mayor Preston by Major Joseph W. Shirley, of the Topographical Commission. This avenue leads from the famous Druid Hill Park to the beautiful Green Spring Valley in Baltimore County, the home of many of Baltimore's smart set. In his report Major Shirley explains that it will cost $130,000 to carry out the improvements. He also suggested that the roadway be of an average width of 300 feet.

TOLEDO, OHIO.—On an application of the Ewing-American Motor Company, of New York, Judge John M. Killets of the United States Circuit Court, this week, appointed John M. Barr, of Findlay, receiver for the Findlay Motor Company, of Findlay, Ohio. It was alleged that while the company is not insolvent, it owes debts in excess of $50,000 and has not the necessary working capital to continue business and conserve the best interests of the company. Representatives of the concern consented to the appointment. Bond in the sum of $25,000 was immediately given by the receiver who is now in charge.

WASHINGTON, D. C.—Under bids opened some weeks ago the Bureau of Yards and Docks, Navy Department, has awarded the General Vehicle Company, of Long Island City, the contract for furnishing twelve electric trucks to navy yards at Portsmouth, N. H.; Boston, New York, Norfolk, Charleston, S. C.; Mare Island, Cal.; Puget Sound, Wash., and Guam. The contract price was $49,000. Eight of the trucks will be 5,000-pound machines in four of them 10,000-pound trucks. The 5,000-pound trucks will be of the express type, while the others will be of the stake type. Delivery is to be made within six months.

INDIANAPOLIS, IND.—K. W. Brewer and E. L. Baker have formed the Baker-Brewer Company and have taken the agency for the Baker electric. They have obtained quarters with the downtown salesroom of. the National Motor Vehicle Company at 426-428 North Capitol avenue. The Haynes Automobile Company, of Kokomo, has opened a factory sales branch in Indianapolis at 514 North Capitol avenue, with R. P. Dillon as manager. A factory sales branch of the Auburn Automobile Company has been established at 518 North Capitol avenue. Formerly the Auburn was handled by the Finch-Freeman Auto Company.

INDIANAPOLIS, IND.—There is a constantly increasing demand for garages in the residence districts and there is a tendency to erect such garages to conform to the architectural surroundings. The Automobile Owners' Service Company has just begun the erection of a building on the colonial style. This will be two stories high, of yellow pressed brick, trimmed with white. There are to be living apartments at the front of the second story, with a repair shop and machine shop in the rear. Motor cars are to be delivered by men in white livery and a vacuum cleaning system for cleaning cars will be installed.



Among the notable features of the early autumn shipping season is the solid trainload of Flanders cars which left the factory

CINCINNATI, O.—It has been decided by the Cincinnati Automobile Dealers' Association to hold its second annual show in Music Hall during the month of February next. Contract has been listed for the hall, the exact date to be announced soon.

MILWAUKEE, WIS.—Good roads was one of the principal subjects for discussion at the annual convention of the National Rural Letter Carriers' Association in Milwaukee, September 20 to 23. Traveling an average of 26 miles per day on the roads of the United States, the rural carriers are to be considered among the best judges of roads. Several motor car manufacturers made exhibits at the convention, among them Mitchell-Lewis Motor Company, Racine, Wis.; Petrel Motor Car Company, Milwaukee; Schacht Motor Car Company, International Harvester Company and Maxwell-Briscoe Mfg. Company.

SAN FRANCISCO, CAL.—Announcement is made by the Motor Car Dealers' Association of San Francisco that no gasoline pleasure vehicle show will be held in this city by them or under their sanction. This means that there will be no show this season, for, after the unpleasant experience of private promoters who attempted to hold an exhibition last March against the wishes of the association, it is not probable that any such will be attempted again. At that time the organized dealers published several announcements that they were not participating, and this, combined with bad weather, resulted in serious financial losses to the promoters.

MILWAUKEE, WIS.—As a result of the convincing demonstrations and tests made by manufacturers of motor-propelled fire-fighting equipment during the twenty-third annual convention of the International Association of Fire Engineers in Milwaukee, September 19 to 23, the Common Council of Milwaukee will proceed at once to motorize the entire equipment of Central Fire Station, Broadway and Oneida street.

MONTREAL.—The $6,400 motor - driven combination hose wagon and chemical engine, which was authorized by the Westmount Council Tuesday night, will be the first piece of fire-fighting apparatus of its kind to be adopted in Montreal and in fact in the province of Quebec. Westmount's experiment will be watched with interest by the Montreal Fire Department, which has for some time past been contemplating the purchase of a similar piece of apparatus.

GRAND RAPIDS, WIS.—The Commercial Club of Grand Rapids has obtained sufficient subscriptions to meet the guarantee demanded by W. A. Crowe, of Detroit, who proposes to manufacture a new 30 horsepower car to be known as the Crowe. It is now considered certain that the new Crowe plant will be established in Grand Rapids. It is proposed to incorporate for $200,000, of which amount $40,000 is to be awarded to Mr. Crowe and W. M. McIntyre, designer of the car, as their share for patent rights, designs, tools, etc.

SAN FRANCISCO—The White gasoline pleasure cars are now handled in San Francisco by the Davis Auto Company, organized for the purpose. The White company's branch here retains the truck end of the market. Frank H. Davis, long associated with the White branch, is manager of the Davis Auto Company.

RICHMOND, VA.—With the proviso that the money be expended within ten miles of the city, the finance committee of the City Council has recommended the appropriation of $5,000 by the Council toward the Gordonsville-Richmond-Old Point highway improvement. Private subscriptions amounting to over $6,000 have been made toward the improvement of the highway, and more donations are being solicited. The counties and towns along the highway are coming across liberally and every indication is that a sum sufficient to put the highway in the very best of condition will be raised.

CHARLOTTE, MICH.—The Duplex Power Car Company's affairs took a new turn when the adjourned annual meeting of the company was held and an entirely new set of officers and directors was chosen to take charge of affairs, comprising Frank P. Town, James H. Brown, Robert Donovan, W. G. Wisner, Frank King, W. B. Fulton and M. J. Lamson, all local men. Later the board met and elected the following officers: President, Frank P. Town; vice-president, Frank King; secretary, W. G. Wisner; treasurer, Carroll S. Brown.

Automobile Incorporations

AUTOMOBILES AND PARTS

BOSTON, MASS.—Hollander Motor Co.; capital, $15,000; to sell motor vehicles. Incorporators: Wilkie B. Hollander, George M. Wetherbee, Robert A. Jordan.

DAVENPORT, IA.—Davenport Auto Co.; to deal in motor cars. Incorporators: A. A. Liberman, Charles E. Frey.

FAIRBURN, GA.—Piedmont Auto Manufacturing Co.; capital, $100,000; to build automobiles. Incorporators: Robert F. Butler, W. L. Moor, H. Knight.

MARIETTA, OHIO.—Pioneer Motor Car Co.; capital, $18,000; to make and deal in automobiles. Incorporators: Tasker B. Bosworth, A. J. Watson, A. A. Crawford, T. McCune, H. B. Coen.

NASHVILLE, TENN.—Hicks Motor Truck Co.; to make freight automobiles. Incorporators: W. L. Hicks and others.

NEWARK, N. J.—Merchants Motor Car Co.; capital, $500,000; to manufacture automobiles.

PROVIDENCE, R. I.—Providence Motor Car Co.; capital, $25,000; to sell automobiles and conduct garage business. Incorporators: John A. McDonald, William H. McSoley, Alice Stanton.

RICHMOND, VA.—Motor Truck Corporation; capital, $25,000; to operate a motor transfer business. Incorporators: H. A. Gillis, T. M. Garrity, Charles Laurens, E. P. Cox.

UTICA, N. Y.—Tompkins-Creedon Co.; capital, $5,000; to deal in automobiles. Incorporators: Wm. Tompkins, Dennis P. Creedon, Ella Creedon.

TERRE HAUTE, IND.—Smith Motor Car Co.; has changed name to Terre Haute Motor Co.

WILMINGTON, DEL.—Union Motor Car Co.; capital, $25,000. Incorporators: Edmund S. Hellings, Charles B. Bush, Armon D. Chaytor.

AUTOMOBILE GARAGES, ACCESSORIES, ETC.

BUENA VISTA, VA.—Buena Vista Garage & Automobile Co., Inc.; capital, $5,000. Incorporators: W. B. Pritchard, S. H. Yoekely, D. S. Bromley, N. B. Pritchard.

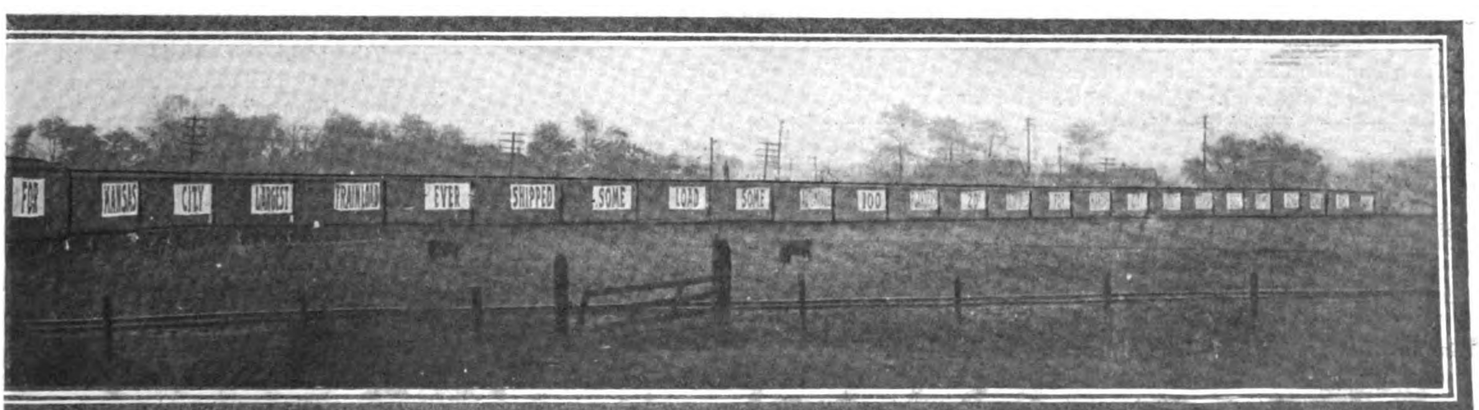
CLEVELAND, OHIO.—Sea Island Tire Co.; capital, $15,000; to make and sell tires and tire protectors. Incorporators: J. C. Brooks, A. L. Welch, A. C. Miller, D. C. Westenhaven, W. H. Boyd.

NEW YORK CITY.—Green's Auto Vans Express Co.; capital, $12,000. Incorporators: James C. Green, Michael Green, Daniel S. Green, Joseph Green.

NEW YORK CITY.—Smith Gasoline Meter Co.; capital, $350,000; to make and deal in engines, motor cars, etc. Incorporators: W. H. White, Jr., D. M. Baldwin, W. H. Brady.

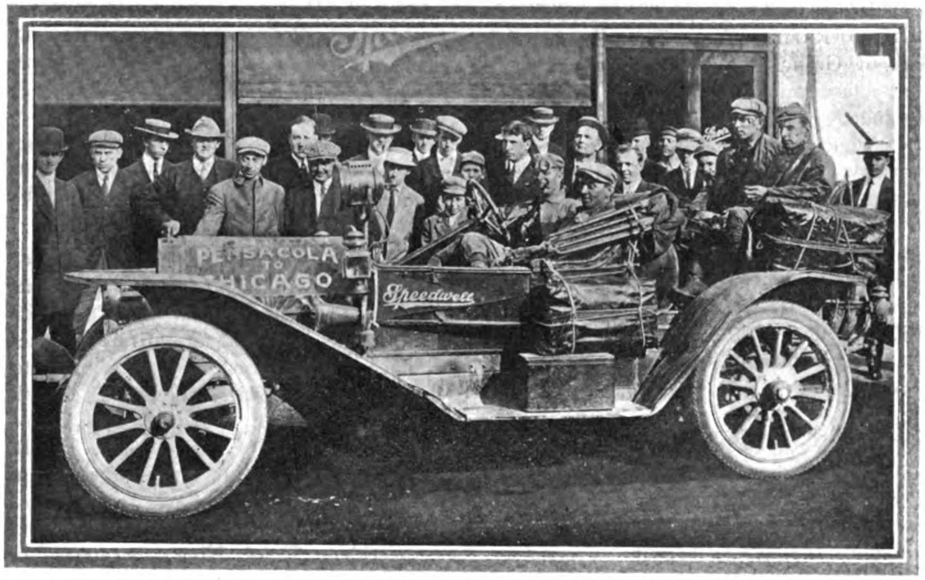
CAMDEN, N. J.—New Jersey Automobile & Supply Co.; capital, $125,000; to sell automobiles. Incorporators: H. Morgan Hatch, J. R. Mick, Wilfred B. Walcott.

JERSEY CITY, N. J.—Moran's Garage & Auto Co · capital, $25,000; to sell automobiles. Incorporators: Ottilie R. Moran, John E. Moody, Wm. A. Higgins.



at Detroit for the Kansas City branch recently. The train was made up of 34 cars, and 100 automobiles constituted the shipment

OF INTEREST to the INDUSTRY



CHICAGO, ILL.—There recently arrived here from Pensacola, Fla., the Speedwell Pathfinder, which left the Southern city nine days before to lay out a Gulf-to-Lakes route designed to facilitate and encourage motor travel between the South and North. The trip was made under the auspices of the Pensacola Commercial Association, with Dr. Mallory Kennedy in direct charge of the work. Although no effort was made to cover the distance speedily, the time consumed on the long journey is considered remarkably fast. The information gathered en route by Dr. Kennedy is to be put into convenient shape by the Association.

SYRACUSE, N. Y.—R. A. Vail, assistant chief engineer in the Franklin factory, has resigned. A delivery wagon of 1,000-pound capacity is a feature of the commercial car line of the Franklin Automobile Company as it is presented for the coming season.

RACINE, WIS.—The J. I. Case Threshing Machine Company is now giving its new petroleum engine a thorough tryout in connection with a threshing machine. The motor car department of the Case company is taking considerable interest in the new type and experiments are being made in this department. The engine is designed by David Evans.

SYRACUSE, N. Y.—John A. Nichols, Jr., former district manager for the Franklin Automobile Company in the Canadian and American Northwest, has been made superintendent of the Franklin branches with headquarters here.

GRAND RAPIDS, MICH.—The Mercury Manufacturing Company, a Chicago firm which manufactures the Mercury half-ton trucks, has chosen Grand Rapids as the place to enter into Michigan competition. Its first branch in this State has been established at 318 Kent street. The company is represented by James Hoogerhyde and C. Fisher.

CHICOPEE FALLS, MASS.—H. B. Curtiss was recently placed in charge of the Service Department of the Stevens-Duryea Company at its factory. Mr. Curtiss was formerly connected with the Pierce-Arrow factory organization.

DETROIT, MICH.—By the middle of November the Abbott Motor Company expects to get into its new addition. This building is 40 by 160 feet and will be used for final assembly and general storage purposes. The new office building will be ready by Oct. 20.

LIMA, OHIO—Steps have been taken by the Gramm Motor Car Company of Lima, Ohio, to increase the capital stock of the corporation from $300,000 to $1,250,000, for the purpose of increasing the output of the plant. Of the increased stock half will be common and the other preferred.

DES MOINES, IOWA—W. R. Jones has been named manager and has taken charge of the Des Moines branch of the United States Motors Company. Mr. Jones was formerly in charge of the Kansas City branch. He succeeds H. B. Groves, who has gone to the Pacific Coast.

AMESBURY, MASS.—The new plant of the Castle Lamp Company at Elmira, N. Y. is approaching completion and will be ready for occupancy October 15. The building is 227 by 85 feet, three stories high and constructed of steel and cement. The Amesbury plant will be removed to Elmira.

SAGINAW, MICH.—John Trumble, of Detroit, has been appointed superintendent of the engineering department of the Marquette Motor Company and has assumed his new duties. The Saginaw plant is being used strictly as a manufacturing adjunct to the General Motors Company, and besides building its own cars is making all parts of Welch-Pontiac and Welch-Detroit cars and furnishing them to owners of these automobiles.

LANSING, MICH.—The fiscal year of the General Motors Company has been changed so as to end July 31 in place of September 30, as heretofore, in order to permit the manufacturing department to take inventory at the most convenient time of the year. This will mean that the forthcoming statement of earnings will be for a ten-months' period, running from October 1, 1910, to July 31, 1911.

LOUISVILLE, KY.—Berton B. Bales has resigned as president of the American Automobile Manufacturing Company, whose offices and plant are situated across the river from this city in New Albany, Ind. It is understood that George H. Wilson, of Louisville, will be selected as Mr. Bales's successor. The later will retain his interest in the company, but will devote his time to his private business affairs. The company makes the Jonz car and at present about sixty workmen are employed.

BROCKVILLE, CANADA—The Brockville Atlas Motor Car Company, with a capital of $200,000, has been established at Brockville, Ont. A new factory with all the latest facilities is in course of construction. This company will build four different types of cars—touring car, runabout (two models) and commercial car. All the parts will be built by the company with the exception of the engine and body. The engine will be the output of The Atlas Engine Works of Indianapolis and the bodies constructed by the Canada Carriage Company. Mr. T. J. Storey is the managing director.

AKRON, OHIO—The annual meeting of the stockholders of the Swinehart Tire & Rubber Company was held at the offices of the company recently. Very satisfactory reports were made of the progress of the company during the past year, the business showing an increase over the previous year of 200 per cent. The prospects for the coming year are very good, the factory operating day and night to take care of the increased business. The following were elected as directors for the ensuing year: August Blossman, R. A. May, L. Mather, Wm. McWeldon, W. W. Wuchter. After the stockholders' meeting the board was organized and the following officers elected: W. W. Wuchter, president and general manager; Joseph Dangel, vice-president; C. O. Baughman, secretary; R. A. May, treasurer.

PATENTS GONE TO ISSUE

ROLLER BEARING — Anti-friction bearing containing two sizes of rollers.

2. The bearing shown in Fig. 1 comprises spaced concentric race rings I and O, the inner ring I having a peripheral groove G with outwardly inclined edge portions at its sides. Ring I also has annular wearing surfaces W on opposite sides of the edge portions mentioned, and at the outer edges of these annular surfaces radially disposed flanges are spaced. Working rollers R_1, the ends of which have beveled edges, are located in the peripheral grooves G, and these rollers are held apart by separator rolls R_2, which bear against the surfaces W and are interposed between the flanges and a retainer R_3 which has spaced openings through which the working rollers R_1 pass into coaction with the outer race O.

No. 1,003,551—to Colcord Upton, Baltimore, Md., assignor to Simplex Roller Bearing Co., New York City. Granted, September 19, 1911; filed June 8, 1911.

COMBINED MUFFLER AND AIR HEATER—Air playing around the silencer is heated by the exhaust gases passing through same.

2. This patent relates to the device shown in Fig. 3, in which C denotes an outer muffler casing having an exhaust inlet I at one end and an exhaust outlet O at the other. Intercommunicating sections are arranged transversely of and closely fitting the interior of the casing, each section being formed by two oppositely disposed, centrally perforated members M and N having flanged edges and a baffle plate B located between them. Plate B is perforated at P and P_1, beyond its center, and at its margin it is connected to the flanges of the two concave members mentioned. Thus the outer margins of the hollow sections have openings out of alignment with each other, which provide a tortuous gas passage. While the exhaust passes through the plurality of sections, air, which is permitted to enter at A, flows around these sections as indicated by the arrows, until it reaches the discharge opening D whence it streams through a pipe to the ventilator cap V arranged in the wall of the automobile body B.

No. 1,003,620—to Edward Dudley Lewis, Elmira, N. Y. Granted September 19, 1911; filed April 18, 1910.

ADJUSTABLE BRAKE—By means of a bolt tension on brake-band may be altered.

1. In Fig. 4 is shown the combination with a drum D and a fixed support S of a brake band B, B_1 encircling the drum and carrying a stud S_1 at one of its ends. In this stud a bolt B_2 is adjustably mounted, which is connected to the link L, one end of which is pivotally mounted on the support S and the other connected to the free end of the bolt. An operating lever O has one end pivotally connected to the brake band at P, while the other end E, when in use, is connected to an operating rod, the intermediate portion of the operating lever being connected to ends of link L and bolt B_2.

No. 1,003,621—to Charles L. Lincoln, assignor of one-half to Samuel H. Wheeler, Bridgeport, Conn. Granted September 19, 1911; filed December 28, 1910.

ODOMETER—Distance meter of the kind connected directly to the wheel hub.

1. This device comprises an annular housing adapted to embrace the wheel hub, a registering device within the same and an actuating device for the register consisting of a circularly curved lever having a fulcrum within the annular housing and on one side of the center of same, a weight being attached on the opposite side of the annular housing with respect to the center of the wheel hub, and means for connecting the circularly curved lever to the register.

No. 1,003,623—to Kendree Littleton, Pacolet, S. C. Granted September 19, 1911; filed May 23, 1911.

PNEUMATIC VEHICLE CUSHION—Shock absorber taking thrust by inflated tubes.

3. The invention protected by this patent is seen in Fig. 2. Above the spring S the axle A is mounted, which carries the cushioning device consisting a frustrum-shaped member F mounted directly on the axle and extending above it as shown; F has an horizontally extended base B, between which and an upper inverted-dish shaped member U pneumatic tubes P and P_1 are interposed. Rods R are fastened to the spring and pass through the frustrum-shaped member, and they are bolted to the member U at B and B_1, permitting U to vibrate vertically with the spring.

No. 1,003,579—to George J. Bancroft, Denver, Colo. Granted September 19, 1911; filed June 7, 1910.

ENGINE SILENCER—A muffler construction in which the gases pass through a spiral passageway.

1. This muffler consists of a casing containing semi-circular sections arranged to form a continuous spiral passage through the casing, the sections adjacent the inlet having central apertures while the other sections have closed conical centers with their apices toward the muffler inlet.

No. 1,003,531—to Lonnie C. Smoot and Wm. R. Masterson, Hillsboro, Tex. Granted September 19, 1911; filed Sept. 6, 1910.

TIRE PROTECTOR—A system of cables and rings is employed to keep the pneumatic tire in place on the wheel rim.

This patent relates to a tire protecting device, which consists of two rings encircling the wheel rim adjacent to its two sides. Around the rings and over the tire tread is led an endless cable, and to prevent slippage of the cable clamping rings co-operating with the first-mentioned rings are used, which are secured in their places.

No. 1,003,815—to Charles Scott, Baker, Ore. Granted September 19, 1911; filed May 10, 1911.

Newest Ideas Among the Accessories

Star Safety Starter

THE Star Starter, which is shown in Fig. 1, serves to start a motor car from the driver's seat by means of a lever, and it contains in its construction

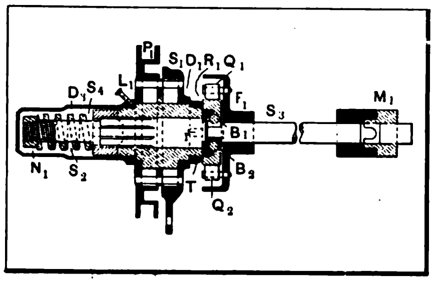

Fig. 1—Section through Star starter

a safety feature protecting the operator from the effects of backfiring. The front view of a car equipped with the Star starter is seen in Fig. 2, where P1 represents a pulley around which is wound the starting chain C1, which is led around pulley P2 to the operating cable actuated by the lever beside the driver. C2 is the castellated front end of the starter housing, and around it is fitted the dog D3 holding it to the frame by means of two bolts. In Fig. 1 the mechanical details of the starter are depicted, P1 denoting again the main pulley, which is fastened by pins to the frame S1 of the starter. These members are arranged around the starter shaft S4, carrying also a ratchet R1 and dog D1. Shaft S3 runs on a ball bearing B1, B2. To the dog F1 two pawls Q1 and Q2 are connected by means of bolts, these pawls engaging the ratchet and insuring its rotation in one direction only.

Referring to the front end of the starter, it consists of the spring S2 which is wound around S4 and serves to counteract the initial compression of the motor, while nuts N1 are used to adjust the tension of the spring. The whole of this part of the

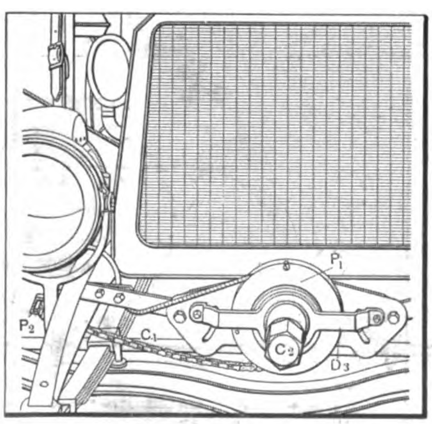

Fig. 2—View of Star safety starter

starter is covered by the dust-cover D2, fastened to pulley P1 by lock stud L1.

In starting, the chain being pulled toward the driver turns over pulley P1, which it engages, and also starter frame S1 pinned thereto. The engagement of pawls and ratchet causes shaft S3 to be turned over, and a minimum amount of work is expended in starting as the compression of the motor is balanced by the spring S2 and as the ratchet is carried on a ball bearing. Shaft S3 twists the crankshaft M1 of the motor around, thus starting the engine. Should the motor back-kick, the pawls will keep the ratchet from reversing its motion. Likewise, after the motor has

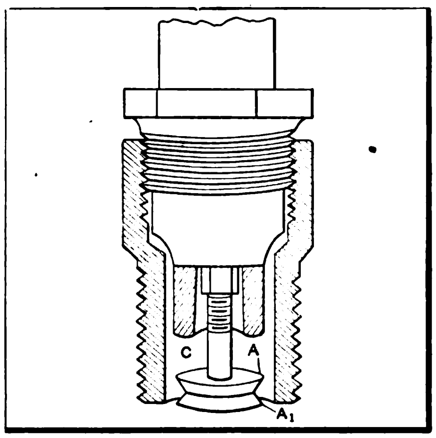

Fig. 3—Section of Maher Duplex plug

been started, the pawls are thrown out of engagement with the ratchet (and starter) by centrifugal force. The Star Starter Company of Rochester, N. Y.

Duplex Spark Plug

The Maher Duplex Multi-Spark Plug, claimed by its makers to be self-cleaning, has a double annular spark gap (Fig. 3), formed by two cone frustrums fixed at their smallest portions and centrally disposed in the bottom end of the spark plug body. The flange A of the upper frustrum serves as a normal sparking "point," while the lower flange B provides an auxiliary gap. The lower flange also acts as a baffle plate closing the firing chamber C against oil from the cylinder space. In the firing chamber gasoline-air mixture is stored and compressed during the compression stroke, and when ignited it expands most rapidly, shooting out of the firing chamber and tearing soot and foreign matter off the spark-gap flanges. The Duplex Multi-Spark Plug Company, of Devil's Lake, N. D., makes this plug.

Perfect Window Regulator

The device shown in Fig. 5 is the product of the Perfect Window Regulator Company, of 43 Exchange Place, New York City, and is intended to do away

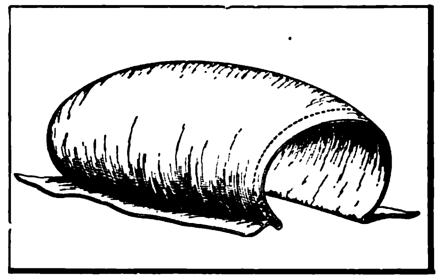

Fig. 4—Security blowout tire patch

with the troublesome strap generally used for opening the window of a closed car. Fig. 5 shows the window which is fastened to cam plate C1, which is held by the spindle S to the chain C2. This chain is led over the two sprockets V and W, and the latter may be rotated by means of the handle H, thereby lifting or lowering the window. The handle contains a clutch member holding it locked in any position, but permitting it to be released by turning.

Security Blowout Patch

The Security blowout patch (Fig. 4) is intended to be used between the inner tube and the tire casing to prevent blowouts or to serve as a repair in case of blowouts. It is composed of a series of tire-fabric layers, moulded on an aluminum form, giving it the exact dimension of the inside of the casing. The outside of the patch is coated with a quick vulcanizing compound. It is made by the Security Reliner Company, Montgomery, N. Y.

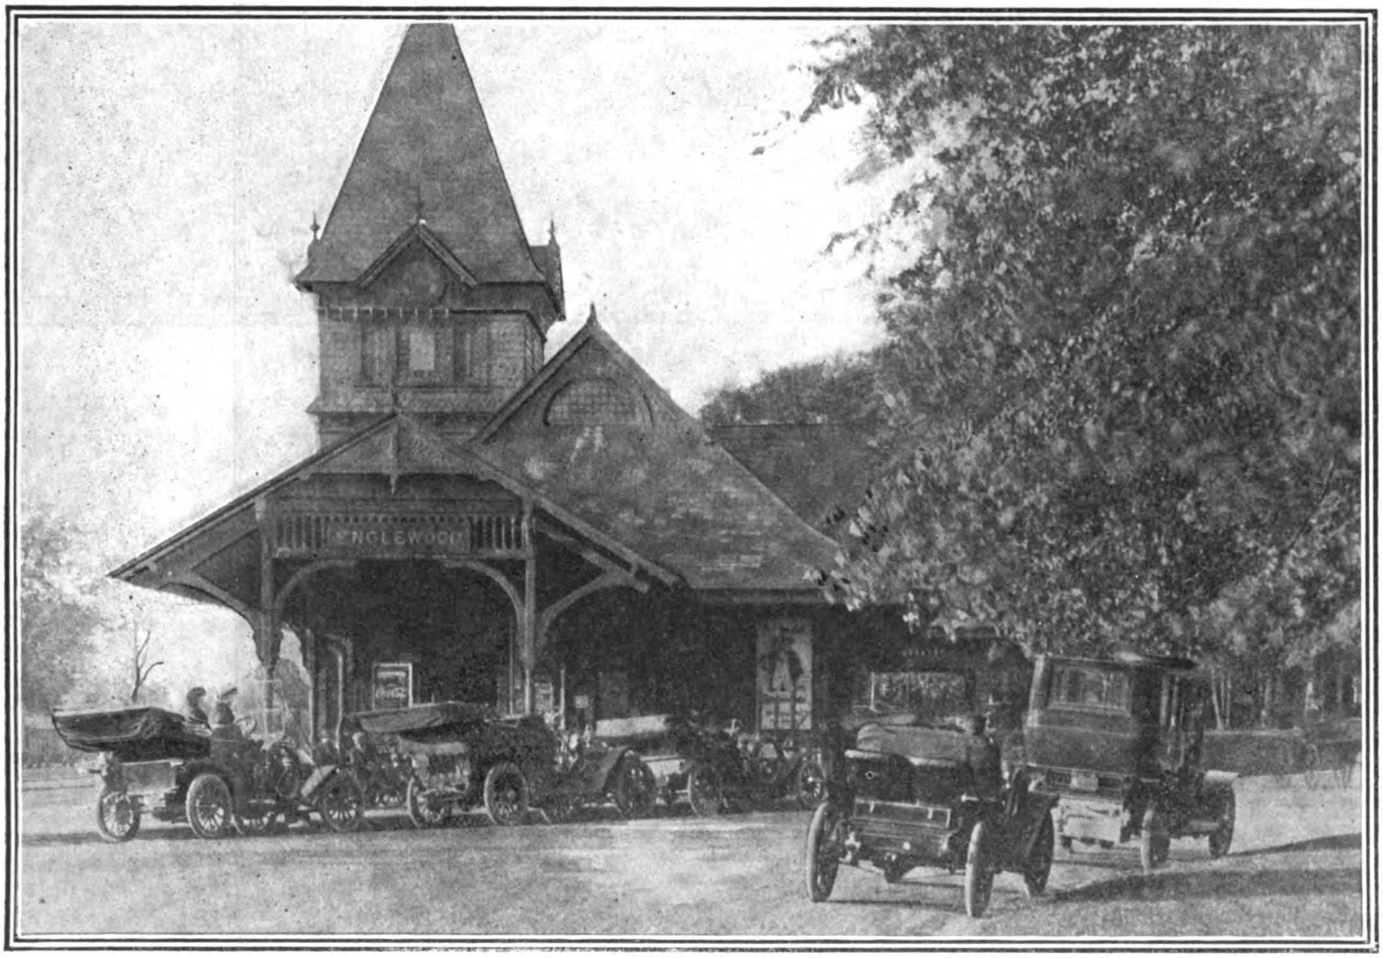
VOL. XXV. NEW YORK—THURSDAY, OCTOBER 5, 1911—CHICAGO No. 14

THE AUTOMOBILE

Commuting via the Automobile



HOSTS OF CARS CARRY SUBURBAN OWNERS TO AND FROM RAILROAD STATIONS EVERY BUSINESS DAY IN THE YEAR

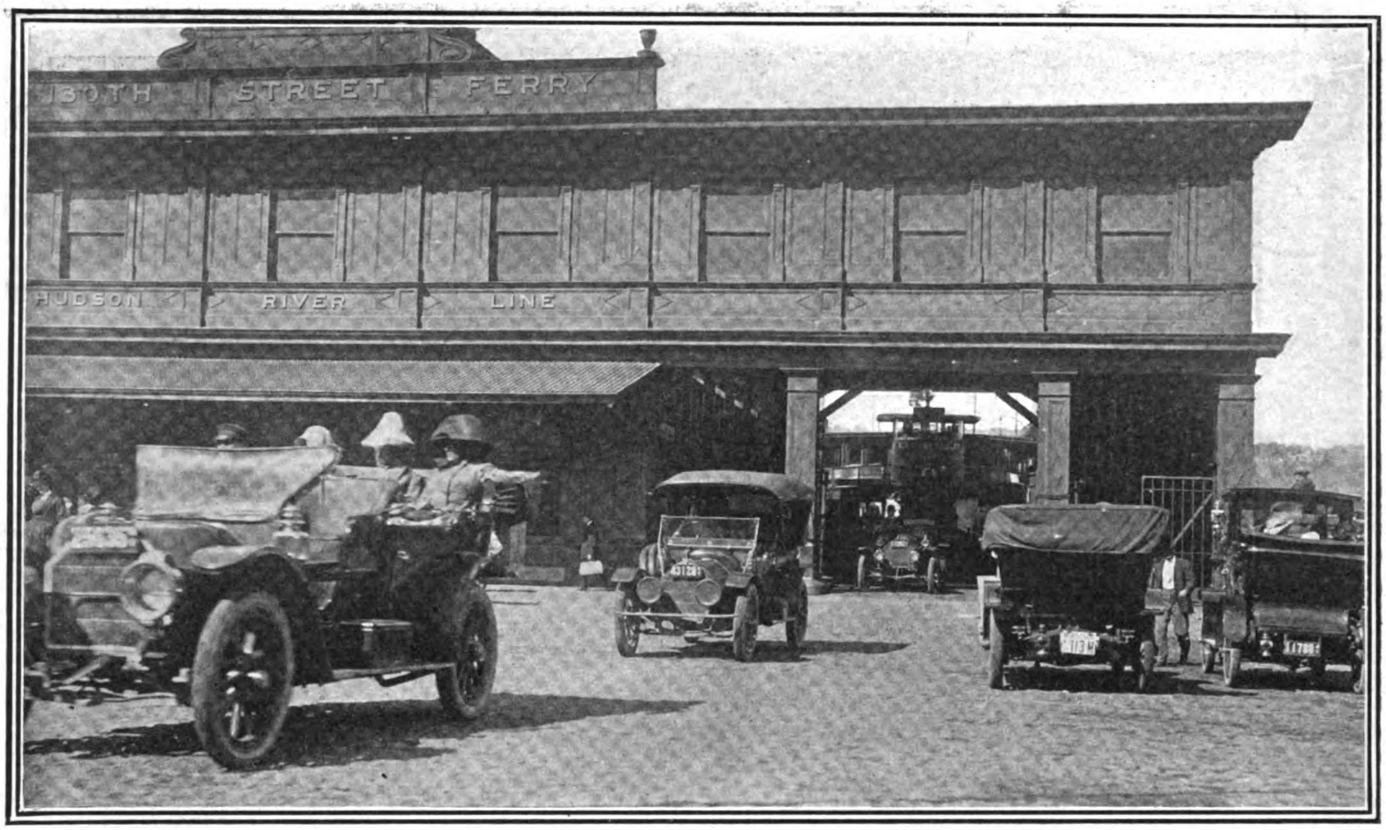
HOW many are aware that residential building on Manhattan Island is steadily decreasing, despite the vast improvements that are being placed in Harlem, Washington Heights and throughout the north end? Yet it is true. The millionaires have stopped erecting palaces in central New York City, and the reason for this condition rests upon the automobile.

There is still plenty of space for such castles as those of Carnegie, Rockefeller, Clark, Vanderbilt and Astor, but the fact remains that new buildings of their class are not being erected and are not in prospect as far as Manhattan Island is concerned.

Likewise, and even more important, as showing the trend of affairs, is the condition to be noted with regard to homes for business men in comfortable circumstances, who do not come within the multi-millionaire class. They, too, are avoiding the building of homes on Manhattan Island, precisely the same reason applying as does to the situation of the very wealthy.

The figures for the first six months of 1911, covering building permits issued for construction and alteration on Manhattan Island, reach a total of $62,662,717. As about 70 per cent. of all building permits in any one year are issued during the first six months of the calendar period, the expectation of Manhattan for the whole of 1911 is for buildings to cost $89,518,160.

In 1910 the total of all building permits was $108,643,090, thus indicating a decrease this year of $19,124,930 as compared with the estimated figures for the year. From 1909 this slumping tendency was even more noticeable, as the total amount of the



The automobile plays an important part in keeping the suburbs in touch with the metropolis

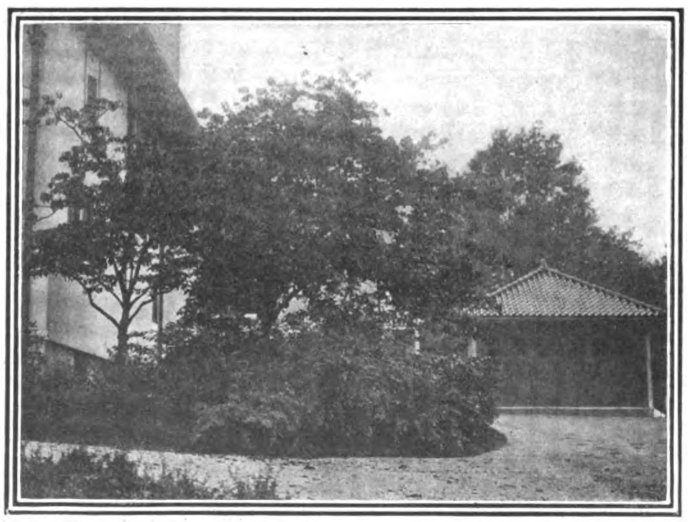
permits was $144,103,507, and 1910 showed a decrease of $35,-460,417 in comparison.

One will look in vain to business conditions for a reason upon which such a decrease in city building can be predicated.

On the other hand, the places near New York that were considered wildernesses only a few years ago are now crowned with splendid homes. From the city limits on all sides the city is growing. Even as far as 40 miles from Wall street, the captains of industry, as well as the lieutenants, sergeants, corporals and privates, have been busy in building their homes.

Take an automobile and go out from New York in any direction, either up-state, across in Jersey, out into Connecticut, upon Long Island or down on Staten Island, and the striking feature of the trip will be the vast number of fine new residences that have gone up recently or are in process of construction.

To the automobile solely is due the credit for this expansion, for, in the broadest sense, the scattering out from the centers of congestion is wholly advantageous. No man would contend that it is not more pleasant to live and sleep in a comfortable modern house, surrounded by the beauties of nature and far from the noisy pavements and the crush and jam of the great city, than it would be to live in the same kind of a house in the midst of the urban maelstrom. On the other hand, the spaces vacated by those who are able to make the transfer of their homes from the city to the country, allow room for others to move in, and by gradual transition the teeming East Side is relieved.



Cement and tile are frequently seen in the structural work of modern country homes

Out on the rocky Connecticut hillsides, miles away from any railroad, the building is going on industriously. Away north of Mount Vernon, White Plains and Larchmont, in Westchester County, palatial homes are being added each season by the dozen; far to the east of the lateral median line across Long Island, the seekers for the surroundings of nature for their homes are spreading out; while in Jersey the same trend is pronounced.

The Connecticut farmer to whom had descended a big, barren stretch of land close to the Westchester County line and who was about to abandon it five years ago because he could not wring a living from its dry soil and hard rocks, and who despaired of getting $10 an acre for his homestead, faces a very different situation to-day. Then he could find no one to lend money on such land and no one would agree to pay the taxes and work it on shares, or any other way.

With the coming of the automobile, which brought good roads in out-of-the-way places and a stream of wealthy tourists who could appreciate the natural beauty of the landscape without being impressed with the barrenness of the country, the price and value of his land increased wonderfully. The farmer who held his 160 acres through those dark years is beyond want to-day, for in many sections of Connecticut, near New York, values have risen from $5 an acre to $500, and in particular cases to as much as $3,000 an acre.

This same land to-day is worthless for agriculture and could not be made to pay as a farming project except through the use of scientific fertilization and the modern school of production. But it forms the groundwork for dozens of fine country homes where New York business men rest and recuperate from the fierce strain of their work.

This is the way they do it: Suppose that a wealthy New York family in touring about the Connecticut hills, or Westchester wilderness, or Long Island woods, or Jersey mountains, finds a wild crag or wooded hillside or smiling valley and thereupon decides to push back the limits of space and get away from the nuisance of the crowds, the bustle, noise and discomfort of the city to enjoy the calm peacefulness, the good air, the beauty and the elbow-room of the country.

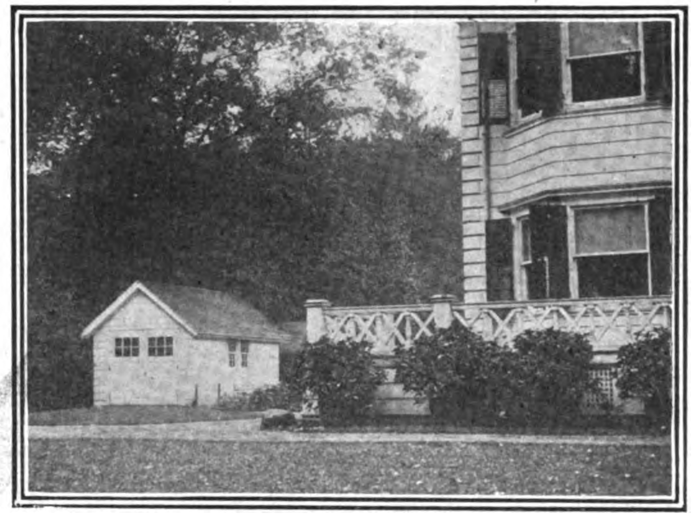
Crags, woodlands, valleys and hillsides have had a persistent bull market for the past two years or more, and it is likely that the family will have to pay roundly for the home site, but when the idea is once firmly implanted it is the hardest of all human ideas to displace and as a general rule the trade is closed.

Then the home is built and the family moves in. If the place is several miles from the railroad, so much the better. In the morning the head of the house and male members who have business in the city, step into the touring car, and, after a bracing ride, reach the station, and from anywhere within a radius of 40 miles can be anywhere in New York within the hour. The feminine members of the household can run all the way into town in the limousine or touring car for shopping or social duties and be at home by dinner time.

Then to go back again to the men: When the 5:17 train pulls into the home station, father and the boys and the visitors for a week-end, for instance, alight and the seven-passenger touring car whisks them out into nature's domain and lands them at home with sharpened appetites and alert minds and bodies.

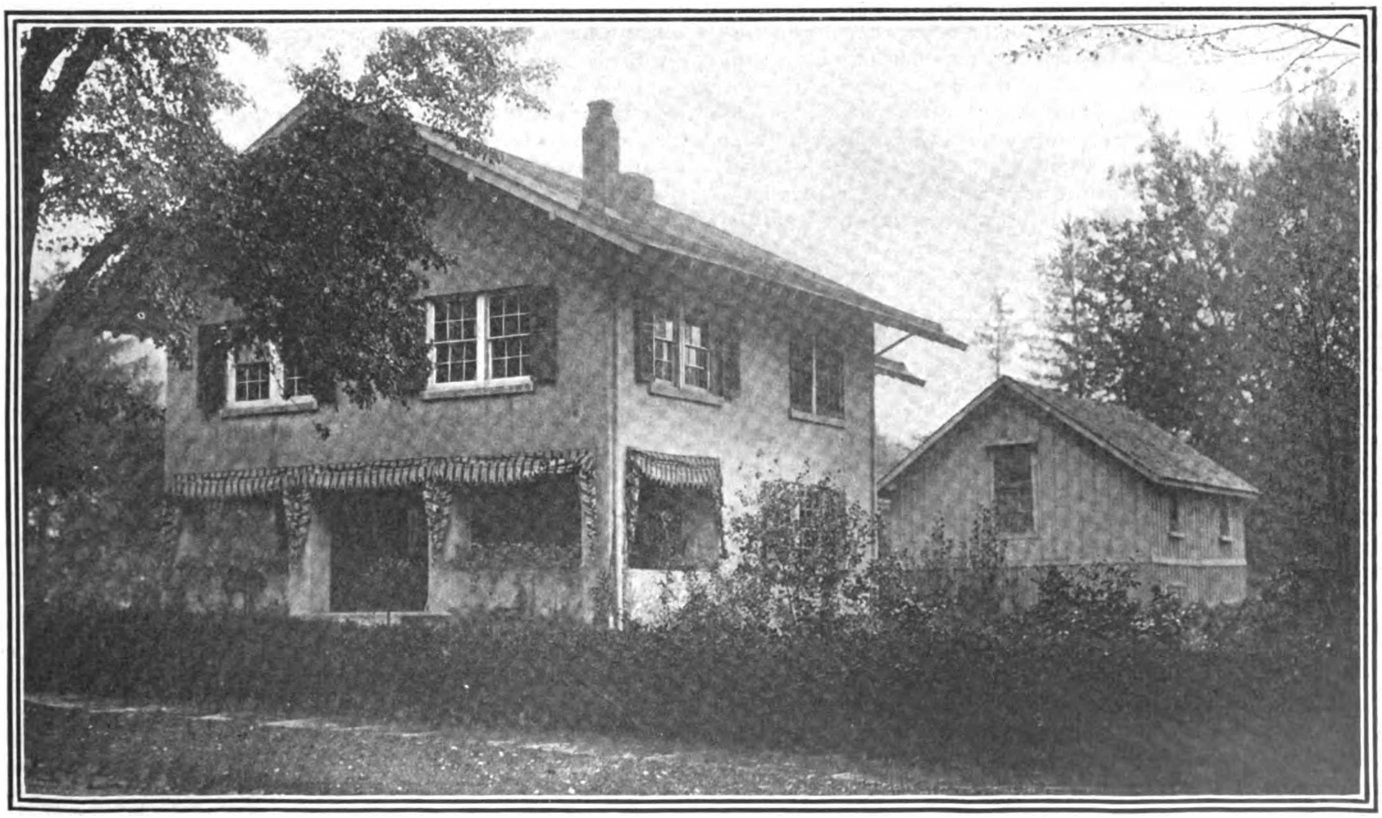
The above illustration might be said to describe the method of life of 100 very rich men who still own vast homes on Fifth avenue and Broadway, but who spend nine months in each year at their country places, besides appearing at their offices every working day in the year except while on vacation.

For every one of the above there are 100 men in moderate circumstances who have abandoned New York City as a place of residence while still maintaining their business connection with the big town. Many of these live in isolated spots like their very rich brethren, but the bulk of them form the backbones of communities surrounding New York like the circumference of a circle. In the Oranges of New Jersey, it would be difficult to throw a half-brick without hitting a Standard Oil officer; in Englewood, about 20 per cent. of the wealthy class make the pilgrimage to Wall street daily; Mount Vernon, Yonkers, White Plains, Pelham, Larchmont and the outlying districts between them contribute a vast army of solid citizens every day, while the hill country of Connecticut, west of Stamford, is honeycombed with the homes of New Yorkers. The same may be said for Long Island and Staten Island, and every last one of the families represented by this newest and most effective back-to-the-soil movement owns at least one automobile.



A typical country residence and small garage located where participation in New York life would be impossible without the automobile

But there is still another class involved in this development—the high-salaried employees of the New York business houses and the prosperous business and professional element. These are moving out of the congested center toward the comfortable circumference of the circle. They are striking out beyond the reach of what is ordinarily considered quick transit, and are building homes amid rural surroundings. An automobile, even



Sometimes the owner of a fine new house in the country will convert an old barn into a garage

Wooden building used to house the car of one suburbanite who has business in New York

if it is a small one, is to be found in practically every back yard, and those who have no car now intend to get one shortly.

The reason for the certainty of their movements lies in the automobile alone, because science and economy have proclaimed and experience has proved that the laborer cannot live more than 1 hour away from his work. If in the absence of street cars or other transportation to take him to the railroad station, a man is obliged to walk 2 miles or more, which requires at least one-half hour in good weather, and added to this, another half hour is allowed on the train, the limit is reached. With an automobile to carry him to the station in 5 minutes, it would be possible, from the viewpoint of practical economics, to live 55 minutes by train from his work.

Society is being gradually forced north by the inexorable decree of business. Already the encroachments of trade have squeezed the millionaires out of their homes in lower Manhattan, and the trend has grown so pronounced within the past three years that its significance can no longer be hidden. Hard-headed capitalists, real estate experts and economists generally are assured that in the course of a decade Manhattan Island will contain very few individual homes. In that day, they predict with confidence, that the resident population of New York will consist of apartment and hotel dwellers, to say nothing of the tenement millions. The real homes will all be out in the adjacent country, and every man who can own one will do so. Along with the home, and an essential part of it, is the automobile.

Dr. Best's garage at Englewood, N. J. This is built of concrete and cost $445

Even at present, the important part played in this movement by the automobile is generally recognized. Take, for instance, the morning the accompanying pictures were taken. The representative of The Automobile and the staff photographer first went to the Fort Lee ferry where one of the boats from the Jersey side was about to make a landing. On the boat were 18 vehicles of various sorts. There was 1 furniture van, 2 small trucks, 5 automobile runabouts, 6 touring cars and 4 limousines and town cars. In nine of the automobiles there were ladies, living at various places in Northern New Jersey, who were coming over to New York in the driving rain for shopping and social calls. The superintendent of the ferry said that on a fine day all the morning boats carried full loads of automobiles from 10 o'clock until noon.

These ladies are as certainly and as irrefutably New Yorkers as if they were living on Riverside Drive or Fifth avenue. They retain their intimate hold on the old conservative element of society that still fights stoutly against the incursion of business and consequently maintains its outposts on Manhattan Island.

They patronize the great commercial establishments of New York with even more freedom than did their ancestors, for it is easier to travel from Englewood or South Orange to New York to-day, via a big, comfortable limousine, than it used to be to drive down to the shopping district from upper Fifth avenue.

The representative of The Automobile discovered a number of fine private garages while seeking information on this subject. Some of them cost large sums of money and others very little. Perhaps the best type of garage at reasonable cost that was found is the one built by Dr. Best, of Englewood, N. J. As the accompanying picture shows, it is located back of his residence and next to the tennis court. It is 14 feet square and is built of solid concrete based upon broken blue-rock. This garage cost Dr. Best $445, and is ample in size and convenient.

Garages of wood cost various sums, and one of those shown herewith, of the same size as Dr. Best's, cost $800, while the one with the tiled roof cost $1,200.

Many suburban residents ride all the way into the city in their cars. Of course this does not mean that the owner goes all the way to Wall street through the mazes of traffic, as a general thing. Occasionally such practice is used, but in the vast majority of instances where the car is driven within the city, the owner alights at some subway station and continues his journey via the tubes. In such cases the car is usually garaged nearby until the owner is ready to return home.

In the vicinity of 181st street, 145th street, 96th street, 72d street and Columbus Circle, the garages do a considerable and growing business of this character.

Living out in the country and doing daily business in the city will not save much money, if it saves any at all. The situation as it stands is hardly one of choice for the New Yorker. He is forced to move away by a power which he cannot control.

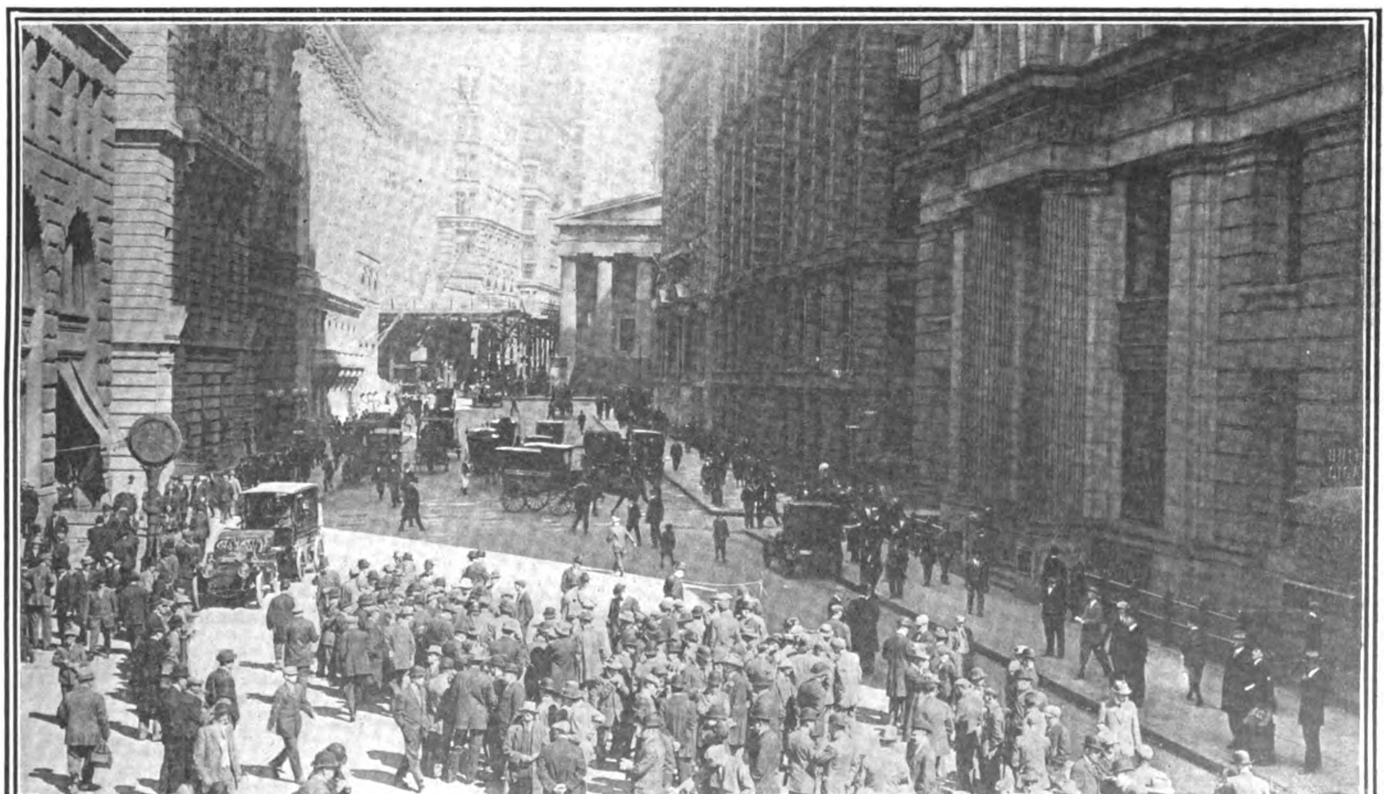
Take a typical case as an illustration: The head of the family earned a salary of $5,000 a year and the family consisted of himself, wife and two half-grown children. They lived in one of the fine apartment houses on upper Broadway and paid $65 a month for rent. They employed one servant at $30 a month, and their living expenses, administered with care and economy, averaged $150 a month. Incidentals called for $25 a month more and transportation, amusement, clothing, insurance and the education of the children accounted for $160 a month. The total yearly expense of this family, therefore, was $160 more than the total earnings of the provider.

Fortunately, the family had some other resources, and when the true significance of the situation was understood and it was realized that the children were growing up under appalling conditions and that value was not being received for the tremendous outlay in all directions, it was determined to move out into the country. This family selected a location out on Long Island

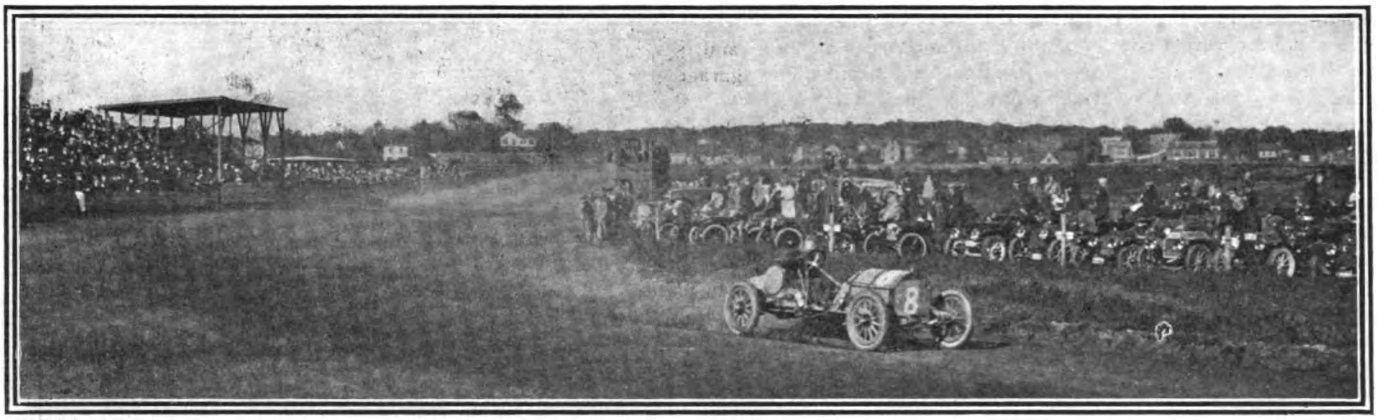
Many New York business men lend a touch of the artistic to the building of their garages

and invested $6,500 in building a home. The site is 6 miles from a railroad station, and so an automobile was found necessary. This cost $2,500. Living expenses were only slightly decreased, but a considerable item was saved in general and incidental expenses. At the end of the first year the family discovered their financial situation to be about as follows: Interest and taxes on home and car, $540; living expenses, $1,650; general and incidental expenses, $1,500; service, $300, and the cost of operating and maintaining the car, $930. This gave a total of $4,920.

As an actual economy in money terms this means only $240 a year; but, on the other hand, the family has an infinitely better home, and the children, instead of being cooped up with hundreds of others at home and jammed together with a miscellaneous assortment at school, are attending a select institution near at hand and living out-of-doors most of the time under ideal conditions for their physical well-being.



Broad street, in New York's financial center. Most of these curb brokers live in the suburbs and own cars



De Palma in Mercer, No. 8, leading the field in the five-mile race for non-stock cars under 301 cubic inches

Short Program at Guttenberg

THE Guttenberg track races were run off according to schedule last Saturday in spite of the rain which fell the day before the race. The track had dried under the influence of the wind and the warm sun and was in ideal condition for the races. The attendance was very good, a large number of those present coming in automobiles.

The races were well contested and furnished plenty of excitement for those who were clustered in the grandstand and in the enclosure. DePalma proved to be the chief attraction in his endeavors to lower the existing records for the track, which is a 1-mile dirt course of elliptical shape.

The 5-mile non-stock event for private owners proved to be the most closely contested race. There were three Regal cars entered, each driven by its owner. Sam From led the field on the first lap but was gradually overhauled by Ira Vail, who won the money. This event was the last of the contested races as after De Palma had lowered the track record for the mile, the 5-mile free-for-all was scheduled and that ended in an accident.

There were three entries in the free-for-all—De Palma in a Mercer, Grey in a Schacht and Koopman in a National. De Palma got away first but close on his heels was the National which clung to the inner edge of the track. The first lap was circled with these two far in the lead and the National car slowly creeping up. When the second lap was started they were so close that all those assembled rose to their feet to watch the speeding cars. The end of the ellipse was reached and both cars swung around the turn, the National just behind the Mercer. The Mercer car had just about reached the straighter part of the course when a cry went up. The National car had struck the inner edge of the track and bounded high in the air, revolving as it fell and striking the ground upside down. Koopman was pinned beneath the upturned car, while his mechanician lay in a pool of blood alongside the track. Both were picked up and carried away from the blazing car to the field hospital. The car was badly smashed, especially the front axle and the steering gear. The damage to the motor was comparatively slight. The injuries to the crew of the damaged car are feared to be serious, although not necessarily fatal.

The program was concluded by a 5-mile exhibition race against time by De Palma in a Simplex. He broke the Guttenberg track record for this distance. The summaries:

Five Miles, Non-Stock, Class E, Under 231 Cubic Inches

No.	Car.	Driver.	Time.
5	Paige-Detroit	Bill Regan	6:28 3-5
4	Regal	Chas. Tate	6:33 3-5
11	Regal	Emery Smith	6:58 3-5

Five Miles, Non-Stock, Class E, Under 301 Cubic Inches

No.	Car.	Driver.	Time.
8	Mercer	Ralph DePalma	5:38 1-5
3	E. M. F.	Jack Towers	5:45 2-5
6	Schacht	J. M. Grey	6:07 2-5
5	Paige-Detroit	Bill Regan	....

Five-Mile, Non-Stock, for Private Owners

No.	Car.	Driver.	Time.
12	Regal	Ira Vail	6:40 4-5
10	Regal	Sam From	7:05 1-5
11	Regal	Emery Smith	....

Five-Mile, Free-for-All

Not finished owing to accident to National car driven by Koopman.

Mile Trial for Track Record (0:59 2-5)

Car.	Driver.	Time.

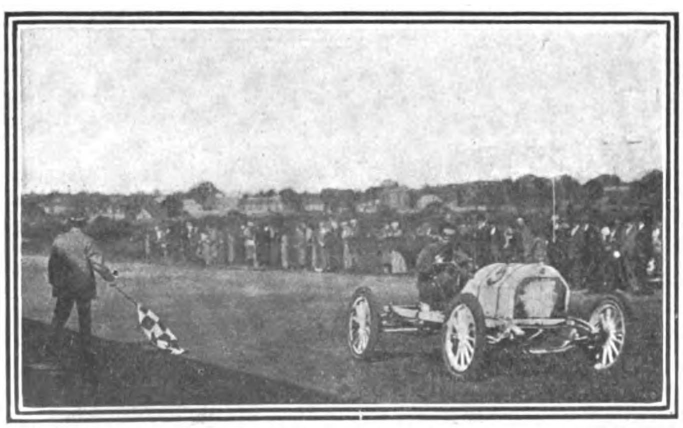
Five-Mile, Time Trial for Track Record (5:20)

Car.	Driver.	Time.
Simplex	DePalma	4:51 1-5



Paige-Detroit, No. 5, winning the five-mile race for small cars

Truck Test at the Golden Gate

SAN FRANCISCO, Sept. 26—The first motor truck test projected in northern California is to take place here October 4-5. Already more than a score of big machines have been entered in the contest, and the greatest interest is displayed among the dealers who have truck interests. The White Company alone has entered five trucks.

The first day's run will be from San Francisco down the peninsula to San Jose and return, a total distance of a little under 100 miles. On the second day the cars will remain within the boundaries of the city. It does not appear that the test is going to be very strenuous, plenty of time being permitted for the San Jose run on the first day and for the distance to be negotiated on the following day.

Inquest at Syracuse

SYRACUSE, N. Y., Oct. 4—The New York State Fair Commission, driver Lee Oldfield, the American Automobile Association, Referee A. R. Pardington and the crowd were held by the Coroner's jury to have been guilty of negligence at the inquest to-day in the matter of the recent terrible fatality at the State Fair track, when the Knox automobile driven by Oldfield crashed through the fence and killed eleven persons and injured nine. Nobody, however, was found sufficiently culpable to justify charges of manslaughter, and Oldfield, who had been under technical arrest, was released.

The evidence adduced showed a dispute between Lee Oldfield, the driver, who early this week had completely recovered from his injuries and left the hospital, and Manager Moross regarding the responsibility for his remaining in the race after it was known that his tire had gone bad. The tread of one of De Palma's Simplex tires had come off when the Italian was leading in the 50-mile race by a mile. Oldfield's testimony was to the effect that he was signaled to keep on in the hope that De Palma's tire would burn out and allow Oldfield to take the lead. Moross denied this, and said that Oldfield kept on on his own responsibility.

The evidence further showed police protection that might have been looked for at a half-mile track in the country districts. The policing was in charge of a clerk in a meat store. With 30 men assigned to him, he accounted for 14. The original plan had been to police the track with 125 regular and special police and with a militia detachment from this city. The militiamen left the grounds before the accident. The police that remained mostly mingled with the crowd, and with onlookers grabbed for souvenirs after a previous accident to Burman's Blitzen-Benz. A picture taken by an amateur photographer, just before the accident, showed the crowd encroaching upon the course at the fatal turn.

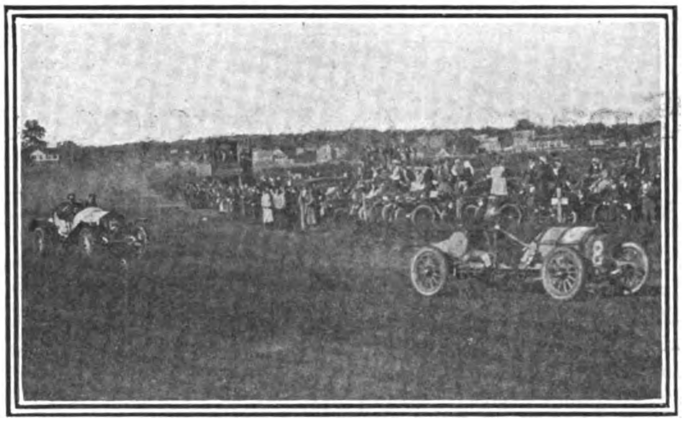
An important witness was A. R. Pardington, of The A. A. A., referee of the races. Mr. Pardington declared emphatically that he believed Lee Oldfield to be the right name of the responsible driver. Mr. Pardington said that if Lee Oldfield had perjured himself in taking out a license under a name not his own, that the fraud would have been discovered ere now and his license revoked. Mr. Pardington added that the reason the races were not stopped immediately was because to have done so would have been to precipitate a disastrous panic.

It is said on excellent authority that the surviving relatives of the deceased will soon bring actions for financial redress against the State.

Track Racing for Columbia, S. C.

COLUMBIA, S. C., Oct. 2—Two days of automobile racing will be presented to automobile enthusiasts of this section on November 3-4, when the meeting promoted by the Automobile Club of Columbia is held at the State fair track. The affair has been fully sanctioned and purses aggregating $1,325 hung up.

The races range from mile trials to 25-mile free-for-alls. No stock car races have been carded, the classes being C and D. A handsome piece of plate is offered for the mile trials. Entries close October 27.



Mercer leading the National in the free-for-all at Guttenberg

Local Mile Record Falls at Bridgeton

BRIDGETON, N. J., Oct. 2—The South Jersey mile record on a half-mile track was broken Saturday afternoon by a Kline (Morton), which made the double circuit in 1:15. The races were well contested and proved interesting despite the small fields. The stands and paddocks were fairly filled with 2,500 enthusiasts. The summary:

Car	Driver	Position	Time
Five-Mile Handicap			
Kline	Menker	1	7:30
Hudson 20	Luinney	2	
Five-Mile Handicap			
Kline	Menker	1	6:37 4-5
Knox	Dinapoli	2

Start of the five-mile race at Guttenberg, for private owners, in which three Regal cars contested—won by No. 12, driven by Ira Vail

Spaces Awarded at N. A. A. M. Shows

NEW YORK, Oct. 4—At the meeting of the N. A. A. M., held at the headquarters of the association this afternoon, positions were drawn for next winter's Chicago and Palace shows. Ninety-six makers drew for space at the Chicago pleasure car show, January 27 to February 10, of whom forty-seven were assigned places in the Coliseum, eighteen in the Coliseum basement, and thirty-one in the First Regiment Armory. The companies were divided into three general classes. The first of them was composed of members of the National Association of Automobile Manufacturers; the second, of members of the Automobile Board of Trade, who were not members of the National Association, and the third class included the independents.

The first class was divided into sections marked off by the amount of business the companies did, and the number of shows they participated in. Each class was exhausted before the next class was taken up. Space was awarded on that basis as follows:

COLISEUM—A1 Winton; A2 Rambler; A3 Franklin; A4 Buick; A5 Marmon; A6 E-M-F; B1 Woods; B2 Locomobile; B3 Lozier; B4 Hudson; B5 Reo; B6 Oldsmobile; C1 Packard; C2 Pierce-Arrow; C3 Stevens-Duryea; C4 Chalmers; C5 National; C6 Pope; D1 Maxwell; D2 Stoddard-Dayton; D3 Premier; D4 Cadillac; D5 Overland; D6 Peerless; E1 Brush; E2 Thomas; E3 Pullman; E4 Knox; F1 Columbia; F2 White; F3 Haynes; F4 Corbin; G1 Everitt; G2 Hupp; H1 Oakland; H2 Stearns; J1 Matheson; K1 Mitchell; L1 Abbott-Detroit; M1 Alco; N1 Cole; O1 Elmore; O2 Baker Electric; P1 Ohio Electric; Q1 American; Q2 Selden; Q3 Glide.

FIRST REGIMENT ARMORY—A1 Hupp Corporation; A2 Waverley; A3 Columbus; A4 Interstate; B1 Marquette; B2 Moline; B3 Rauch & Lang; B4 Case; C1 Garford; C2 Detroit Electric; C3 Simplex; C4 Cartercar; D1 Jackson; D2 Regal; D3 Austin; D4 DeTamble; E1 Kissel; E2 Staver; E3 Krit; E4 Cunningham; E5 Great Western; E6 Fiat; F1 Clark-Carter; F2 Imperial; G1 Babcock; G2 McIntyre; G3 Auburn; G4 Paterson; G5 McFarlan; G6 Moon; H1 Dorris.

BASEMENT OF COLISEUM—1 Stutz; 2 Elkhart; 3 Cino; 4 Borland; 5 Broc; 6 Halladay; 7 Warren-Detroit; 8 Zimmerman; 9 Michigan Buggy Co.; 10 Lion; 11 Buckeye; 12 Speedwell; 13 Ohio; 14 Marion; 15 Republic; 16 Paige-Detroit; 17 Crow; 18 Schacht.

Accessory spaces in the Coliseum number 135 and the M. & A. M. have contracted for all; besides there are several members over and above who have applied for space. In the gallery of the Armory there are 30 spaces to be divided among 70 applicants, not members of the organization. For the truck week the preliminary showing is so strong that already it has been determined to use both the Armory and the Coliseum for the commercial display.

The drawings for spaces in the commercial show, which is scheduled for the second week, are as follows:

COLISEUM—Section A, Baker, Rambler, Mack; Section B, Reo, Kelly, Pope, Rapid, Grabowsky; Section C, Franklin, Stearns, Cartercar, Waverley, Packard and Locomobile; Section D, Peerless, Brush, Gramm, Metzger, Knox; Section E, Alco, Detroit Electric, Schmidt; Section F, Kissel, Pierce-Arrow; Section G, Reliance; Section H, General Motors; Section J, Staver; Section K, Lozier; Section L, McIntyre; Section M, Avery; Section N, Rassel, Federal, Adams; Section O, Eclipse; Section P, Clark, Sampson; Section Q, Dorris, Dayton, Durant-Dart; United States Motors Company.

FIRST REGIMENT ARMORY—Section A, Stegeman, Walker; Section B, Packers, Smith, Coleridge, Lauth-Juergens; Section C, Sternberg, Lee; Section D, National, Universal; Section F, Schacht.

The result of the drawings for space in the show at the new Grand Central Palace, January 10-17, follows:

MAIN FLOOR—Section A, Paterson, Velie, Ohio Electric, Imperial, Cutting, Waverley; Section B, Hupp Corporation; Section C, Paige-Detroit, Ames; Section D, Fiat, Cole; Section E, Marion, Stutz, Krit; Section F, Hupmobile, Warren-Detroit; Section G, Babcock Electric; Section J, KlineKar; Section K, Abbott-Detroit; Section L, Cino, Colby; Section M, Rambler, Regal, Schacht, Auburn, DeTamble; Section N, Lion, Middleby; Section O, Great Western, McFarland.

SECOND FLOOR—Section A, Elkhart, Crow. All the remainder of the exhibits on this floor are trucks, as follows: Gramm, Waverley, Schacht, Lauth-Juergens, National, Packers, Kelly, Durant-Dort, Eclipse, Universal; Section B, Sanford, Newark; Sections D and E, Atterbury; Section F, Walter, Dayton, Raffel; Section J, Sullivan, Lippard, Cortland.

The new Grand Central Palace is a giant structure, being bounded by Lexington avenue, Forty-sixth and Forty-seventh streets and Depew place. The floors that will be used for show purposes are the main, second and third. A court extends from the main floor to the ceiling of the third and the dome-like roof over this portion of the hall is supported by Corinthian columns of ornate structure.

The interior of the building is considerably cut up by pillars and it is problematical still how far this type of architecture will lend itself to automobile show purposes. But it is artistically beautiful. The pillars will not interfere with the showing of particular exhibits, because the space is ample and access from all sides will be easy, but it will be impossible to get any such general view of the display as is afforded by the arrangement of Madison Square Garden.

A grand stairway leads up to the main floor from the street level and the first impression of the hall is that of vastness. The rather low ceiling adds to this impression, paradoxical as that may seem. The pillars are in several styles, ranging from the Corinthians with their decorative capitals to square, business-like columns that are simply utilitarian.

The second floor is arranged around the court, with a large amount of space available on the Lexington avenue side, while there is still more room for exhibits on the third floor, due to the partial closing of the court. Each floor is approximately 194 by 268 feet, thus without making allowances for the court and various portions of each floor that are not available for show space, the total area of the three floors is 155,376 square feet. Probably 25,000 square feet should be deducted from this total to make allowance for space used otherwise than for show purposes.

The decorative scheme will be mosaic, but its details still remain to be worked out. Mr. Miles declares that any such scheme of decoration as has been used in many of the big shows of the past would seem like painting the lily, as applied to the palace. The ornamentation will undoubtedly be simple so that it will not detract from the architectural beauties of the building.

Some progress has been made in the details of the Madison Square Garden show, but the work is moving slowly. It is not likely that floor plans will be issued for several weeks. The Motor and Accessory Manufacturers have announced that about 150 of their members would show at the Garden during the week when the pleasure cars are on exhibition. Fully ninety M. A. M. members will show during the truck week at the Garden.

Automobile Aids Carriage Builders

ATLANTIC CITY, N. J., Sept. 30—The thirty-ninth annual convention and exhibition of the Carriage Builders' National Association were held on Young's Million Dollar Pier during the past week, the exhibition extending throughout the entire week, from Monday to Friday, inclusive, and the convention proper covering a period of two days, Tuesday and Wednesday, when the regular business of the association was taken up and officers elected for the ensuing three years. Delegates were present from all over the country and the industry was shown to be in a flourishing condition, despite the inroads made by the horseless vehicle. Rather, as E. C. Mulcey, of Philadelphia, in an address on "Electricity as Related to the Vehicle Industry" said, the use of the automobile has broadened the scope of the wagon and carriage builders' art and brought to carriage and wagon manufacturers new fields for the sale of their product, and suggested the amalgamation of wagon and carriage builders with experts on engines, electric motors, storage batteries, etc., to their mutual advantage. Disclaiming the idea that the automobile was a competitor opposed to the vehicle builder's interest he asserted that the former was strictly a branch of vehicle building and a development of that art brought about by the demands of modern times.

President Charles J. Richter's address to the delegates on Tuesday dealt with the future of the carriage and during the course of his remarks he said that although the carriage has been largely superseded by the horseless vehicle in the large centers of population, there is still a steady demand for the horse-drawn carriage, and claimed the light horse-drawn pleasure carriage will always have its devotees.

The consensus of opinion among the speakers was to the effect that automobile manufacturers and wagon and carriage builders should work together, their interests being identical in many respects.

Headquarters of the convention while in Atlantic City were established at the Marlborough-Blenheim. where also the annual banquet was held.

The following officers were elected: President, William H. McCurdy, Evansville, Ind.

Secretary-Treasurer, Henry C. McLear.

Trustee of Technical School, William R. Innes, New York.

Executive Committee, Charles C. Hull, Connersville, Ind.; Charles H. Lancaster, Merrimac; George A. Brockway, Homer, N. Y.; C. O. Wrenn, Norfolk, Va.; W. A. Sayres, Cincinnati, O.

In number and variety of exhibits of vehicle parts the exhibition was up to previous shows and the attendance excellent.

The following manufacturers and jobbers of automobile accessories were represented at the exhibition and had displays:

American Tire Drill Company, Cincinnati, O.—Motor-driven and belt driven tire drilling machines.

Backstay Machine & Leather Company, Union City, Ind.—"Never-Burst" wire-bound prop blocks, patent valances for stitching on tops, patent auto top tack valance, auto straps, etc.

D. W. Byron & Sons, Williamsport, Ind.—Leather for automobile, carriage and furniture manufacturers.

W. H. Coe Manufacturing Company, Providence, R. I.—Coe's ribbon gold leaf and gilding wheels, for striping, lettering and decorating automobiles, carriages and wagons.

Consolidated Rubber Tire Company, New York City—Kelly-Springfield sectional truck tires and solid carriage tires.

Cortland Forging Company, Cortland, N. Y.—Auto top and buggy forgings.

Crandal, Stone & Company, Binghamton, N. Y.—Bow sockets and top hardware for automobiles and carriages.

Ditzler Color Company, Detroit, Mich.—Automobile, coach and car colors.

Dusenbury, Louis & Company, Inc., New York—Automobile and carriage upholstering, automobile top fabrics, etc.

Eberhard Manufacturing Company, Cleveland, O.—Automobile, carriage and wagon hardware.

Eccles Company, Auburn, N. Y.—Automobile forgings, etc.

Enterprise Brass & Plating Company, Cincinnati, O.—Robe rails, dash rails, arm rails, handles.

Excelsior Seat Company, Columbus, O.—Automobile seats, runabout seats, etc.

Fabrikoid Works, E. I. duPont de Nemours Powder Company, Newburgh, N. Y.—Artificial leather and automobile top goods.

Fairfield Rubber Company, Fairfield, Conn.—Full line of automobile and carriage cloths.

Herbrand Company, Fremont, O.—Automobile wrenches, etc.

Goodyear Tire & Rubber Company, Akron, O.—Wing and eccentric cavity cushion tire rubber.

Gramm Motor Truck Company, Lima, O.—Five-ton chassis, three-ton chassis, etc.

Liggett, Spring & Axle Company, Pittsburgh, Pa.—Automobile springs and axles, brass fittings for automobiles.

Metal Stamping Company, Long Island City, N. Y.—Automobile trimmings and hardware, etc.

Mohawk Valley Manufacturing Company, Utica, N. Y.—Automobile mufflers, etc.

Muncie Wheel Company, Muncie, Ind.—Automobile wheels, etc.

Rogers & Company, Inc., Philadelphia, Pa.—Limousine and touring car trimmings, brass goods, etc.

Rose Manufacturing Company, Philadelphia, Pa.—Neverout lamps.

Sheldon Axle Company, Wilkes-Barre, Pa.—Axles and springs for power-propelled and horse-drawn vehicles.

Smith & Company, New York—Automobile and carriage color varnishes, etc.

Standard Varnish Works, New York and Chicago—Quick finishes for automobile and carriage bodies.

Swinehart Tire & Rubber Company, Akron, O.—Motor buggy tires, clincher and flange truck tires, etc.

Western Spring & Axle Company, Cincinnati, O.—Comprehensive line of springs and axles for both auto and horse-drawn vehicles.

Woll & Sons Manufacturing Company, Philadelphia, Pa.—All grades of curled hair for automobile and carriage upholstering.

Big Plans for Hartford Show

HARTFORD, CONN., Oct. 2—The Automobile Club of Hartford has decided to hold its 1912 show February 19 to 24, in the new state Armory, which has a larger floor area than Madison Square Garden. The main floor of the big hall gives an area of over 50,000 square feet for the exhibit of cars and accessories, while there are numerous side rooms, drill rooms, etc., which bring the total available space to practically 65,000 square feet.

The tentative decoration plans call for a big outlay of money. To place the sky bunting over the vast iron-girded ceiling will cost alone about $1,000. The whole hall will be profusely decorated. The outlay of the spaces call for a wide aisle on the four sides of each exhibit.

The work on the show has already started under the direction of Fred W. Dart and E. G. Biddle, and as soon as the sanction is received the plans will be rapidly pushed ahead.

Half-way down Sweetbrier Hill, the most dangerous place on the course

Fairmount 200-mile

PHILADELPHIA, Oct. 3—The entry list of the Fairmount Park road race closed at midnight last night and although the total falls eleven shy of the limit set by the Contest Committee of the Quaker City Motor Club, and thirteen below the number participating last year, the contest is expected to be none the less thrilling on that account and indications point to all attendance records being broken. There are nineteen cars entered, representative of eleven separate makes.

Five last-minute entries were made yesterday: two Bergdolls, an Ohio, a Mercedes and a Fiat.

Preliminary practice trials are being held each morning between sunrise and 7.30, twelve drivers having had their cars out this morning, quite a large crowd being present to look on. A heavy rain put a quietus on the spins Monday morning, the track being very soft, and although five drivers were on the ground, none ventured the heavy going. These trials will continue every morning until the day of the race.

The race long since ceased to be strictly a local affair, and visitors are expected from not only all over Pennsylvania, but from many of the adjoining States as well. Of course, there is no way by which an accurate count could be made of the thousands upon thousands that line both sides of the 8-mile course from one end to the other and that storm the turns where thrills may be expected, but putting last year's attendance at approximately 500,000, judging by the increasing interest this classic takes on yearly, it is not overstating the facts to say that 750,000 will see next Saturday's race.

Reserved seats and boxes have been eagerly snapped up almost as soon as placed on sale and the advance demand for parking spaces has been unprecedented. Proceeds of the race are divided equally between several of the city's charitable and philanthropic institutions.

Police regulations governing the course will, as in former years, be adequate, the number of guardians on duty numbering at least 2,000. Officers will be stationed about 20 feet apart, with an augmented guard at the turns. At points regarded as dangerous and at particularly sharp curves, the rule keeping spectators at a safe distance from the road, in some instances from 25 to 50 feet back, will be strictly enforced.

Regarding the race itself, many old favorites will be seen, with a liberal sprinkling of drivers who have become famous on other tracks. But there is an additional curiosity attached to the veterans of other Fairmount Park races this year in that few of them will be identified with the cars with which it has become the habit of associating them.

Thus, Len Zengel, who piloted a Chadwick to victory last year in the closest race ever witnessed here, will be at the wheel of a National. Ralph Mulford, the runner-up last fall, will as then drive a Lozier, but rumor has it that he will be found at the wheel of another make before long. Harry Grant, twice winner of the Vanderbilt cup, will also drive a Lozier, with which car he has been identified since the American Locomotive Company dropped racing. Erwin Bergdoll is about the only other driver who will use the same car, he having again nominated the Benz. Newcomers include Charles Basle, Cole; Lee Oldfield, Fiat; Joe Jagersburger, Case; Gil Anderson, Stutz; Harvey Ringler and Hughie Hughes, each driving a Mercer, and many others.

Cars will run in five classes, divisions 2-C, 3-C, 4-C, 5-C and 6-C, a prize of $1,000 is hung up in each, with a grand prize of $2,500 for the car making the best time. In addition this year prizes of cash will be awarded by the Remy Magneto Company to the first, second and third cars, Remy-equipped, in the

Will Draw Big Crowd

various divisions. Findeisen & Kropf, on behalf of the Rayfield carbureter, have offered $200 in each of the classes for winning cars carrying Rayfield carbureters.

Contest will start at 12 o'clock noon. The course covers about 8 miles, the start and finish being at Memorial Hall, around Sweetbrier Hill, north on the West River Drive, to city line, to Belmont avenue, to start.

The complete classified list of entries is as follows:

Car.	Bore.	Stroke.	Entrant.	Driver.
Division 3-C—231 to 300 Cubic Inches Piston Displacement				
Ohio	4 15/32	4¼	Ohio Motor Car Co.	S. H. Matthews
Ohio	4 15/32	4¼	Ohio Motor Car Co.	George P. Parker
Cole	4½	4½	Cole Motor Car Co.	Charles Basle
Mercer	4⅜	5	Mercer Automobile Co.	Harvey Ringler
Mercer	4⅜	5	Mercer Automobile Co.	Hughie Hughes

Fiat	130mm.	190 mm	J. Fred Betz, 3d.	J. Fred Betz, 3d.
Benz	155mm.	160mm.	Erwin R. Bergdoll	Erwin R. Bergdoll
Fiat	130mm.	190mm.	Frank S. Hodson	Lee Oldfield

L. I. A. C. to Attend Fairmount Race

BROOKLYN, N. Y., Oct. 2—Extraordinary preparations are being made by the Long Island Automobile Club to attend the forthcoming road race at Fairmount Park, Philadelphia. The club has arranged for a special train over the Central Railroad of New Jersey, leaving New York at 8:50 o'clock in the morning, October 7, and reaching the park at 11:15. Present indications point to a delegation of at least 100. Accommodations in one of the grandstands are the subject of negotiations, and if these are secured the Brooklyn party will be kept together during the running of the race.

The return trip will be from the Reading terminal at 7 o'clock, and the train is scheduled to arrive in New York at 9 o'clock.

Massaging Grand Prix Course

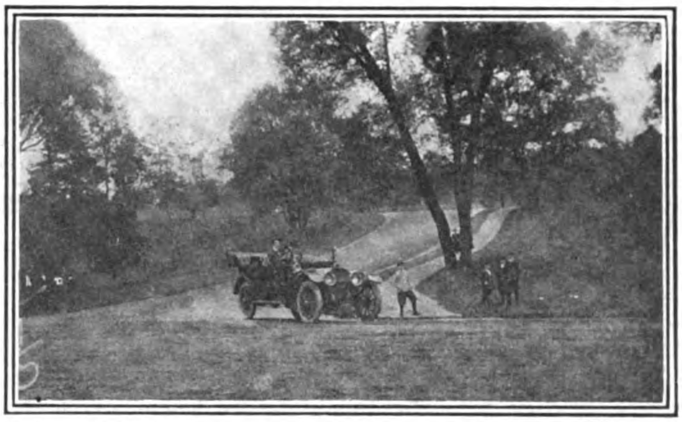
SAVANNAH, GA., Oct. 2—Work on the course to be used for the four big road races next month is progressing satisfactorily. The new paving which joins Norwood and La Roche avenues and upon La Roche avenue to Dale avenue and through the latter to Waters road has been completed. Waters road will probably be finished in two weeks and the rest of the circuit will then be taken in hand.

Whitfield, Ferguson and Norwood avenues constitute the bulk of the uncompleted work, but the whole course should be finished and in better condition than ever before by November 5.

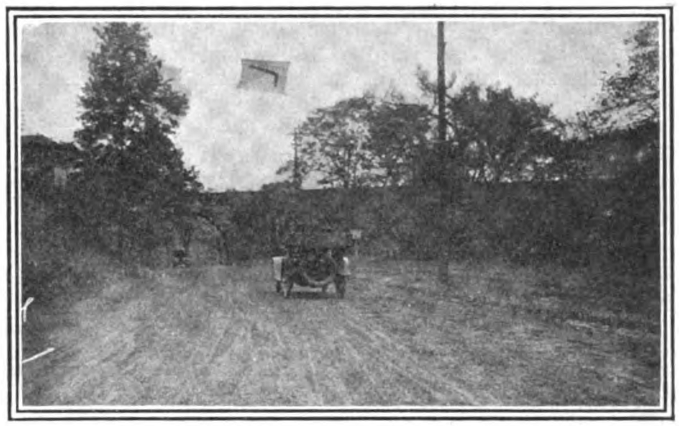
Some of the drivers who will take part in one or more of the races are as follows: Bruce-Brown, Parker, Tetzlaff, Nazarro, Bragg, Hemery, Burman, DePalma, Knipper and Hearne.

The Fiat company will have a team of five; the Benz company, three; Cole, three, and various other companies will be represented by from one to four cars. Definite formal entries for the events are not numerous so far.

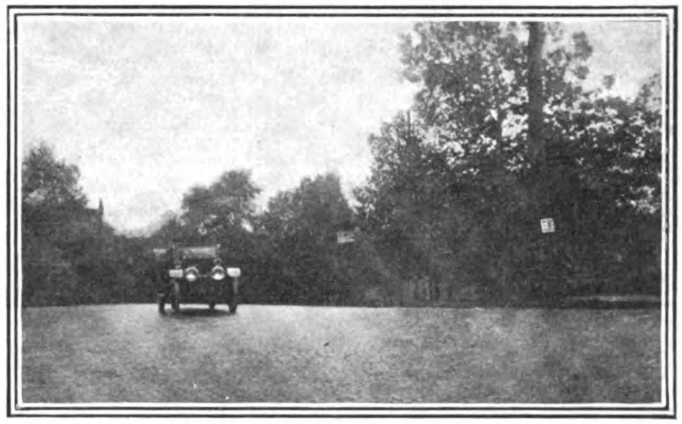
It is estimated that there will be about eight cars in each of the light car races and twenty-five cars in the Vanderbilt Cup. The Grand Prix estimate is placed at twenty cars.



At the foot of Sweetbrier Hill—making the turn into the West River Drive



West River Drive, with bridge spanning roadway and Schuylkill



52d Street entrance, where course leaves Park and follows a city street

Glidden Tour to Have 83 Starters

WITH a total list of 83 cars, the Glidden Tour of 1911 will start on its journey Saturday morning, October 14, from a point on Fifth avenue, probably in front of the new public library. There will be 73 cars in the contesting column, but the make-up of the various teams has not been crystallized so far.

The main trophy will be awarded to the team with the least number of demerits at the conclusion of the tour and penalties will only be imposed for lateness at controls. The daily schedules are easy as far as mileage is concerned, and but for bad weather it would appear that a large number of clean scores must result. However, no allowance will be made for tire troubles and in case of bad roads aggravated by bad weather the clean score list will be reduced materially.

The complete entry list is as follows:

Entrant	City	Car
C. S. Winn	Atlanta	1912 Flanders
John S. Cohen	Atlanta	1912 White
J. H. Marstellar	Roanoke	1910 Chalmers

Buckeye Suggests Good Roads Plan

COLUMBUS, OHIO, Oct. 2—State Highway Commissioner James R. Marker advocates co-operation on the part of the State and Federal Government as the best means to secure good roads.

He favors making provision in the coming constitutional convention for authority by the State to issue bonds to the amount of $5,000,000 annually. Such an outlay within fifteen years would give the State a perfect system of roads.

Commissioner Marker contends it would be far more beneficial for the Federal Government to put its spare millions into good roads instead of dumping it into the army and navy. In Ohio there are 90,000 miles of highway, 50,000 miles of rural free delivery and 8,000 miles of roads which would fit into an inter-county system.

Garford Train Starts to Los Angeles

Equipped for a transcontinental tour, four Garford touring cars and a baggage truck started from New York on Monday, headed for Los Angeles. These cars were joined at Albany Tuesday by a fifth touring car which started from Boston. When the party has progressed westward as far as Cleveland, another baggage truck will join the caravan. There are twenty-five passengers riding on this automobile train.

According to schedule, the train will reach Los Angeles in 51 days. The rate of fare is $875, which averages $16 a day covering everything. Raymond & Whitcomb are responsible for the venture. A. L. Westgard is in charge.

DAILY ITINERARY OF THE GLIDDEN TOUR OF 1911

Late Trade and General News

CHICAGO, Oct. 2—Sidney S. Meyers, chairman of the creditors' committee of the Maytag-Mason Motor Co., Waterloo, Iowa, has issued a statement to the creditors, requesting them to submit proof of debts to said company, so that the affairs of the company and the interest of the creditors can be placed within the jurisdiction of the United States district court.

This creditors' committee, appointed to investigate, found on July 1 assets, plant, equipment, merchandise, and all other ascertained assets to the extent of $331,000. At that date the direct liabilities on bills and accounts payable were $367,978.08. Contingent claims alleged to be due for breach of contracts and for other causes amounted to $70,000, making a grand total of liabilities of $437,978.08. Two-thirds of the actual assets are represented by unfinished motor car parts. It is estimated that the shrinkage in the value of these parts will be two-thirds of the book value.

There has been submitted by the company a tentative proposition of 33 1-3 per cent. for the unsecured claims, provided there shall be concluded a contemplated arrangement with Senator Maytag by which he shall take care of the secured claims.

Colonels Win Lamp-Sign Fight

LOUISVILLE, Oct. 2—On motion of A. Scott Bullitt, County Attorney, the cases against Louisville motorists, charged with violating section 4 of the State automobile law, requiring that the number of the State license be displayed on the lamps of the cars, were dismissed Thursday in Magistrate Vogt's court. Mr. Bullitt declared that, inasmuch as the Secretary of State had informed members of the Louisville Automobile Club that they need not observe that section of the law, and as no subsequent warning had been given the owners of motor cars, all cases should be dismissed.

The executive committee of the Louisville Automobile Club met before the court and made preparations for the cases. Resolutions were adopted which provided for the making of a case to test the validity of the law.

International Show in Berlin

BERLIN, Sept. 24—The first automobile show in Germany for 4 years will open in Berlin on October 12 and continue for 10 days. The show will be held under the auspices of the Imperial Automobile Club. The motor industry of eight countries—France, Germany, England, Belgium, Sweden, Switzerland, Italy and the United States—will be represented on the floor of the big exhibition pavilion.

More than 270 exhibitors have taken space and 67 factories will have cars on view; almost every model and type of car, both pleasure and truck, will be shown.

Mud Stalls Winnipeg Contestants

WINNIPEG, Oct. 2—Over 200 miles of road, saturated with rain and buried in mud, the fourth annual contest for the Oldsmobile Endurance trophy was run last week. In addition to this amount of rough going the route contained another 200 miles of pretty passable thoroughfare. The run was commenced Wednesday morning and while its completion was scheduled for the following night, some of the cars have not arrived back in the city.

The award of the judges will not be made until the technical inspection is completed this week. The cars returned in the following order: Ford, Paterson, Reo, Velie, Halladay, Empire, Chalmers and Hupmobile. The unaccounted cars are: Reo, Whiting and Halladay.

A. C. Emmett was pathfinder and Dr. F. W. Glasgow, judge.

Hoosiers Choose Their Directors

INDIANAPOLIS, Oct. 2—Directors of the newly organized Hoosier Motor Club, were elected at a meeting held at the Claypool Hotel in Indianapolis, on the night of September 30. Officers are to be elected on the evening of October 5, and temporary club rooms will be established in the Claypool Hotel. Directors of the new club are Charles A. Bookwalter of the Mais Motor Truck Company; H. H. Rice, of the Nordyke & Marmon Company; Charles W. Sedwick; H. O. Smith, president of the Premier Motor Manufacturing Company; Bert A. Boyd; C. L. Diers, of the Goodyear Rubber Company; Joseph W. Selvage, Homer McKee and Hiram Brown. There are about thirty-five charter members.

Harking Back a Decade

IN the issue of October 3, 1901, of *The Motor Review*, the following items were given prominence:

The First Annual Automobile Exhibition, under the auspices of the Chicago Automobile Club and the National Association of Automobile Manufacturers has been definitely fixed for March 1-8, 1902, at the Coliseum. This event will be the third automobile show to be held in Chicago.

Announcement is made that the E. R. Thomas Motor Compan, of Buffalo, has disposed of its motorcycle business to the Auto-Bi Company. The latter agree to use Thomas motors for its product. E. L. Ferguson is named as sales manager.

The annual meeting of the N. A. A. M. is set for November during the Madison Square Garden show.

Washington, D. C., Sept. 28, 1901—The first call for bids to furnish motor vehicles to the postal service has been made. The subject matter of the proposals was the equipment of the Minneapolis department with five 1,000-pound wagons.

According to an executive order of the Secretary of the Treasury, exports of automobiles will be made a separate head in the monthly reports of exports. Such exports have been included under the general heading, "all other carriages."

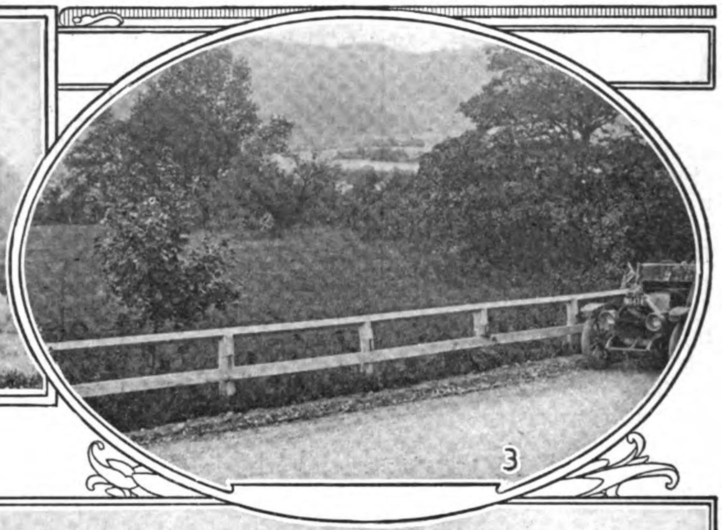
At the Fort Erie race meeting Henri Fournier in a Mors car broke the world's record for 25 miles on a circular dirt track, making the distance in 31:58 2-5. He also broke the mile record, flying start, in 1:13 1-4.

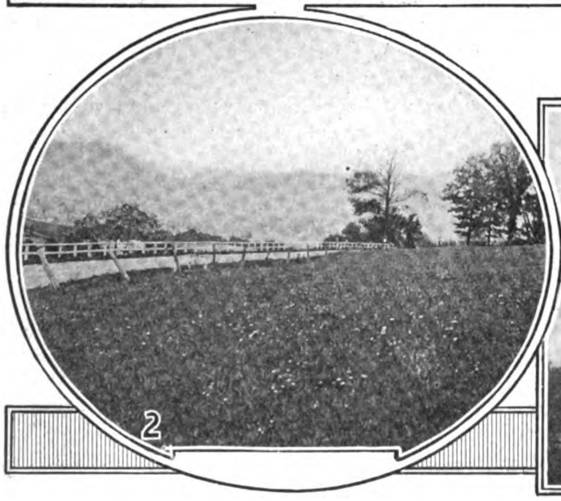
The Lane Motor Vehicle Company, of Poughkeepsie, N. Y., sent a letter of protest to the editor, objecting to the reports of the New York-Buffalo endurance test on the ground that they did not go into mechanical details.

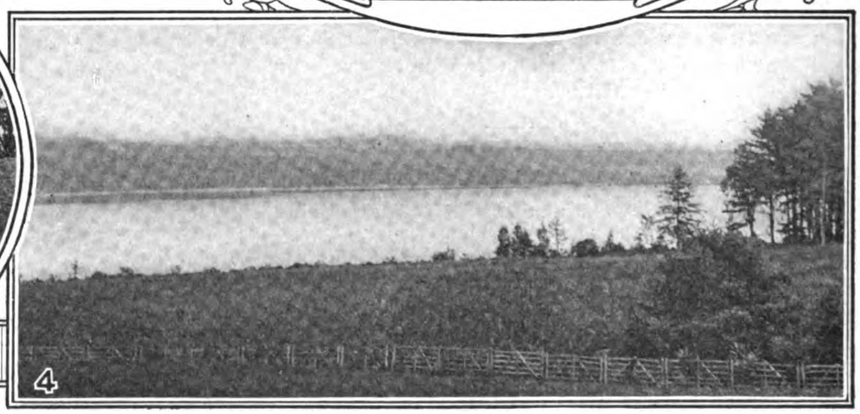
Bad roads are the subject of the leading editorial of the week and the experience of entrants on the endurance run is cited as an example of their condition in New York State. The roads beyond Albany are referred to as swamps.

C. C. Bramwell, in the feature article of the week, tells of the lessons to be learned from the endurance run. He said that the roads were worse than expected and blamed their condition on the farmer. He also calls attention to the practice of allowing manufacturers to enter as many cars as they please to the detriment of some of the smaller concerns that can enter but one or two cars.

Berkshire Hills in Autumn Splendor







1—Comprehensive road signs are scattered along where needed

2—Road over Lebanon Mountain, just east of Massachusetts line

3—Just a glimpse toward the southern hills from Pittsfield

4—A shimmering lake, high in the hills near Lenox

"WHEN the frost is on the punkin" there is no more beautiful section of the globe than the Berkshire Hills of Massachusetts.

Jack Frost, the master painter, does his inimitable work with the delicate hand of the artist. He avoids the bold line-work of the impressionistic school without losing an atom of its coloration. He selects a single tree, set in a galaxy of green, and in one night converts it from tender, verdant greenery into a blazing focus for the center of his picture, lighting up a whole mountainside with the brilliant yellows and glowing reds and touches here and there a spot with his Autumnal pigments to make the contrast more inspiring.

Long before the valleys and low-lying sections feel the breath of frost the Berkshires are aglow with brilliance like unto nothing to be met with elsewhere.

A leisurely trip through this section, using an automobile for conveyance, so that one may select his own points of view and loiter along if he so wishes, will repay whatever it costs a thousandfold.

There is everything to be found along the way in the whole category of scenery. From some of the hilltops the giant vistas through the rich valleys deserve the inspired efforts of the poet; the rugged mountains, softened here and there where the pine trees have smoothed out the harshness of their granite walls, are marvelously virile despite their miniature size as compared with the towering peaks and bleak aspect of the Sierras and Rockies; the little lakes and streams, clear as crystal, tumble noisily toward the ultimate ocean and lend a delightful variation to the picture panorama unfolded before the appreciative sight of the tourist; and the long, winding grades that lead to the lower levels complete the scene that has no equal in this part of the continent, if it has anywhere.

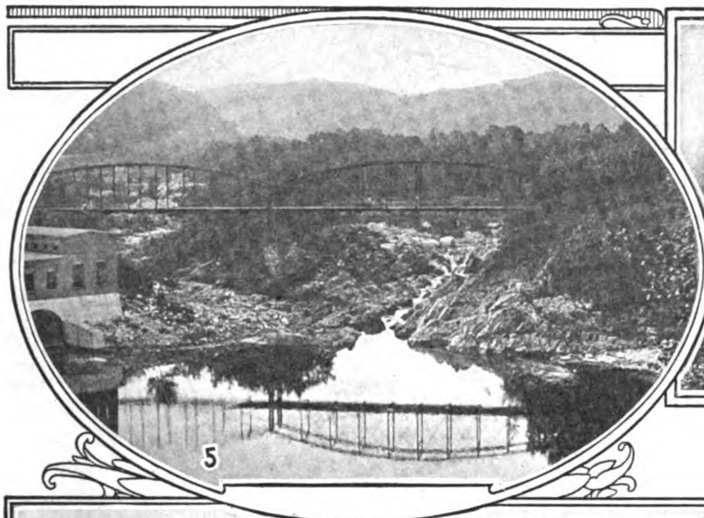
As the stage setting for an autumn honeymoon en automobile, the Berkshires are ideal. As a restful trip for the family, there is nothing like it to be found hereabouts. As a short respite for the businessman, it has everything that is necessary.

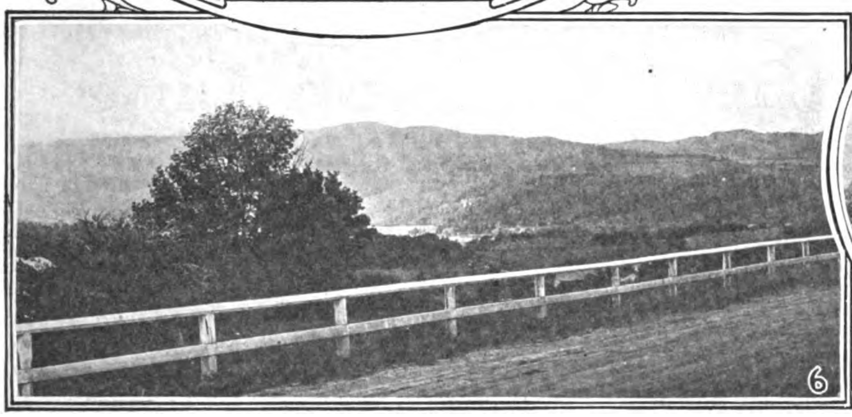
Given a good car, harmonious party and the present delightful first scene in the annual Indian Summer, and the perfect roads of New York and Massachusetts will do the rest.

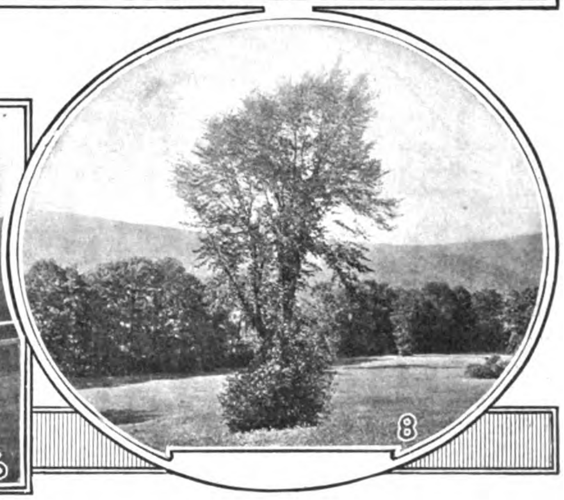
Starting from Albany, full details of the course having been received from the Albany branch of the Touring Club of America, which is located in spacious quarters in the Hotel Ten Eyck, the party proceeds eastward, crossing the river and heads for the blue foot-hills. There are a number of pretty detours that may be made before reaching Lebanon Mountain, which is close to the Massachusetts State line, but these are not important unless the party wishes to spend a comparatively long time in the tour.

Climbing Lebanon Mountain is a delight, long to be remembered if the new state road that skirts the hillside is used in making the ascent. The grade is stiff, but not unduly trying to any modern automobile. At the crest of the road, the party passes into Massachusetts. The transition is not marked by any radical change in road conditions, for where one state leaves

Offer Unusual Touring Opportunities







5—Spidery bridges give an Alpine tinge to the landscape

6—Varied scene typical of the section near Stockbridge

7—Granite ribs of the earth's body occasionally protrude

8—Greensward, hill and dale, on the way toward Pittsfield

off, the other picks up the work on similar lines and unless one noticed the signs that proclaim the state lines, the passage from one to the other would not be noticed.

From this point eastward lie the Berkshires and the run from Lebanon Mountain to Pittsfield is one of continuous beauty and change. It is only a short run in miles from Albany to Pittsfield, but it should be long in time because it deserves it. Fast time can be made for the roads are very perfect and magnificently kept, but it would almost seem like sacrilege to open up the throttle and miss a single picture.

Further details as to detours and lovely side trips are available at the Pittsfield quarters of the Touring Club of America at the Hotel Wendell. Of course, one wants to go over the celebrated Jacob's Ladder where only a few years ago a whole Glidden Tour stalled helplessly on the hillside. Most of the rungs have been pulled out of the ladder as it stands at present and the grades will not puzzle the average car in the least. Looking back at the old road over which the Glidden cars eventually passed, the impression of a ladder rising to heaven is not hard to receive. The old road has been eliminated by carrying the main highway around the other side of the hill and bringing it down to the grade of the state road at an easier angle.

The average tourist would pass by the old ladder if he were not watching for it. To-day it seems like an abandoned road through the woods, overgrown with underbrush and almost pathetic in its isolation.

The summit is reached just beyond this point and is decked with a monument around which are piled stones bearing the names and addresses of automobilists from every section of the land who have contributed more or less ornamental memorials to the monument.

From there clear to Springfield the way is general down grade and a slow, deliberate automobile trip will reveal more beauties to the mile than the vast majority of tourists even suspect of existence.

There is another station of the Touring Club of America at Springfield, located in the New Kimball, where road information for a continuance of the tour may be had freely. Connecticut affords a big and beautiful field; the northern central portion of Massachusetts is historic in interest and gorgeous in Autumn colors and dozens of other sections stand ready for exploration.

Just one word of repeated caution. Take your time, enjoy Nature in her most wonderful garb and when you get home again you will have an evergreen memory that contains nothing but delight.

Boost Good Roads with Bond Issues

San Francisco, Sept. 26—The people of Glenn County, in northern California, have shown their appreciation of the benefits of good roads by voting road bonds to the amount of $450,000, by a large majority of ballots. The bonds will be used for the building and improvement of 158 miles of roadway throughout the county, which is one of the smaller divisions of the State.

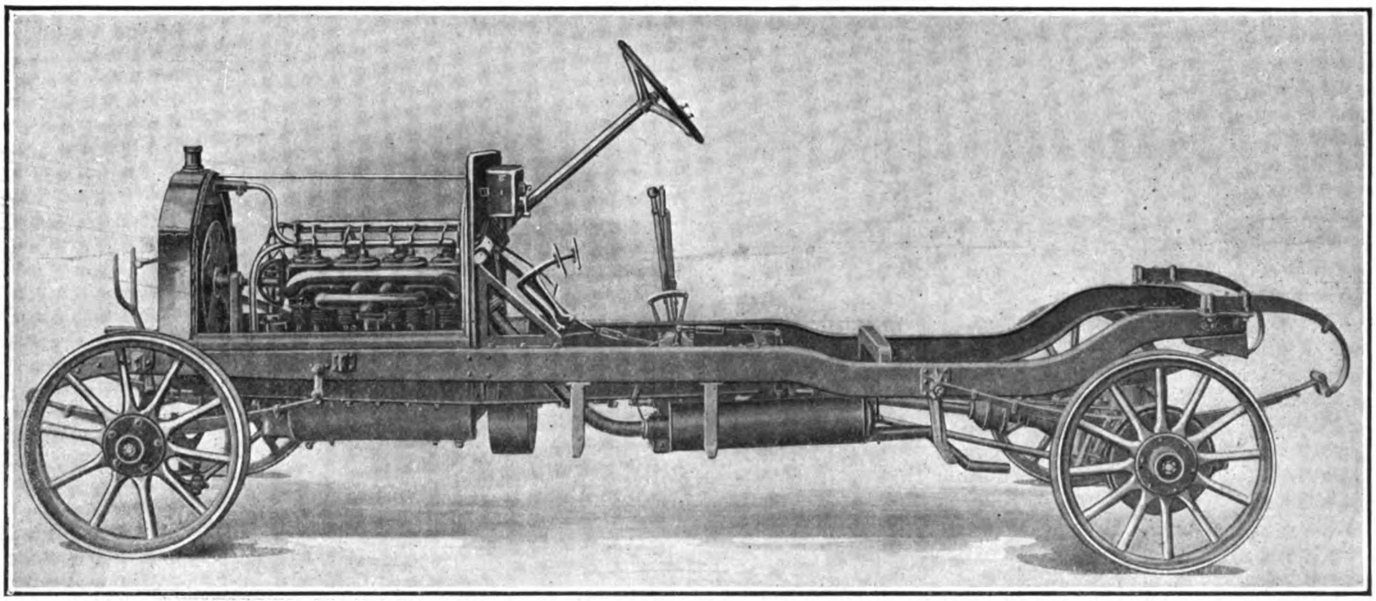


Fig. 1—Chassis used in connection with the Model F Lexington touring cars and coupé

Elucidating the Lexington Line

AMONG the most recent announcements of cars placed upon the market for the season of 1912 is that of the Lexington Motor Car Company, of Connersville, Ind. This company has confined its efforts to two styles of chassis and has fitted these with six styles of body, embracing five-passenger touring car, demi-tonneau, coupé and roadster types.

The two chassis are equipped with motors of different types, one being the Model X Rutenber and the other the Model R A Rutenber. The Model X motor is used in the D F touring cars and the Model E roadster in connection with the smaller chassis of the two. It is rated by the makers at 40 horsepower and has four single cylinders having a bore of 4 1-8 inches and a stroke of 5 1-4 inches. The inlet and exhaust manifolds N and M, Fig. 3, and the valves are located on the same side of the motor and are operated from the same camshaft. The cam action is made very accessible by the fact that the fulcrum about which the valve lifter lever swings is attached to a removable cover plate. When this plate is removed the lifter and follower are withdrawn with it so that a close inspection for wear can be made. The cams are designed to give a lift of 3-8 inch to both the exhaust and inlet valves. The valves are composed of two different kinds of steel, according to the latest practice in valve-making; the heads are of nickel steel and the stems are of carbon steel. The camshaft is a drop forging and is supported by three plain bearings; it is driven off the crankshaft by means of the half-time gearing, which is located in a casing situated at the front end of the motor.

The pistons are long and are equipped with five rings, four being above the wrist-pin and one at the same level as the center of the wrist-pin. There are three grooves in the piston below the wrist-pin, which pick up the oil that is thrown from the crankcase and distribute it to the cylinder wall. The wrist-pin is hollow and is supported by a bushing which is cast integrally with the piston. The connecting rod is attached solidly to the wrist-pin, which oscillates with the motion of the connecting rod and hence uses the bushing as a bearing surface. At the wrist-pin ends the connecting rods are fastened with clamp bolts, which are held in place and locked with washers and lock nuts.

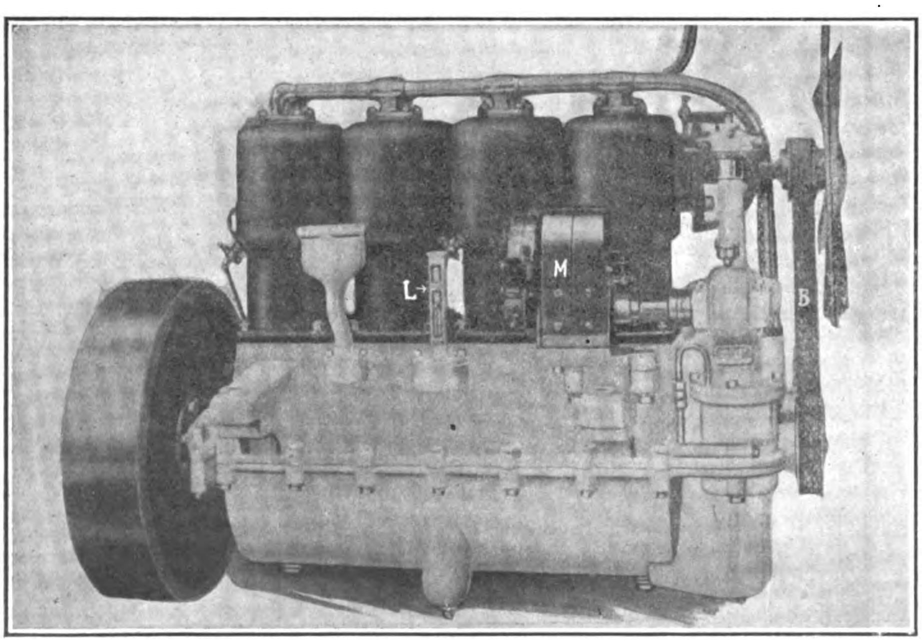

Fig. 2—Magneto side of Model R A Rutenber motor used in larger Lexington cars

The crankcase of this motor is cast in two entirely separate parts. The upper part carries the supporting arms for the motor, of which there are four, and also supports the five bridges which carry the main bearings. The lower parts of the bridges are removable, while the upper halves are integrally connected to the upper part of the crankcase casting. In the four front main bearings there are two supporting bolts, while in the rear main bearing four bolts are provided to give ample protection against the vibration which may be caused by the flywheel. The lower part of the crankcase is not only free from the upper part, but is independent of all the bearings and gearing; hence it may be removed at pleasure without any fear of disturbing any of the moving parts of the motor. It is attached to the upper part of the crankcase by means of bolts, and when dropped, gives easy access to all the connecting rod and main bearings.

The manifolds are placed on the left side of the motor, one above the other. The lower of the two is the intake manifold. The carbureter is suspended from the center of the intake manifold, N, which is of Y-shape and flanged for the purpose of holding the carbureter, which is of the Schebler type. The flange which supports the carbureter is of large size in order to safeguard against a leak at this point.

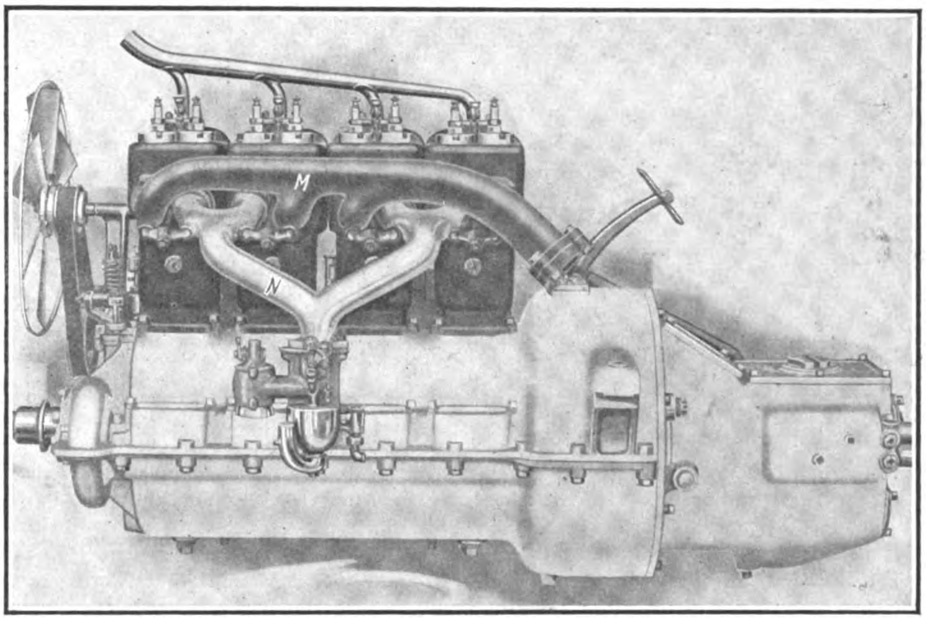

Fig. 3—Manifold side of the Model X Rutenber motor, used in the smaller Lexington cars

The motor is cooled by water, the jacket space surrounding the valve chambers as well as the combustion space. The water circulation is maintained by a centrifugal type of pump, which is driven by gearing and by the same shaft that operates the magneto. The radiator is kept cool by a five-bladed fan which is driven off the end of the shaft by means of a belt and pulley. The bracket which holds the fan is adjustable.

The lubrication is a combination of the force-feed and splash systems. The oil reservoir is located in the lower part of the base casting, being contained beneath a horizontal partition which subdivides the base into an upper and lower compartment. The lower part furnishes the reservoir, while the upper part is a sort of tray carrying the splash troughs which are a factor in the lubrication system of the motor. The capacity of the reservoir is in the neighborhood of two gallons. A gear pump located at the front end of the motor in the bottom of the base chamber draws the oil from the crankcase through a wire-gauze screen and forces it through leads into the main bearings of the crankshaft. After the oil has passed through the main bearings it will overflow into the splash troughs on either side, and create a pool of oil in each of these troughs. At each revolution the ends of the connecting rods are dipped into these splash pools, creating a mist of oil which fills the crankcase and lubricates all the other bearings. The constant level is maintained in the splash troughs because the oil is supplied much more rapidly than it is used, and there is an overflow port provided so that when the oil rises to a certain height it will return to the reservoir. A float level gauge is fitted on the base.

The clutch is of the leather-faced cone type. It is made of aluminum and is recessed below the leather to accommodate 12 springs (M, Fig. 6) so inserted as to provide for easy engagement. The pedal which controls the clutch is adjustable for length to suit the requirements of the driver. The crankcase casting is carried back far enough to enclose the clutch; the gearset housing is then bolted on the end of the clutch casing, making a complete covering for both these parts. The combined housing for these two parts is illustrated in Fig. 6. An inspection cover C, held by the thumb nuts N, is fitted so that easy access may be had to the working parts. A plug L is provided for the insertion of grease into the gearset housing and the casing itself may be taken off by the removal of the bolts B which hold it in place. The gearset housing may be drained by means of a small drain plug located in the bottom of the housing at the front end. The male member of the clutch is

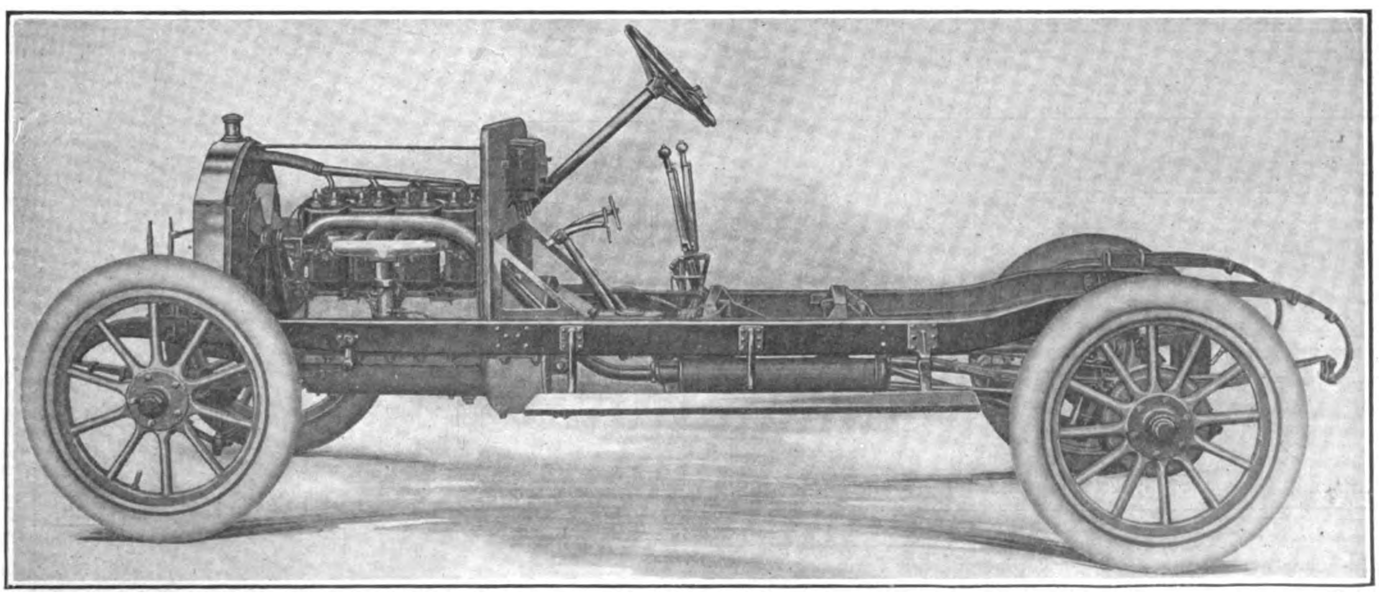

Fig. 4—Illustrating the chassis used in connection with Models D F and E Lexington touring car and roadster

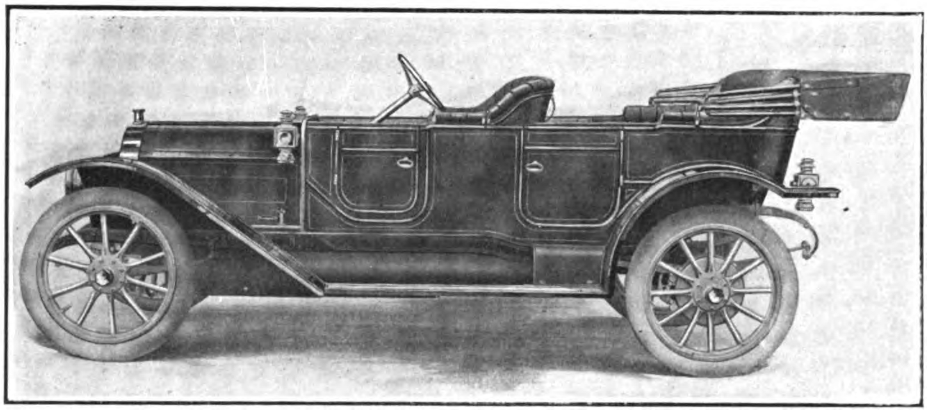

Fig. 5—Model F Lexington demi-tonneau, equipped with Model R. A. motor

held to the drive shaft by a fitting which passes over the squared end of the shaft and is bolted to the clutch by means of the bolts P. The drive shaft D, passes through a stuffing-box at the front end of the gearset housing and engages with the change-speed shaft E. By shifting the shaft E with the change-speed lever, three forward and one reverse speeds are obtained. The shafts are provided with ball bearings and there is a thrust bearing arranged to take the thrust from the clutch.

The drive is taken up beyond the gearset by the propeller shaft, which is fitted with a universal joint at either end, and thence passes through a stuffing box and roller bearing support into the differential. The differential is of the Timken type, a short shaft passing through two Timken roller bearings and terminating with a pinion which engages with the differential, this being also mounted on roller bearings. The rear half of the differential casing is removable by unscrewing the bolts which hold it in place. The bolts are kept tight by the use of split washers which are fitted both on the exterior and interior of the pressed steel housing. A plug for the purpose of inserting lubricating material and a drain are also provided. A flange to which the two triangular spring-mounted torque rods are fitted by means of bolts, is provided on the exterior of the differential housing.

The brakes are of the external and internal type, being mounted on a steel drum as shown in Fig. 8. The internal brakes are operated by the brake lever and form the means of braking the car in an emergency. The illustration shows the method of adjusting for wear and for drag. When the brake is applied the internal lever is drawn back and the two cams P, which are pivoted at P_1, are pushed together, thus applying the brakes. The spring shown in the illustration is fitted for the purpose of drawing back the brakes into their regular position when the lever is released. When the ordinary or foot brake is applied the exterior contracting band is drawn over the drum by means of the bell crank lever and is released by the spring when the pedal is allowed to return to its ordinary position. The drum is held in place by through bolts which are fitted with cotter pins to keep them in position.

The front axle is of the Timken type and is a solid I-beam section, drop-forged. The steering spindles are of alloy steel, heat treated. The rear axle is also a Timken product, being of the floating type revolving on roller bearings. It is enclosed in a housing of pressed steel and is of heat-treated alloy steel. the driving axles are squared at both the differential and wheel ends so that they may be easily withdrawn by removing the hub cap. When this hub cap is removed the end of the axle is exposed, and by inserting a special tool the drive shaft may be removed without disturbing any part of the wheel. The drive is transmitted to the wheels from the axle by means of steel fittings which pass over the end of the squared drive shafts and extend to the wheel flanges. The six bolts which connect the axles to the wheel pass through the brake drums, thus forming a very rigid and efficient connection. Just inside the roller bearings a bushing prevents the passage of oil into the brake drums.

The wheels are intended for 34 x 4-inch tires all around on the D F and E models. They are fitted with universal Q. D. rims and work on Timken bearings, both front and rear.

The chassis frame is of channel section throughout. It runs back on a straight line until it reaches a point about 2 feet forward of the rear axle, where there is a rise which terminates over the rear supports.

The bodies supplied with this chassis are of two types—the Model D F, a five-passenger touring car, and the Model E roadster. They are both supported on semi-elliptic springs at the front with a 2-inch offset center and at the rear with three-quarter elliptic springs with a 2-inch offset. All the springs are steel bushed, reamed to size and fitted with grease cups. They are held in position with clips and tie plates. Both types of body are equipped with the worm and gear type steering gear. The steering column is fitted with an 18-inch hand wheel with aluminum center. The spark and throttle control quadrants and levers are located on the top of the steering wheel.

The equipment consists of a Bosch magneto, five lamps, pump, jack, tools, robe-rail, foot rest and generator. The color of the car and the upholstering are optional. The entire vehicle fully equipped without passengers weighs about 2,700 pounds.

Mechanical Details of Model F Chassis

The Model R A motor, which features the larger chassis, which is used in connection with the Model F bodies and the Lexington coupé, is also a Rutenber product. The bore is 4 1-2 inches and the stroke 5 inches. There are four separately-cast cylinders, as in the Model X motor. The inlet and exhaust valves are located on the same side of the motor and are operated off the same camshaft. The valve springs are on the exterior of the motor and are accessible to inspection and adjustment without the removal of any other parts. There are two nuts on the lower end of the exposed part of the stems by means of which the adjustment of the valves can be easily effected.

The cam action is made accessible by means of removable cover plates which are held in place by bolts. The camshaft is supported at three points in its length, the central point of suspension being in the same transverse plane as the central main bearing of the crankshaft. There are four cams on either side of this central support, which take care of the valve action of all the cylinders. The lower ends of the valve stems are equipped with followers, which rest upon the lifter fingers. The

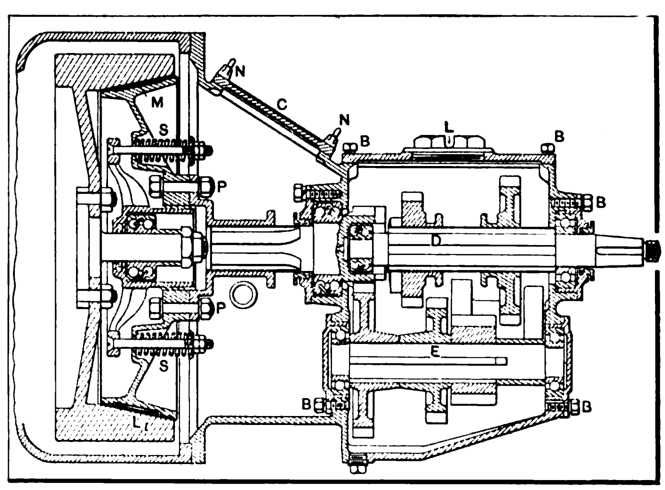

Fig. 6—Vertical section through the clutch and gearset

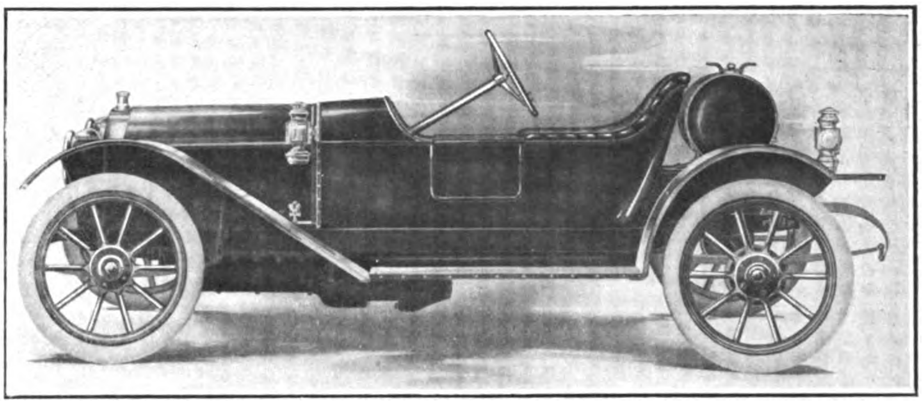

Fig. 7—Lexington Model E roadster, with tank mounted on the afterdeck

action of the cam is transmitted to this finger by means of a roller follower, which gives a lift of 3-8 inch to the valves. The valve-heads are of nickel and the stems of carbon steel.

The pistons are equipped with five rings in the same manner as the Model X motor. The connecting rods are clamped to the wrist-pins rigidly, and the bearing surface for the wrist-pin is provided by a bushing which is an integral part of the piston.

Carburetion is effected by means of a Schebler carbureter which is supported in the same manner as on the Model X motor.

The motor is lubricated by the splash system as well as by the oil which is forced to the main bearing by means of a gear-driven pump located in the front lower end of the base casting. This pump is surrounded by a screen, through which all the oil which is sucked up by the pump must pass. After being led to the main bearings the oil overflows into splash troughs and then passes back into the reservoir, which is located in the lower half of the base chamber. The crank bearings, camshaft bearings and all other moving parts receive their lubrication from the oil which is thrown up by the splash of the connecting rod into the pools of oil contained in the splash troughs. There are two independent methods of draining the crankcase. The upper part of the base chamber which contains the splash troughs is drained by one set of plugs, while the lower half or oil reservoir may be drained by another. The reservoir is fitted with a level gauge L, Fig. 2.

Ignition is affected by two systems which are entirely independent of each other, having separate spark plugs. There are hence two spark plugs in each cylinder. One system is operated by dry batteries and coil, while the other is taken care of by a Bosch magneto M. The coil for the dry batteries is located on the dash and is of the four-unit type. The magneto is located on the opposite side of the motor from the intake and exhaust manifolds and is driven off the same shaft as the centrifugal water pump.

The motor is cooled in the same manner as the model X, the fan driven by the belt B being made larger.

The flywheel is not encased in this motor, the crankcasing terminating at the end of the crankshaft.

The clutch is of the leather-faced cone type, the metallic parts being identical with those used in connection with the smaller chassis. The clutch is controlled by adjustable pedal.

The gearset is of the type manufactured by the T. W. Warner Manufacturing Company. It is of the selective sliding gear type mounted on annular bearings supported by a sub-frame.

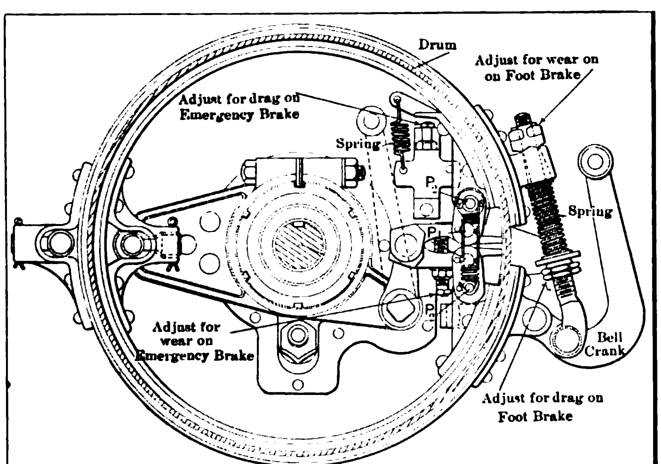

Fig. 8—Longitudinal section through the brake, showing methods of adjustment

The propeller shaft is fitted with two universal joints in the same manner as that used with the Model X motor. Between the clutch and gearset there are also double universal joints so that all strains will be released. The torsional strains are taken care of by triangular torque members of tubular form. The front ends of the torque members are cushioned on heavy springs which are mounted on the cross member of the main frame, the rear ends being bolted to the differential housing.

The front and rear axles are both of Timken manufacture of the same general style as those described for the other type of chassis, but made heavier to sustain the added weight of the heavier motor and body. The other frame members are similar to those of the other chassis except that they are of double dropped construction and somewhat heavier.

The brakes are of the internal and external type, with drums which are 14 inches in diameter and 2 1-2 inches in width. They are bolted to the rear wheels and are adjustable for wear and play.

The bodies fitted with this chassis are of four varieties: two five-passenger touring, one with fore-doors and the other without: a demi-tonneau, and a coupé. They are all mounted in a similar manner with semi-elliptic springs with a 2-inch offset in front and in the rear with three-quarter elliptic springs having the same offset. All the spring eyes are fitted with hardened steel bushings and the bolts are hardened and ground. They are fitted with integral grease cups.

The steering gear is of the worm and gear type of the same general description as that fitted on the smaller cars.

The equipment consists of a Bosch magneto, horn, five lamps, pump, jack, tools, generator, 36 x 4 tires, robe rail, foot rest, and cocoa mat in tonneau. The color of the body is optional, as is also the upholstery.

In placing these two styles of chassis with the six types of body upon the market the Lexington company has not made any radical changes from the models presented in the season of 1911. There are a number of small refinements which have been incorporated in the new models, however, to bring them up to date. Either of the three touring cars is designed to fill the requirements of an every-day car for all-around use. The five-passenger touring cars furnished with the larger chassis are identical except that one is equipped with fore-doors while the other is not. The five-passenger touring car body fitted to the smaller chassis is equipped with fore-doors and is of the same general type as the larger cars except that it is smaller. The coupé, which is fitted on the larger chassis, is furnished with an extra folding seat placed to the left of the steering column so that an additional passenger may be accommodated. The demi-tonneau car is designed for five passengers and is supplied with the larger chassis. The principal differences between this car and the larger touring cars are the closer lines and the longer steering column, which is raked at a sharper angle. The remaining car, the roadster, is mounted on the smaller chassis and has been designed with the object of providing a racy appearance.

Utilizing the Space

AMONG the things that contribute to the pleasure of automobiling and that save wear and tear on the nervous system at a ratio that it is impossible to estimate, are the little things that keep within easy reach the tools and parts needed to make repairs, insure accessibility of the side curtains, etc. Extra cushions or pillows in the car, that can be used as foot rests or that can be utilized to bolster up the back, are another useful addition. More of these simple and useful things are to be found on the new models than ever before; the number is bound to be augmented, too, because the number of car users is increasing, and that means that more people will be interested in the weeding out of the makeshift system that so frequently obtains.

It is usually the novice who institutes reforms; the man who really knows succumbs to the prevailing conditions, whereas the new-comer protests vigorously at the sight that is presented when the occupants of the car are made to file out and stand on the road while the box under the rear seat is ransacked for inner tubes, side curtains, the jack or pump, or any old thing that does not happen to be provided with a home in some other part of the car or in the tool box on the running-board. Then, too, it may be raining at the time and this will add to the varieties of the sensations that are experienced.

Fortunately the refining process is making headway rapidly, and car-users with good common sense are beginning to have the old adage of "a place for everything and everything in its place" apply to the interior of a car as well as to any other piece of property that they may possess. The competition in making sales at the present day is developing this faculty of making things look shipshape; features that are commendable are being generally adopted and those that are the reverse are being eliminated.

Among the articles that are indispensable are inner tubes, and when it is considered that these are so delicate that they should be protected from contact with most other articles carried, and that they may be needed at any moment, does it not seem reasonable that a safe, dry and separate pocket should be provided, one that will be easily accessible without disturbing the occupants of the tonneau? Figs. 1 and 2 illustrate two views of the front seat that show in section on the side elevation such a pocket as described above. The plan view shows the two seatings; it is practically an offset seat, the occupant beside the driver being provided with a very deep seat cushion that allows him to sit well back in a comfortable position. Whereas the cushion on the driving side is less in depth, and the back of the seat is apparently provided with thicker upholstery, in reality it covers a pocket, as illustrated on Fig. 1, that provides room for two inner tubes suspended from a wood bar. This bar is removable and is passed through the inner fold of the tube, to remove which it is only necessary to take out the driving cushion and raise the door as illustrated by the dotted line indicating the door when raised. This door, as indicated on Fig. 2, is made the width of the folds in the trimming, and the hinge in the trimming at the top is naturally provided at the place where the points meet and the buttons are placed. The wood door at the

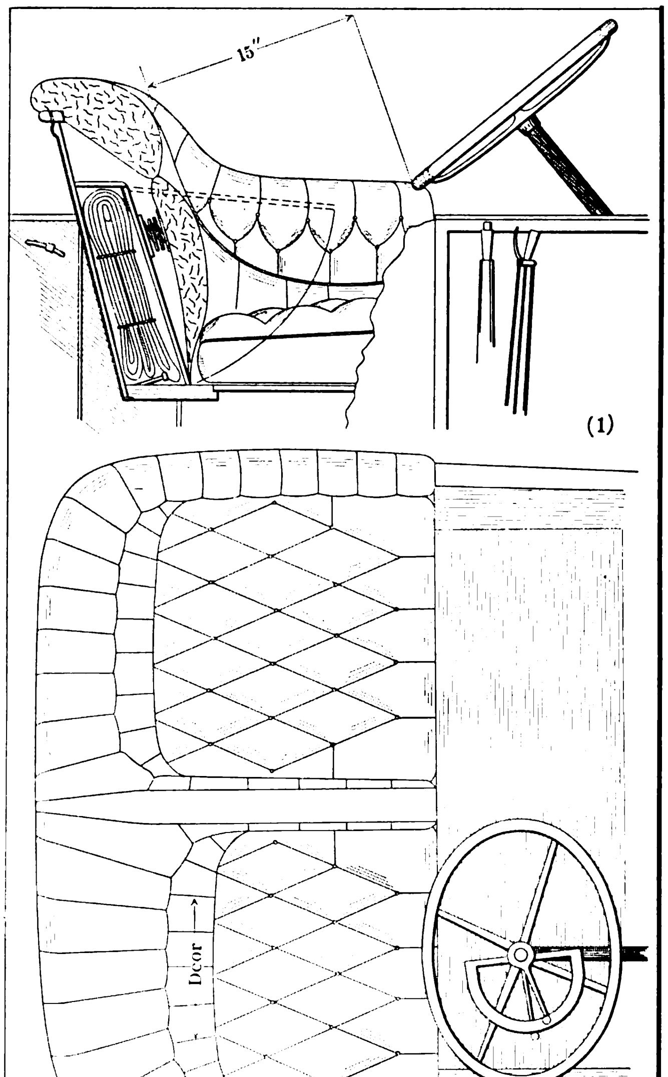

Fig. 1—Vertical section through front seat showing tire space
Fig. 2—Plan of front seats indicating utilization of space

Flaws in Motor Castings

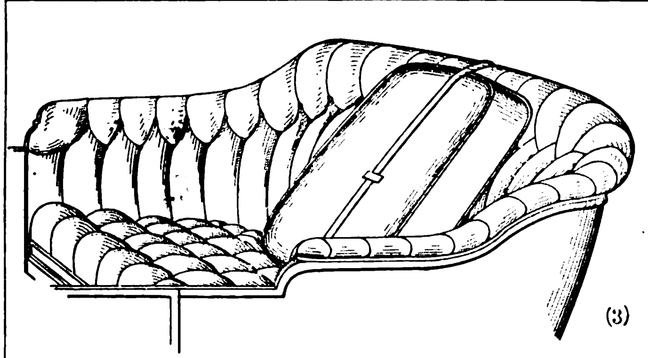
FLAWS in castings are common, and very often impossible to detect. The metal near the top of the mould when making a casting will often be of a quality which is not nearly so desirable as that at the lower part. For this reason cylinders are cast upside down so that the better material will be found in the combustion chamber and heads. In best practice cylinders are cast in moulds which are too long for the particular piece of work in hand; the upper metal is then removed so that the entire cylinder is composed of the best material possible. This practice is common in the manufacture of all automobile engine cylinders where high-grade workmanship is made an objective point. Drop forgings are as a rule more reliable than castings, not being so subject to flaws and blow-holes, and in smaller parts they are used to a large degree. Defects in machined or cast parts cannot be charged to a lack of vigilance on the part of the proprietor of the car, and are mentioned merely to show in what manner breakages may occur which will fall outside of the home care of the car and inside the realm of the maker's guarantee.

CRYSTALLIZED alumina in aluminum bronzes is not only weakening but, being identical with emery, if it is found in a bearing it is as fatal as emery ingrained in the bronze would be. The presence of alumina is easily told, however. It is only necessary to polish a piece of the bronze. If the polished surface is entirely unbroken and smooth, alumina is not present. Should it be there, the buffer wheel produces characteristic streaks and lines.—Durville in *La Technique Moderne* on High Resistance Bronzes.

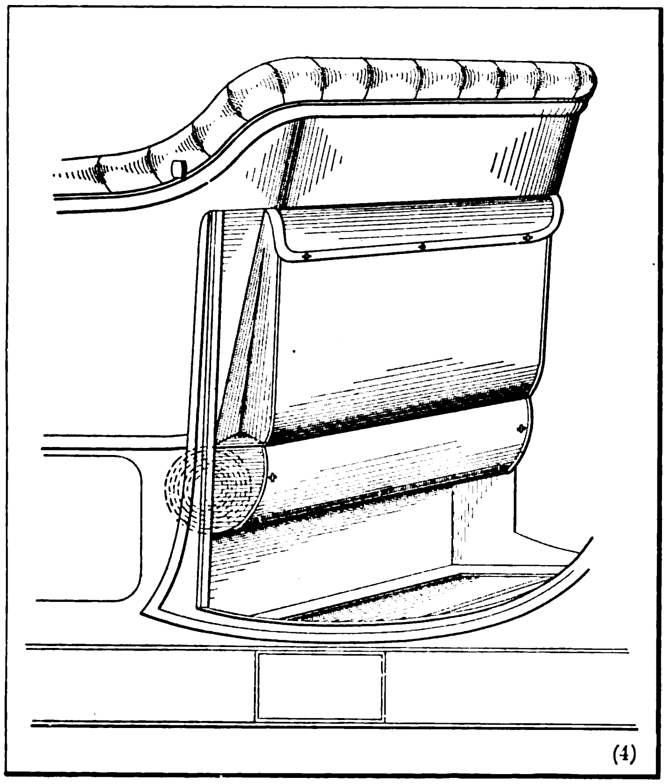
in Car Body Design

back of the trimming is provided with a hinge at the top, and when down its weight and the cushion pressed against it, keep it in its position. As shown, the tubes are in a box formed by the back of the seat, the bottom of the seat frame, the sides that form a rest for the door, and the top piece to which the door is hinged.

Fig. 3 is an improvement that is finding much favor among the users of cars in England; it is simply a leather cushion or pillow, made without springs and very flexible. It is kept in position on the rear seat by means of a strap as shown, and can be removed and placed at the rear of the front seat or it can be used for a foot cushion if desired. If the seat is too narrow for three persons—and most cars are—the third occupant will sit forward and by leaning back on the pillow will have a comfortable seat. The maximum seating capacity will thus have been obtained without crowding. If the occupants of the seat are strangers, the unpleasantness of wedging in shoulder to shoulder is avoided. If the seat is occupied by two persons only, the pillow serves as an arm rest and helps each occupant to retain his position, giving a pleasing individual effect to the widest seat in the car.



(3)



(4)

Fig. 3—Transportable leather cushion strapped to body of car
Fig. 4—How tools can be stored under floor to advantage

Fig. 4 is an illustration showing the storm curtains stowed away in a pocket underneath the front seat at the rear. This receptacle is cylindrical-shaped and is formed of metal. The side toward the rear of the body is open to allow of removing and putting away the curtains, and this opening is covered with a leather flap that is buttoned along the bottom edge and on the sides. This idea of providing a place for the curtains is already incorporated in the new Thomas model, and Fig. 4 shows an adaptation of it, but made to suit the average car with the gasoline tank under the seat. The space from the back of the gasoline tank to the back panel of the seat is usually too small to allow of placing a cylindrical roll large enough to hold the curtains of the average top without showing conspicuously in the tonneau, and to overcome this a leather pocket of generous proportions is provided that will naturally project out from the seat back not less than 5 inches. The cylindrical metal box is fastened to the under side of the seat frame and the flap that covers the opening is made a continuation of the leather pocket, thus balancing up the interior finish of the tonneau and providing room for a receptacle that will contain all the top curtains. These will be carried rolled up loosely and in addition will always be accessible when needed, without disturbing any of the passengers. The roll of curtains is shown in the illustration in dotted lines and the flap is buttoned fast. The pocket shown need not interfere with a robe rail; that can be fastened above it.

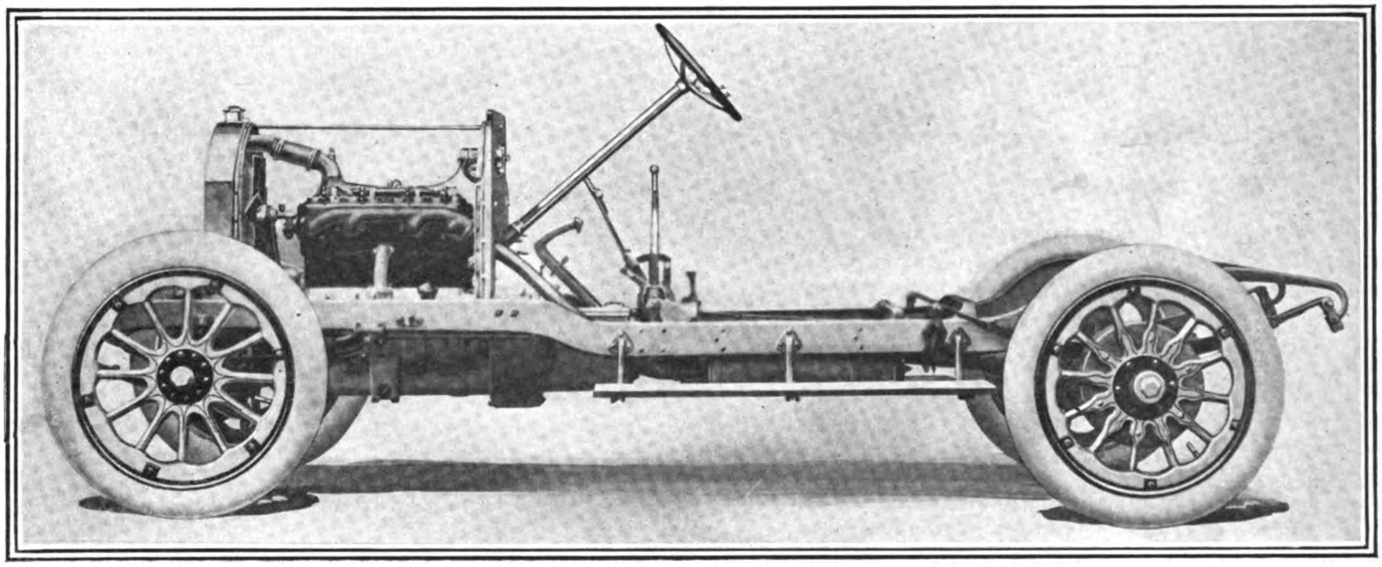
At the bottom of Fig. 4 is shown a door in the floor that covers a box the depth of the frame as indicated by lines on the side. This box is intended to be used to carry the pump, the jack and the heavier articles that are frequently needed, and it suggests the great number of carrying spaces around the car that are not utilized—places that are easily accessible and that can be made to do service in storing away tools and articles needed for touring, and which could be made to supersede the boxes that are carried so conspicuously on the running-board.

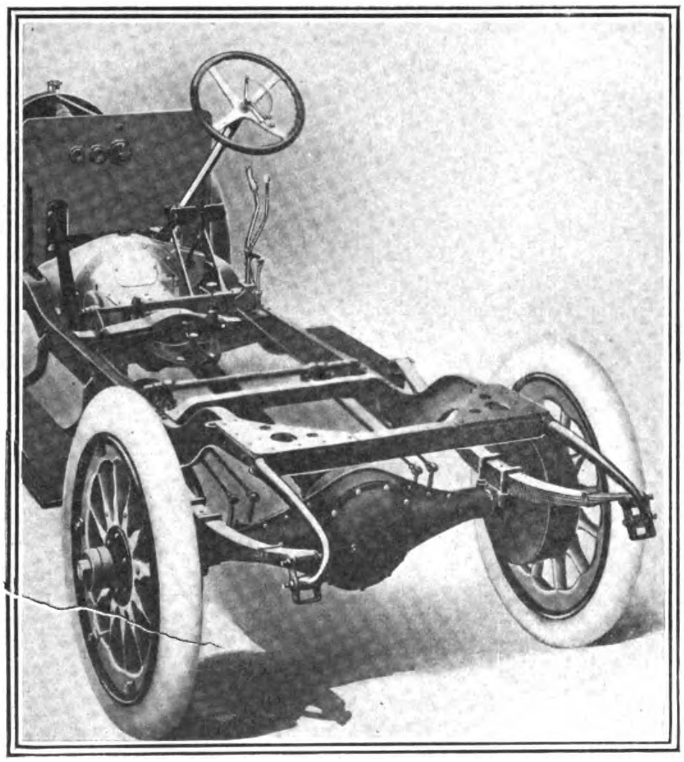
Oil-Burning Motor

DIESEL motors, while in principle too heavy for portable or automobile uses, are gaining new markets as power sources for factories and ships. They are now made not only in the four-cycle but also in the two-cycle type, and their economy no longer depends upon the price of crude oil in the locality where they are set up, as an improvement of the fuel mixer has adapted them to operate with oil of coal tar.

The gas and electric light company of Calais, France, which normally operates with the exhaust waste gases from a steel plant, has installed a four-cycle Diesel motor of 540 horsepower for reserve and emergency purposes, and this operates with oil of coal tar, making the cost per horsepower-hour 1.8 centimes at full power and 2.12 centimes at half power, as the oil costs only 8 francs per 100 kilograms and the average fuel consumption is about 225 grammes per horsepower-hour.

WHAT IS A HOLE IN THE AIR?—"Holes in the air," of which aviators complain, have been rationally explained. If an aeroplane is going against the wind with small speed, relatively to the earth, and then suddenly runs into a current which crosses its path or into a quiet section of the atmosphere, its speed is insufficient to uphold it an it drops and, if the motor power and propulsion are not strong enough to produce a rapid increase of momentum or if the aeroplane is too near the earth, the drop is likely to prove fatal. The explanation accounts for the accidents occurring when the aviator volplanes to earth with the motor power shut off and dives into unexpected currents near the earth's surface caused by hills, trees or buildings.—*Der Motorwagen.*





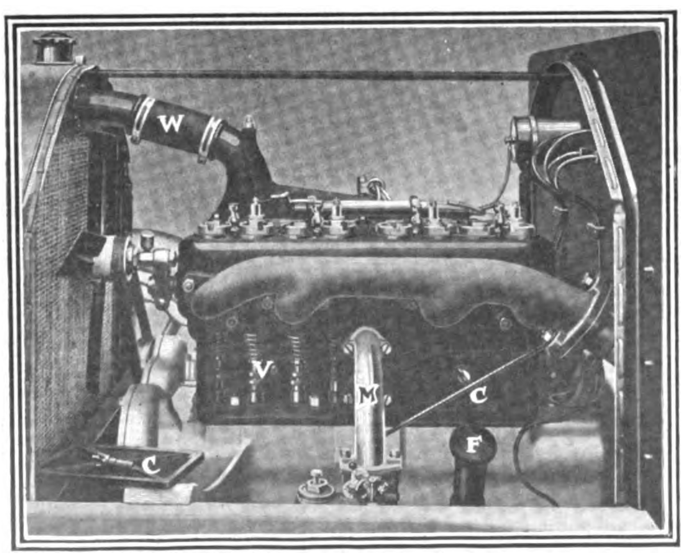


Fig. 1—View of new Pathfinder chassis
Fig. 2—Showing rear axle and suspension
Fig. 3—Illustrating left hand side of motor

1912 Pathfinder

AMONG recent announcements of 1912 models is that of the Motor Car Manufacturing Company, of Indianapolis, Ind., maker of Pathfinder automobiles. This company has placed on the market three body models—a five-passenger touring, a four-passenger phaeton built on toy-tonneau lines and the armored roadster. These are all mounted on the same standard chassis.

The motor with which this chassis is equipped is of the "bloc" type, having four cylinders with a bore of 4 1-8 and stroke of 5 1-4 inches. The valves are all on one side of the cylinders, with the valve springs and push rods V, Fig. 3, enclosed by the covers C to facilitate inspection and removal of parts. The intake and water outlet manifolds are cast integrally with the cylinders, and the opening which permits of inspection of these has been placed between the cover plates to insure easy access. The push rods are supplied with roller cam followers and give the valves a lift of 5-16 of an inch.

Cooling is accomplished by means of the thermo-syphon system. Two large pipes W; a fan F, Fig. 5, driven by the belt B, and a cellular radiator constitute the system. The motor is supported directly by the main frame at four points and the crankcase is extended rearward so as to entirely enclose the flywheel and act as a support for the gearset. A plate is provided in this housing so that the flywheel may be very easily reached for inspection.

The clutch is of the leather-faced cone type. It is 14 1-2 inches in diameter and has a face 2 5-8 inches wide. Six spring plungers beneath the leather provide an easy engagement. The clutch is held to its work by a 250-pound spring. The power is transmitted by a three-speed selective type of gearset of heat-treated chrome nickel. All shafts are mounted upon annular ball bearings.

The ignition is by means of the Eisemann or Bosch dual systems. For magneto adjustment an arrangement has been devised whereby the rear member of the Oldham coupling, joining the magneto M with its drive shaft, has been enlarged and contains 17 holes, the other member having 16, hence the adjustment may be varied by steps of 1 degree and 18 minutes.

There are two independent systems of oil circulation, each system having its own circulating pump, of the plunger type.

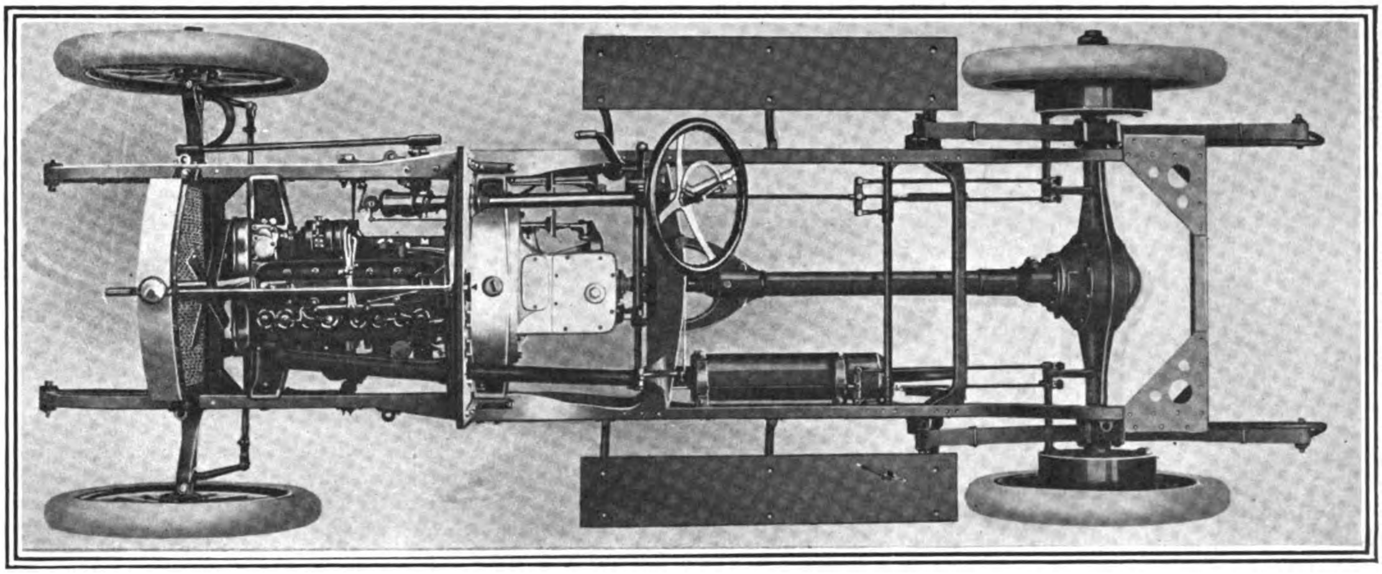

Fig. 4—Plan view of Pathfinder chassis
Fig. 5—Control mechanism of the new car
Fig. 6—Right-hand side of motor, showing magneto

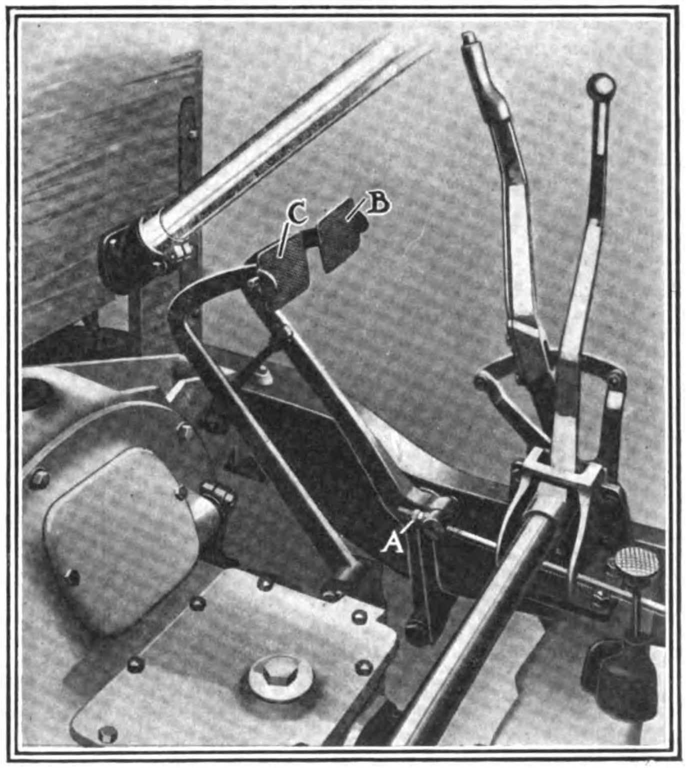
Makes Its Bow

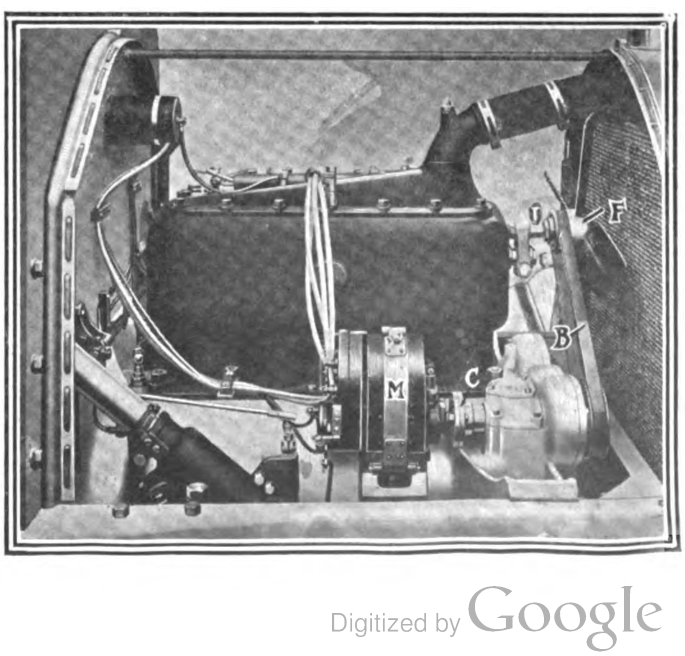
These pumps are located on the valve side of the motor and are driven by the camshaft. Both pumps and their check valves are removable by withdrawing the plugs which are fitted beneath them. The oil is forced from the pumps to the sight feeds on the dash, all the piping except the leads to the sight feeds being incased in the crankcase casting to afford protection and insure a neat appearance. The oil reservoir is in the base and is filled by means of the filler tube F. There are two separate sight feeds located on the dash, one for each system. Both are of the bull's-eye type and are flush with the face of the dash. The oil flows from one sight feed to the rear main bearing and overflows into the rear splash trough and from the other sight feed to the timing gear case, overflowing into the foremost splash trough. In this way the oil supply will be uniform whether the car be ascending or descending a hill.

One universal joint, of the Spicer type, connects the gearset and propeller shaft. The drive shaft is covered by the torque tube. Under full passenger load a straight line drive is obtained, while with an empty car there is a three-degree angle between the shafts. The rear axle is of pressed steel with a vertical weld, its thickness being 3-16 of an inch.

The rear wheels are mounted upon two rows of ball bearings and are driven with six-jawed clutches. Brake drums are mounted on the rear wheels and are bolted to alternate spokes. Inside these drums are a pair of internal expanding brakes mounted side by side. They are 16 inches in diameter by 1 3-4 inches in width and are operated by means of whiffletree equalizers mounted on one of the frame cross members. Each brake can be adjusted from a point conveniently located under the floor boards at A, Fig. 5.

Both front and rear wheels have 1 5-8-inch spokes and carry Universal demountable rims, of which the equipment specifies one extra. The tire equipment is 34 x 4 inches all around, the tread being 56 inches, although a 60-inch tread will be supplied to Southern customers if so desired. The suspension both front and rear is by means of semi-elliptic springs. In front the length is 38 inches and in the rear 50 inches. The center of gravity of the car is kept low by means of the flat springs and a dropped frame. The shackle pins are hardened and lubricated by grease cups.





The change speed and emergency brakes are at the side and within both the body and the frame. Spark and throttle levers are placed as usual upon the 18-inch corrugated mahogany hand wheel. Clutch and brake pedals, C and B, are placed on the footboard, with the accelerator between the two. The clutch and brake pedals have separate fulcrums. The centers are so arranged that the difference in arcs through which each pedal will travel is very slight. The object of this construction is to give straight-line pull upon the brake linkages and at the same time to obtain the proper reduction at the brake rocker arm.

In the steering gear a full worm wheel is used so that should there be wear the wheel may be rotated and a fresh surface engaged with the worm. As the worm is set upon a square shaft it can be so turned as to present four new wearing surfaces. The steering gear may be set at any angle without interfering with the adjustment.

The armored roadster body is of distinctive design. On this car the tank is carried in a portion of the body back of the seats. The rear is bevelled off in order to accommodate spare tires. Fore-doors, steering wheel and control levers on the right side and ventilated dash are features of the design. On the runabout access may be had to the seats from either side.

The frame is of channel section, being 4 1-2 inches in height throughout the major part of the side members. The thickness of the metal is 3-16 of an inch and the flanges vary from 2 to 5 inches in width, depending upon their location. At the front the frame is 30 inches wide, while at the dash it widens out until it is 34 inches. The frame is dropped 3 inches just back of the dash and 6 1-2 inches at the rear. There are four transverse members to the frame, one being just back of the gearset. This is a malleable iron casting and serves to stiffen the frame and help support the gearset, the torque rod support, the muffler cut-out and the emergency brake rod.

New Electric Limousine

A FIVE-PASSENGER limousine driven by electricity is now offered for sale by the Waverley Company, of Indianapolis. The most modern of electric equipment was necessary to operate a body of these dimensions and yet maintain the requisite speed and mileage capacity. The wheelbase is 104 inches, body sill 129 inches and length over all 144 inches. The wheels are larger than the former electrics produced by this company, the tires being 34 x 4-inch rear and 34 x 3½-inch front.

The motor is of the Waverley multi-polar type with an overload capacity of 360 per cent., which transmits its power to the transverse shaft by means of a silent flexible gear. From the transverse shaft the power is transmitted to the floating rear axle by a shaft drive and herringbone gears. All running parts work in a constant oil bath. Battery and arc are completely controlled by the Waverley No-Arc controller, which provides four speeds either in a forward or reverse direction. The motor cannot be started, however, on any other than the low speed, thus making for the safety and comfort of the driver and passengers.

Pains have been taken by the makers to have the upholstering as luxurious as possible and to give the car a tasteful design The general effect is that of the French town chariot.

What Causes Sweating?

SWEATING is caused when the gasoline is vaporized, due to refrigerating effect. Every liquid, when it is changed from its liquid state to a gas form, absorbs heat from its surroundings and the temperature of the surroundings is lowered. The amount of this refrigerating effect depends upon the characteristics of the liquid employed. Gasoline, for illustration, does not refrigerate nearly as much as anhydrous ammonia. The mere fact that the carbureter exterior and perhaps the intake manifold frosts up is a sign that a considerable amount of gasoline is being vaporized, perhaps too much. It might be well to readjust the carbureter with a view to starving the mixture with the hope perhaps that there will be less frosting and that the mixture will prove to be more efficiacious for its purpose. The fact that there is no frosting must not be taken as an absolute sign of good working conditions, because if the liquid goes into the combustion chamber before it vaporizes it will then "crack," forming a carbon deposit over the internal surfaces.

Loss of power is due to so many things that it will be impossible to put your finger upon the precise trouble without going to some pains, more or less systematically. It is to be hoped that the compression in your cylinders is good, that the carburetion is satisfactory, and that the ignition system is capable and well timed. With all these matters properly attended to, it remains for your air-cooled motor to work at a sufficiently low temperature to permit of a sufficient weight of mixture to enter the cylinders and perform useful work. If your trouble is due to overheating, loss of power may then be charged to one or more wrong conditions, as pistons that stick when they are heated, due to expansion, poor lubrication, due to the burning up of the lubricating oil, and insufficient mixture, due to the fact that the incoming mixture is rarefied by heat, and this condition may be accentuated sufficiently to result in a noticeable loss of power.

THREE YEARS AHEAD OF US.—"Of course," says *The Automobile Engineer* for September, speaking of American manufacture, "the adoption of the long strokes will act just as it has here (in Great Britain), by producing lubrication, vibration and noise troubles; so it is likely to be three years before the average American engine is as good as is the average European engine now."

My 1912 Automobile

Some Conceptions of What the Ideal Car Should Be

Wants Multiple Disk Clutch

Editor The Automobile:

Permit me to add my idea to the many for an ideal 1912 motor car: The power plant of the car should be composed of a four-cylinder, four-cycle engine of 4 1-2-inch bore and 5 1-2-inch stroke, which would give the car about 32.4 horsepower, which is sufficient for touring purposes. The four-cylinder car is, I grant, inferior to the six-cylinder motor, but for horsepowers under forty I cannot find enough advantage in the six to warrant the extra cost. The engine should be of the L-head type, which will hold down the cost of construction, and the cylinders cast in pairs. The motor should be equipped with a Schebler or Stromberg carbureter and a four-cylinder tire pump fitted with clutch for engagement for pumping up tires.

Ignition should be from a Remy magneto light, which will furnish a complete electric lighting outfit for all lights on the car and also a dual ignition system.

A multiple-disk clutch of ample size and strength equipped with a ball bearing to act as a thrust bearing for same. Drive should be by shaft, enclosed and running on roller bearings with one universal joint, three-speed and reverse selective transmission running on roller bearings should be incorporated in rear-axle assembly. Rear axle should be of full floating type.

All wheels should be on roller bearings and the springs suspension should be of the best trade, being half ellipitic in front and platform in rear; 36-inch x 4 1-2-inch tires all around, and standard quick-detachable rims used, not demountable. The wheelbase should be 120 inches. The front axle should be of vanadium steel in I beam.

A 25-gallon gasoline tank should occupy the rear of the chassis. The gasoline from this tank should be forced by automatic pressure to a small tank on the dash, and from thence flow by gravity to the carbureter.

The bearings in the motor should be of best babbitt and of large size the crankshaft main bearings not being less than 3 inches in length.

Lubrication should be from a self-contained plash in the crank case. Oil circulated by a gear pump with a glass sight feed showing amount of oil.

Frame should be best pressed steel, narrowed in front to permit short turns.

The brakes should consist of a service brake by pedal, operating two external contracting bands on drums on rear wheels, and the emergency brake operated by lever should operate two internal expanding bands on the same drums. All brakes should have easy adjustments and equalizers. The control of the car should be from the right side in every sense of the word; no control levers in the center of the car.

This car should be equipped with a five-passenger touring car body with detachable foredoors, and ventilators in dash of a serviceable size. The equipment should consist of a good speedometer and clock, foot rest in tonneau and robe rail, good top and side curtains, a glass windshield, electric lights all around, tire carrying-irons at rear of car, a good bulb horn, and full set of tools, etc.

The above car should weigh 3,000 pounds and cost $2,000, and should be put on the market by some old-established and reliable concern who have done business in building motor cars for years past. The parts for this car should be sold at a fair price direct from the factory to the user.

Lebanon, Pa. C. L. W.

Specifies Five-Inch Tires

Editor The Automobile:

The following are the specifications of my ideal car:

The engine should have six cylinders of the L type, cast in pairs, with removable plates over water jackets to allow cleaning, having a bore of 5 inches and stroke of 6 inches, with 2 3-4-inch valves with adjustable lifts, valves enclosed to exclude grit, giving it a full 60 horsepower.

Offset crankcase split in half with side opposite camshaft removable to allow access to and the removal of the crankshaft, connecting rods or pistons whenever necessary without having to take down engine.

The lubrication should be by positive force feed by gear-driven pump to all bearings and splash to connecting rods and pistons, oil contained in tank at side of engine with sight feed on dash.

Ignition should be by either Bosch or Eiseman magneto and storage battery, with two sets of spark plugs over valves.

The cooling system should consist of honeycomb radiator with gear-driven fan and water pump.

Selective type of transmission is my choice, with four speeds forward and reverse running on ball bearings with direct drive on third speed and geared 3 1-2 to 1 on direct drive.

The large diameter multiple-disk clutch should be mounted on ball bearings running in oil, with six tension springs equidistance apart, to allow taking up of wear.

A through shaft fitted with two universal joints should be packed in grease to differential with a torsion rod alongside, and from differential to rear wheels through live axle. Both differential and live axle running on Timken roller bearings.

The front axle should be of I-beam pressed steel, and a full floating type rear axle ought to be installed.

Twelve-spoke, 38-inch wheels of wood, mounted on Timken roller bearings should be fitted, these to be shod with 5-inch tires; all wheels with quick detachable demountable rims.

There should be four large brakes on two rear wheels, two internal for emergency, and two external for service.

The wheelbase should be 130 inches.

Semi-elliptical springs should be in front and three-quarter elliptical in rear, with Truffault-Hartford shock absorbers on each spring.

Steering should be by worm and sector gear, irreversible type, with 18-inch wheel.

The equipment should consist of foredoor torpedo type body seating five persons with comfort, with space enough in tonneau to accommodate two auxiliary seats whenever desired, top, windshield, speedometer with clock, two extra rims with tires, covers and tire irons, tire trunk, trunk rack and trunk, foot and robe rails, two headlights, two side lights and one tail lamp, all electric, getting current from storage battery charged by generator driven by engine, electric horn, engine-driven tire pump, jack, complete set of tools, and a positive self-starting outfit. A car such as this should cost $4,000 or thereabouts.

Hazlehurst.

Hazlehurst, Miss.

Cheapness a Factor

Editor The Automobile:

I have followed with great interest the opinions of the various readers of The Automobile as to what the ideal 1912 car should be. I notice that in nearly all cases a high-priced car is specified, as is perhaps perfectly natural when it is considered that the very best materials and construction will enter into a car classed as ideal. It would seem to me, however, that a somewhat cheaper car should be described as the quality of cheapness is a very important factor to the average buyer of an automobile. Interested.

Readville, Mass.

Letters Answered and Discussed

Pipe Joint

EDITOR THE AUTOMOBILE:

[2,851]—Would you kindly tell me of a method of joining together two pipes of different sizes? I wish to make a solid joint that will not be apt to bend at the point of juncture and will hold its shape against considerable strain.

AMATEUR.

Fargo, N. D.

The best method of joining the pipes is by means of a brazed flange, as shown in Figs. 1 and 2. In the sectional view an idea of the way in which the flange is fitted is given. And if the fitting is made in this manner there will be no constriction of the free area. The distance C in the plan view should be equal to the diameter of the pipe plus twice its width in order to give a reliable fitting. The two inner circles in this drawing represent the thickness of the pipe and the outside circle shows the outside of the pipe flange.

Pounds in Neutral

Editor THE AUTOMOBILE:

[2,852]—Kindly let me know through the columns of THE AUTOMOBILE the following: I have a 26-horsepower, four-cylinder, four-cycle motor, which, when in neutral, develops a distinct pound. However, when traveling at speed this noise disappears entirely. I have thoroughly cleaned the cylinders, and the carbureter is positively correct. What is the matter?

A SUBSCRIBER.

New York City.

You probably advance the spark too far when the engine is running free. This will produce a distinct pound. Loose parts would knock while running in gear.

Cylinder Leaks

Editor THE AUTOMOBILE:

[2,853]—I am inclined to believe that there is a leak at some point in one of the cylinders of my four-cylinder 30-horsepower motor. Would you kindly tell me where the usual sources of leaks are found, and if there is a leak how it is detected? I would be greatly obliged for

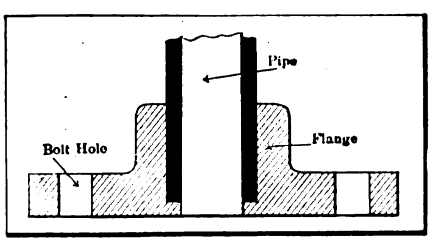

Fig. 1—Section through a pipe to which a brazed flange is fitted

The Editor invites subscribers to communicate their automobile troubles and personal experiences, stating them clearly on one side of the paper. If the nature of the case permits, send a sketch, even if it be rough, in order to assist to a clearer understanding. Each communication will receive attention in the order of its receipt, if the writer's signature and address accompany it as an evidence of good faith. If the writer objects to the publication of his name, he may add a nom de plume.

My Best Repair

Temporary automobile repairs made by the driver or owner while on the road and permanent repairs made in the garage after the run is over, are interesting to all automobile owners.

Every driver at one time or another gets up against it. Something breaks or gets out of order on the road—a stop has to be made and some repair effected.

It may be a spring leaf has broken; a shackle bolt or strap may break; a steering tie rod is bent; the car skids into a curb and bends a steering arm or the starting crank; a throttle or magneto connection breaks owing to vibration; a radiator leak is started by a stone or some other means; a leak in the gasoline tank is discovered; there is a small hole in the gasoline feed line; a brake facing may burn out; a brake connection breaks; a front axle gets slightly sprung; a clutch starts slipping, or any one of a thousand things may happen.

Every automobile owner is interested in knowing how repairs have been made, how long it took to make them, how much they cost, and by whom they were made. All this information broadens the knowledge of the automobile owner and so helps the industry.

Thousands of car owners who are readers of THE AUTOMOBILE, *have had experiences of this nature and have made a temporary roadside repair—a permanent cure at the garage. We want you to write in simple language in a letter what repair of this nature you have had to make, how you made it, how long it took you and how much it cost.*

You can make with your lead pencil one or two rough sketches indicating the broken or damaged part and showing how the repair was made.

We are going to publish these repair letters from week to week in these columns. Every reader should send in one experience or repair and how accomplished.

Some have experiences with short circuits, adjusting carbureters, motor knocks, hard starting, noisy timing gears, etc. Information on how these were discovered or rectified are equally interesting.

The experience of each reader is interesting to every other reader. To you, some of your repairs or experiences may be commonplace, but to owners of automobiles with less experience they are most interesting.

Analyze your past experiences and send in one or two of them.

Give your name and address, legibly written. If you do not want your name to appear, make use of a nom de plume.

Editor THE AUTOMOBILE.

any information that you would give me regarding this trouble.

R. C. HOYT.

Camden, N. J.

First test for leaks about the spark plug or at any other points at which there is an opening into the cylinder. The test is made by putting light grease or heavy lubricating oil about the suspected points and watching for bubbles.

If the leak is in the piston it may be detected by allowing the motor to have a rich mixture and then opening the crankcase to see if there is any smoke within the confines of the casting. If there is smoke it may be taken as a sign that there is such a leak. The piston rings should be examined in a case of this nature.

Should the cylinder be cracked between the combustion chamber and the water

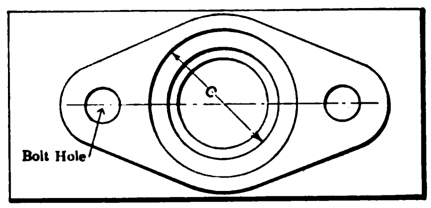

Fig. 2—Plan view of a brazed pipe flange showing the bolt holes

jacket the damage may often be very hard to detect owing to the fact that the crack will remain closed while the motor is cool, but as it heats up the crack will open. A cracked cylinder, though, will make itself apparent by the boiling cooling water.

Outside of the cylinders the valves should be noted to see if they are perfectly clean, as a leak will occur in the compression if there is a flake of carbon between the valve and its seat. Leaky exhaust manifolds are detected by a wheezing sound and leaky intake manifolds by a weak mixture which will cause popping back into the carbureter.

Regarding Carbureters

Editor THE AUTOMOBILE:

[2,854]—Being a subscriber of THE AUTOMOBILE I would like to ask the following questions:

(1) When setting the adjustments on a carbureter, how many parts of air and how many parts of gas should be given?

(2) When setting the float level of a carbureter, when all the gasoline is out, how is it possible to tell when it is at the correct level?

A. J. K.

College Point, N. Y.

(1) In adjusting the carbureter the parts of air to gasoline are not determined, as they are allowed to vary at different speeds of the motor. The maximum explosive effect of gasoline is obtained when there are about eight parts of air to one of gasoline vapor. The carburetion will vary at different motor speeds on account of the greater amount of suction produced by the piston when traveling at the higher speeds and for this reason it is much easier to secure good carburetion at higher piston velocities.

When it is necessary to adjust the carbureter the matter should be gone about systematically and the steps taken well defined or else it will be an impossibility to secure the best results except by accident. The first step is to set the air valve in the mid-position, open the throttle about halfway, retard the timer and start the motor with the gears in neutral or the clutch disengaged. The throttle valve is then opened and closed quickly, with the timer set in different positions and the results noted. If there are back-fires, either open the fuel valve or close the air valve, according to judgment; if in doubt, try both and note which gives the better results. If instead of back-fires the motor smokes, close the fuel valve slightly or open the air valve. When the motor works satisfactorily on different positions of the timer the car should be taken out on the road and put into high speed and the speed acceleration noted with the carbureter setting in the position which seemed best in the above-mentioned adjustments. Change the fuel valve setting without touching the air regulation until the motor picks up best along the road or up a hill, then note the effect of a slight change in the air valve in either direction. Vary these two (fuel and air valves) alternately until the most satisfactory results are obtained.

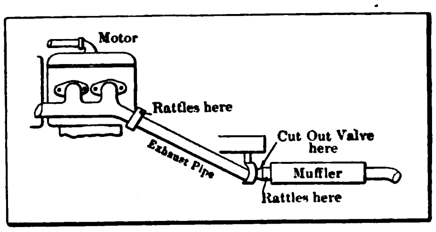

Fig. 3—Illustrating points of leakage in loose exhaust pipe

(2) The different makes of carbureters vary to a great extent in the manner of making the float adjustments. The height at which the float will be carried will vary with the density of the gasoline so that without the fluid in the chamber it would not be very well possible to ascertain the correct height with any degree of accuracy. The gasoline level should be about 3-32 inch below the level of the nozzle. It would be advisable in making the adjustment to obtain directions from the maker regarding the type you employ.

Exhaust Pipe Rattles

Editor THE AUTOMOBILE:

[2,855]—The exhaust pipe on my car has become loose so that it rattles. I think it is probably due to having attached a cut-out valve in the position shown in the accompanying sketch (Fig. 3). It is loose both at the entrance to the exhaust manifold and at the muffler. Is there any way in which it may be tightened?

Ellenville, N. Y. A. D. P.

This is a job which should be turned over to a pipe fitter if satisfactory results are to be obtained. It might be possible to remedy the rattle temporarily by lagging the connections, with asbestos wrapped firmly about the points indicated, fastening this by means of metal strips which have been bent so that a small bolt can be passed through the ends and drawn tight. If necessary, the exhaust pipe should be rethreaded.

Needs More Air

Editor THE AUTOMOBILE:

[2,856]—My motor, which ran very well up to a short time ago, has acquired some faults. The trouble seems to be in the carbureter, as the motor will smoke at all speeds. I do not like to change any adjustments without knowing what I am about. I wish you would direet me.

CARBURETER.

Saginaw, Mich.

You will find elsewhere on this page complete directions for making the adjustments on the carbureter. Before starting to adjust, note if it is clogged in the air passage, as shown in Fig. 4.

Carbonic Gas in Tires

Editor THE AUTOMOBILE:

[2,857]—Some time ago there was an article in THE AUTOMOBILE relating to the effect of carbonic gas on the rubber in tires. My recollection is that it was stated that the gas had no deleterious effects, but that it leaked through the pores of the rubber much quicker than air will. I would thank you very much if you would tell me whether I am right or not concerning the properties of this gas.

J. S. A.

South Orange, N. J.

The properties of this gas in relation to rubber are as you state.

Loose Steering Wheel

Editor THE AUTOMOBILE:

[2,858]—I would like advice on how to tighten my steering wheel. As far as wear is concerned, everything seems to be all right, but as yet I have been unable to find the correct place to make the adjustment. My car has a worm and sector type of steering gear.

J. H. B.

Swedesboro, N. J.

Loosen the nut in the eccentric bushing at the sector. Turn the bushing and tighten the nut. If the play is in the ball thrust bearing, the adjustment is made by tightening the nut provided for the purpose. If the balls are worn they should be immediately replaced.

Washing Radiators

Editor THE AUTOMOBILE:

[2,859]—In your issue of Sept. 14, under the title of "The Upkeep of the Car" you advise washing the radiator of the car with a soda solution. Can you tell me what would be the correct solution to use?

G. F. W.

York, Pa.

The solution need not be carefully measured, a generous handful to a pail of boiling water being sufficient. Clean water should be run through the radiator after having washed it with the soda.

Don't Use It

Editor THE AUTOMOBILE:

[2,860]—Would you kindly tell me what they put into the gasoline to increase the power of a motor when in a hill climb or race?

(2) What is a live rear axle?

READER.

Pittston, Pa.

It is not a very advisable proceeding to put anything into the gasoline. Picric acid has been used to some extent.

(2) A live rear axle is one which turns with the wheels of the car, the power being delivered through them.

Oil in Gasoline

Editor THE AUTOMOBILE:

[2,861]—In regard to the practice of putting oil in the gasoline supply for the purpose of lubricating the cylinders, do you consider this advisable? If not, kindly inform me of the disadvantages incurred.

S. LINDON.

New York City.

This matter has been well threshed out in the columns of this paper in the issues of March 23, page 783; April 13, page 905; April 27, page 1014; May 11, page 1092; June 1, page 1223; June 22, page 1404, and July 20, page 108.

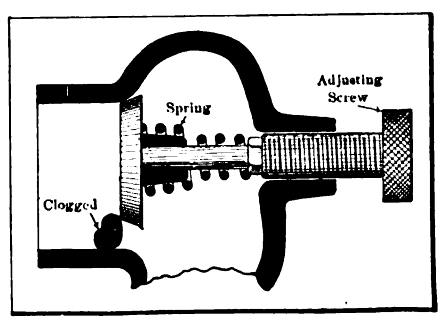

Fig. 4—Point at which the air valve of carbureter may be choked

Finding Weak Spots in the Car

THE weak spots of a car are not always parts that are directly connected to the driving mechanism, but are frequently the little adjuncts which may be considered luxuries, rather than necessities, so far as the actual capacity for travel of the vehicle is concerned. These auxiliary fittings are often of a nature that renders them necessities; but when the more vital parts of the machine are well cared for, it suggests a great lack of thoroughness on the part of the responsible parties if these parts are neglected to such an extent that they do not compare with the other parts of the car in appearance, material or adjustment.

A lack of cleanliness may go a great way toward destroying the efficiency of a given part. Take, for instance, the brakes. It very often happens that oil will leak into the brake bands of a car. This oil will flow from the differentials into the brake drums by means of the rear axle, and will collect there, forming eventually into a thick gum or paste, which gives the brakes a marked tendency to slip. A case where a grease-filled brake drum very curiously brought about its own destruction is illustrated in Fig. 2, where a drum is shown which was broken in a collision. The brakes were jammed on as the emergency of a rapidly approaching car on a narrow turn arose, and, on account of the thick coating of grease with which the brakes were covered, the car swerved and collided with the other vehicle, thus incurring the damage shown.

The mudpan has nothing to do with the running qualities of a car, but if swung too low it may have a very nasty tendency to drag and bump along the road, reducing itself in a very short space of time to a shapeless mass of metal, which will make the most handsome car appear a very slovenly outfit. In Fig. 1 a case is shown where the pan was submitted to the vagaries of a rather irregular highway, and as a result was soon reduced to the state depicted in the illustration. When the pan is fitted it is not with the desire of removing the high spots from a bad road, but as a matter of precaution in the desire to protect the motor from the dirt and dust of the highway. In fitting the pan a little perspicacity should be employed, and where very rough going is to be encountered it should be fitted with due regard for the necessary clearance. In foreign travel, especially in France, where the roads are as a rule very flat, the low clearance allowable very often deceives those who come from abroad to tour in this country, and in many instances the low suspensions of the foreign cars render them unsuitable for transcontinental touring in this country.

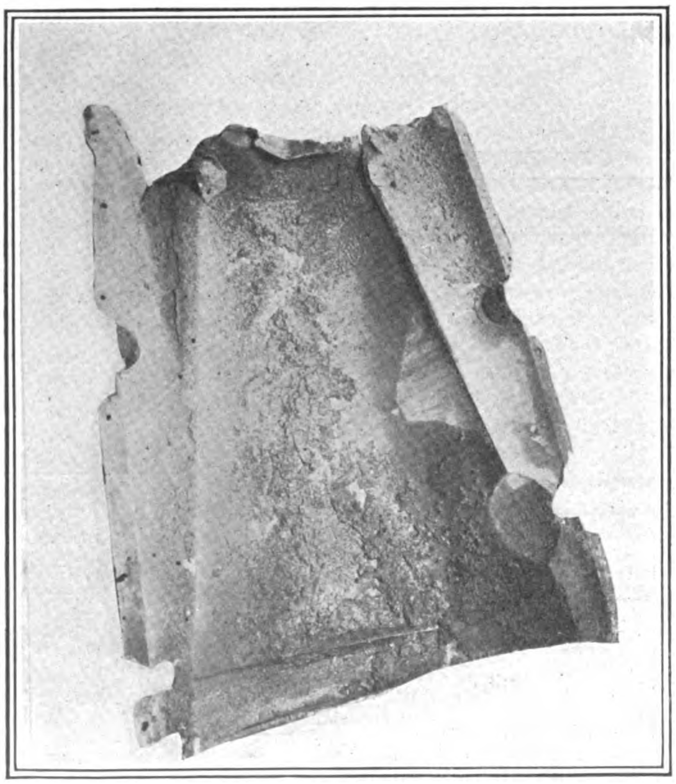

Fig. 1—Battered mudpan which was swung so low that it struck the road

In the case of frame members and springs, which are classified in the mechanics of materials as "simple beams," the greatest stress in the material is at the longitudinal center between supports, and therefore the metal which composes the various leaves of a spring is generally tapered so that it attains its maximum width at this point. In the case of frame members the same may be said to be true, though they are generally made of such sectional strength that a large factor of safety over their probable maximum load is given. It seems strange in the light of these facts that material should be cut away from the vital parts of a spring or other part of the mechanism without some compensating features in the way of added material or other strengthening device. When a spring fails it will be, as a rule, through the center of its length, and the failure will be caused by bending and tension, so that if a hole is drilled through a spring at this point it will be weakened in the very spot where the greatest strength is needed to resist failure. In Fig. 3 a spring is shown which was weakened by drilling a hole through the center. A bad spot in the road was encountered and the spring, as may well have been expected, failed at the point where the hole had been drilled.

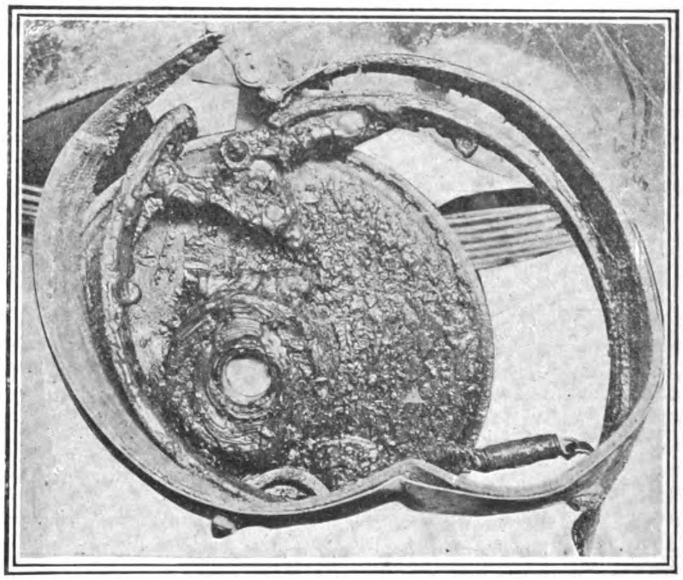

Fig. 2—Broken brake. Note the thick coating of accumulated grease

In order that the best construction be maintained through any piece of mechanism an equality of strength should be maintained. That is, there should be no more weakness in the direction of compression than there is by tension or torsion. In designing the machine these strengths should be equated in order to determine the correct thickness of the material; and in case any holes are to be bored for clips or holding-down bolts the weakening influence of the holes through the material should be included in the calculations. Each leaf of the spring is under both tension and compression when carrying a weight. This may be illustrated by taking for an example a plain plank resting upon two supports, one at either end. If a weight is placed upon the center of the plank it will sag and the upper surface of the plank will be compressed while the lower will be stretched or placed under tension. If this is not clear it may be easily demonstrated by coating the board with some non-elastic material and the effect of bending the plank noted upon the same. The tension and compression in the spring are both at a maximum at the center of the plank, as they would be in the spring, and it can readily be understood that accidents such as that shown in Fig. 3 may be expected where the hole is drilled and no compensating material added to this vital part.

The loose fan bracket is rarely the fault of the builder so much as that of the subsequent proprietor of the car. It will generally manifest itself by a sort of rattling sound which it gives forth as the car is proceeding on its way. If this noise is taken cognizance of at once, the fact that the fan hits the radiator as it revolves will be noticed in time to prevent the demolition of the fan. When the fan is driven by belt the bracket will often work loose after the car has been driven for some time. The result of a loose bracket is shown in Fig. 4, and, as may be seen, the fan is beyond repair.

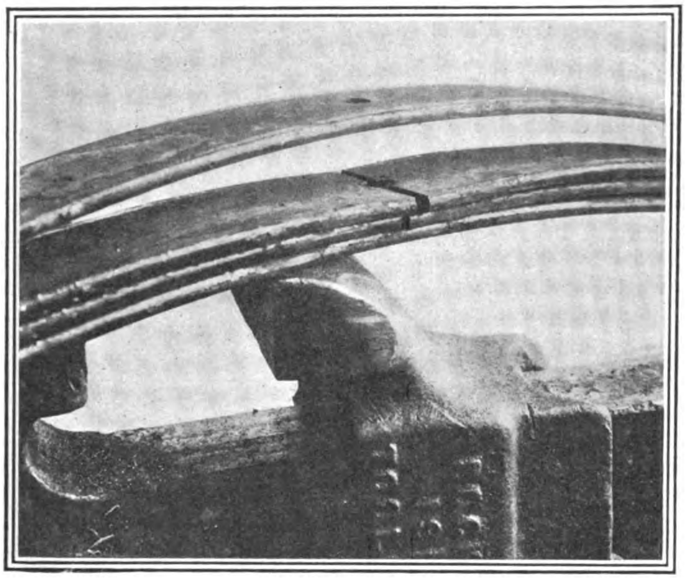

Fig. 3—Spring broken from excessive strain. Note position of bolt hole

Noise and its accompanying imperfections are rapidly being eliminated from the automobile, and smooth-running qualities are being substituted for the minor faults that cause the small annoyances which will occasionally be exposed. Progress in the lines of construction is still on the march, and in the elimination of noise and other sources of inconvenience the greatest steps in advance are being made. In the early days the fact that the motor would run for a large number of miles without a hitch was considered the greatest factor in the development of the car, and all other things were naturally secondary. Now that the number of roadside repairs has been reduced to the point that they consist almost entirely of tire changes, greater attention is being given to the little refinements which tend to the bettering of the running qualities and the silencing of the motor.

The matter of carrying tools has been given considerable attention in the later models of cars, and the ideas of the makers vary to a large extent on this detail. The placing of tool boxes on the running board has not met with the approval of a number of people who drive cars. It is also inconvenient to have the tools placed in such a position that the passengers in the car will have to get out upon the road in case a stop is made to effect a minor repair.

The placing of the different appurtenances of the car has not so much to do with its well-being as the adjustment and fitting of these details when they are placed upon the machine. A squeaking body is just as annoying as a noisy motor even if it does not give the same indication of weakness and faulty design. The manner of supporting a weight should be sufficiently stiff to hold it against the vibrations of the car, and in the fitting of accessories of any description the method of fastening the same should be made a matter of great care on the part of the person who is doing the work. As mentioned above, the derangement of a minor part may often be of great influence in destroying the action of the entire machine, and the derangement is generally due to either inadequate fastenings or, as in the case of the fan bracket mentioned, the facilities for holding the part may be entirely adequate, but through neglect the holding-down bolts or other parts may become loose and the integrity of the part destroyed.

The greatest enemy to the best efficiency of a motor is inaccessibility, for it is in this that the reason lies that the adjustments are not made. Very often a slight knock, which would be adjusted immediately if it were easy to reach the affected part, is allowed to continue until a permanent weakness is developed in the motor and extensive repairs are necessary to restore the motor to its original condition. An inspection cover fastened over parts which are subject to wear or other damage will in many cases be the instrument of salvation to parts which would otherwise rarely if ever be examined.

There are some defects in a car which may gradually develop without the cognizance of even the most careful driver. These generally terminate in a breakdown upon the road and may have results which are very serious. A sudden swerve may put a strain upon the steering knuckle, for instance, which may tax it very nearly to the limit of its capacity. When this strain due to the swerve is supplemented by the shock caused by a rut a break would be very apt to ensue which might result seriously if the car were traveling at a rate which rendered it impossible to stop immediately, for a broken steering knuckle is distinctly beyond the scope of roadside repair.

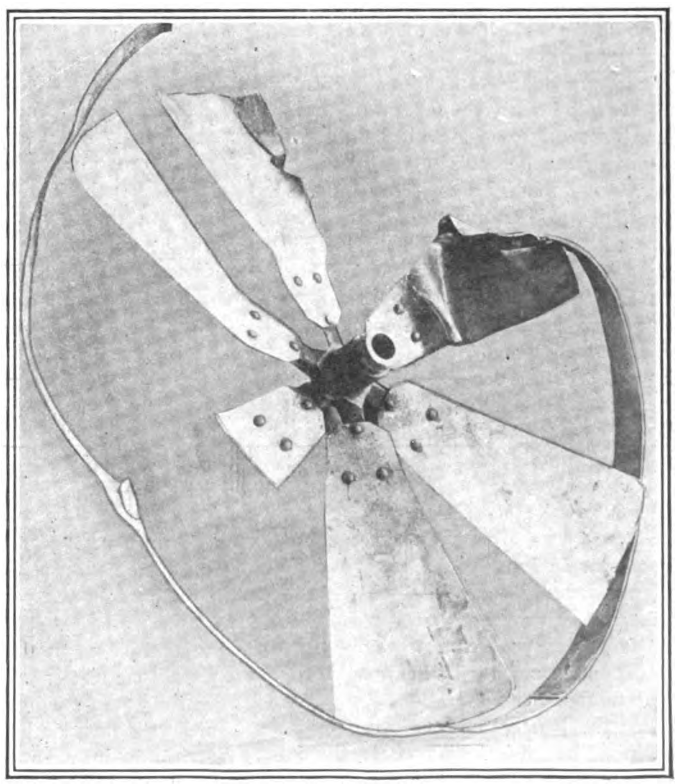

Fig. 4—Showing a demolished fan which resulted from a loose fan bracket

Little Bits of Motor Wisdom

Pertinent Pointers for Repairman and Driver

OUTFITTING THE HOME SHOP—One of the most fascinating pursuits to those who are in any way mechanically inclined is to spend a rainy day in the shop making the repairs that seem to be necessary and the little refinements which, although not a necessity, add greatly to the well-being of the car. The home shop may vary from a mere barn with a few commonplace tools to the elaborately fitted building with a forge and power machines. The latter will, of course be an extraordinary case, but between the two there is a range which will include any shop which the private owner may install.

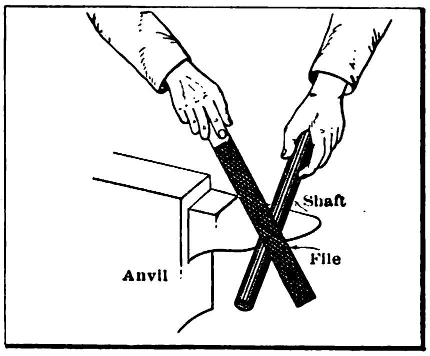

Fig. 1—Illustrating method of decreasing the diameter of a shaft by hand

There are many operations which can be performed with the ordinary tools of which the average owner will be possessed; that is to say, the tools which are not operated by machinery, but which depend entirely upon the handiwork of the operator. These will include the bench tools such as files, chisels, a vise, valve-grinding equipment and all the other appurtenances of the ordinary home shop. A few heavy tools may also be among the outfit if large repairs are to be occasionally undertaken. The most useful among these larger tools will be the forge and anvil, as many repairs which could be very easily made by the car owner or the private chauffeur, if the garage or shop were equipped with some apparatus for heating the metal, will otherwise have to be sent out. The garage is usually equipped with a gasoline torch, with which most of the small jobs such as soldering, etc., can easily be performed; but for other and larger work the torch is inadequate.

After the bench tools and the forge the next in order of importance is the lathe. The lathe may, in a great many ways, be more important than the forge, but since the installation of a driving plant is necessary before the lathe may be properly operated it involves quite an expense and one which would not be justified unless the owner intended to do a large amount of work. There are so many duties to which a shop could be put, by the out-of-town proprietor, especially, that such an expenditure would no doubt be justified, inasmuch as the same machinery for driving the power plant could be used in pumping water, churning and all the various operations consequent upon the upkeep of the country house. Electric lighting is used in the modern suburban house, and when such is the case the same current which supplies the house could be carried to the garage and employed to drive the machinery installed.

A lathe, drill press and blower fan for the forge could all be operated from the same motor to good advantage, and the same belting could be used to operate the pump and the churn. When installing the belting and machinery, the work should be done by one who is an expert in the line, as the subsequent saving of time and space, not to mention the factor of safety, would well repay the extra expenditure involved in the employment of a capable man. The manner of arrangement of a shop and its lighting will determine to a large extent the time and cost of making the various repairs. This is just as much, proportionately, in the case of the home shop as it is when the larger calculations of the manufacturing plant are involved.

The bench should be as long as the confines of the shop will allow and should be well equipped with vises. It should be divided so that certain classes of work are carried on at fixed parts of the bench and the corresponding tools so arranged as to be handy for the class of work to which they are adapted. If vises are clamped to the bench at about three different places along its length they will go a long way toward saving the time and steps of the person who is making the repair.

THE GRINDSTONE—The dull-edged tool is the most unsatisfactory thing to be encountered in the shop. It is dangerous to handle owing to its marked tendency to slip and inflict a gash upon the user, and it is unsatisfactory in regard to the quality of work produced by its use. A dull tool, although not adapted to the cutting of material, is in every way fully qualified to inflict an ugly wound upon a human being and should hence be dispensed with.

The primary instrument in the grinding of tools is the grindstone. The grindstone is driven either by hand, pedal or power through a belt. When driven by hand it requires two to perform the tool-sharpening operation and is for this reason very unsatisfactory. The hand-grinding instrument can readily be changed to the pedal variety, which is a step in advance. The last and best, the power-driven stone, is generally found in shops which are equipped with other motor-driven tools. There is always a method of feeding water to the surface of the stone while it is performing its work. In the hand-driven variety the person turning the stone has the added duty, as a rule, of occasionally pouring water from a handy can upon the surface of the wheel. Or, as is generally done in the foot-propelled variety, a bracket is arranged and the can hung upon it; a hole is then punched in the bottom of the can, which allows the water to leak through fast enough to keep the stone thoroughly wet. In the power-driven wheels the water is generally led through a pipe with a valve by means of which the supply of water may be varied to any degree.

The stones in common use are composed of a gritty form of sandstone known as English, Nova Scotia, Ohio and Huron varieties. The stone should be of uniform composition, fairly soft and coarse, and when used should be revolved so that about 500 linear feet of stone pass the edge of the tool in a minute. This would mean about 80 revolutions per minute of a stone of 2 feet diameter. In the case of a hand-revolved stone it would require a man of very fair strength and endurance to maintain this surface velocity for the length of time required to complete any extensive grinding. Although water is employed on the stone while it is performing its work, it should be turned off the minute

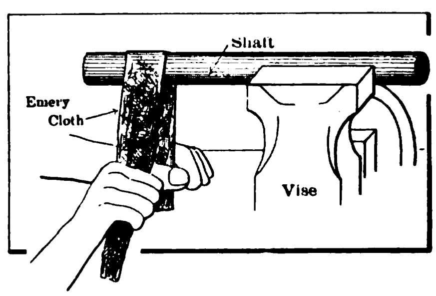

Fig. 2—Rubbing shaft with emery cloth when work is done without a lathe

the work is completed and never be allowed to flow upon the stone while it is not in use. The stone should be kept in a warm, dry place, but not exposed to the rays of the sun, as this will harden the stone to a great degree and do it material harm, as it is at its best when soft.

A tool rest, generally clamped to the frame of the grindstone should be provided, against which the work is held while the operation of grinding is taking place. The stone should always be turned toward the operator and the tool to be ground placed against the tool rest. The motion of the grindstone will tend to pull the tool down with it, but the rest will take up this pull, allowing the operator to confine his attention to the edge of the tool.

On the power-driven wheels there is generally a truing device clamped to the opposite side of the frame from the tool rest. When it is desired to true the wheel the device is brought against the face of the stone and held in position by the clamp. When there is no truing device fitted, the adjustment may be made by hand by placing a piece of pipe or an old file edgewise against the wheel, having it rest upon the tool rest and moving it slowly back and forth across the face of the wheel while it is revolving. No water is played on the wheel during this process.

Sharpening Tools—All edged tools require an occasional sharpening to maintain their condition and efficiency. Tools should not be put away while dull, but on the completion of a piece of work if they have lost their edge they should be ground or at least worked upon an oil stone if that is all that is required.

In grinding a tool the grindstone is set

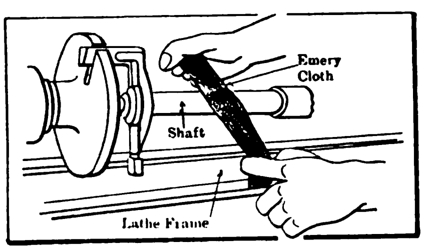

Fig. 3—Method of applying emery cloth to shaft when reducing the diameter

in motion so that it is turning toward the person performing the operation. The tool is then grasped firmly and placed across the tool rest at the proper angle. This angle must be maintained during the whole operation of grinding the tool, as it would be very detrimental to the quality of the edge obtained if the tool were to be shifted a number of times during the operation. The tool rest should be brought very close to the wheel so that there is no possibility of the tool becoming wedged between the stone and the frame in a moment of carelessness or owing to some inequality in the surface of the stone.

After all these precautions have been observed the tool is brought to bear lightly against the stone with the fingers placed in such a way that the delicacy of touch required in careful grinding is obtained. The heel of the edge is made to touch the stone first, and then the tool is tilted up until the correct angle is obtained. The tool is then held steadily at that angle and worked slowly back and forth against the surface of the stone so that any wear on its surface will be made as uniform as possible, otherwise there will be a marked tendency to wear grooves into the stone, which would greatly interfere with the accuracy of the work.

After having ground the tool to the required edge it is plunged into water and then worked across an oil stone or other fine stone which will put a finished edge on the tool. Lathe and special tools require special processes, according to their shape and use.

Fitting of Parts—In the careful fitting of parts, which is often necessitated when extensive repairs are undertaken in the private shop, it is sometimes a question whether the more delicate operations should not be sent out to better-equipped shops for more experienced hands to do the work. There is no doubt that in careful fitting, where the work must be exceedingly accurate in order to obtain the best results, the more elaborate tools will make the work much easier to perform. If the fitting of a shaft were taken for example, it would seem that in order to bring it down to correct shape it would first have to be filed, as shown in Fig. 1, and then, after this long, tedious work is finished, a piece of emery would be called into service to finish the work, as shown in Fig. 2. In hand-filing the shaft, the work could be laid across an anvil or a vise and lightly filed while the shaft was continually turned by the hand, in which it is held. After it had been brought approximately to shape by this method, which is depicted in Fig. 1, it would be placed in a vise and a piece of emery worked across the metal to remove the inequalities which would have resulted from the filing process. When using the emery cloth a long strip should be taken, as shown in Fig. 2, and rubbed across the shaft from one end to the other. The shaft should be frequently turned so that the same amount of material will be taken off on all sides. The shaft is then calibrated along the length required and any apparent inequalities removed.

If the same process were to be carried out with a lathe, the operator would merely have to center the piece of shaft to be turned down, set the tool so as to perform the work, and put the lathe in motion. The lathe is so arranged that the tool is carried slowly along the work in a planer parallel to the axis of rotation of the shaft and always at a uniform distance from it. At the end of this operation the shaft will have been turned down to the thickness desired by the operator. If it is not required to take very much metal off the shaft it is merely necessary to use the emery cloth. The shaft is allowed to rotate at high speed and the emery held against it as shown in Fig. 3. If a fair amount of metal is to be taken off, the emery cloth may be of the coarse variety at first and afterward supplemented by cloth of a finer quality. In using emery cloth which is coarse, great care must be taken that it is not used too long, for if this is done scratches will be made so deep that they will be found in the finished product. Where great care is not so essential, and still a fairly uniform amount of metal has to be taken off the surface of the shaft, it may be placed in the lathe and rotated,

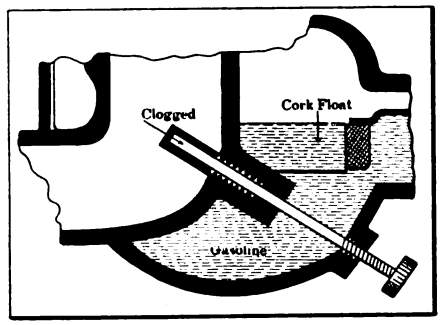

Fig. 4—Section through carbureter, showing needle valve which is apt to clog

with a file held lightly against the surface. Frequent calibration should be resorted to in this case in order that the work be done as uniformly as possible.

There are many other cylindrical parts which may be placed in the lathe for polishing as well as turning down. This is the case only with cylindrical parts, however, as owing to their shape the polisher may be merely held against them as they rotate in order to accomplish the desired result.

Watch Carbureter Needle Valve—The carbureter needle valve is about the most delicate part of this piece of mechanism, inasmuch as it is very apt to become clogged on the slightest provocation. The ounce of prevention in this case is to carefully watch and strain the gasoline that is placed in the tank. The gasoline outlet pipe will no doubt be provided with some sort of screen to prevent the passage of particles of dirt through the gasoline line, but at times a minute particle will pass through the meshes of the screen and find its way into the valve. A piece of cotton waste will very often become lodged in the needle valve in this way and stop the motor. The needle valve is illustrated in Fig. 4, which shows a section through a carbureter, and the clogging takes place at the point shown in the cut. The needle valve may be removed by unscrewing the knurled handle in a carbureter of this or similar type. A very fine wire is then passed through the orifice in order to free it of the foreign matter.

Digest of the Leading Foreign Papers

SHARPENING OF TOOLS BY ELECTROLYSIS—The author points to the actual industrial uses of electrolysis or electro-etching as an indication that the same principle might be applied extensively for the sharpening of tools, but does not enter upon the question whether the acid would affect the properties of the tool steel as referred to in other recent research work. The effect of an acid on metal is increased when at the same time an electric current flows from the metal into the acid, the current always keeping the metallic surface clean for attack by fresh acid. This desirable current may be generated either by forming a galvanic element in the work itself by the addition of one or more pieces of charcoal and suitable wiring, or else, as has been found much more practicable, by connecting the metal with the positive and the acid with the negative pole of any independent direct current. In electro-etching the mass of metal etched away at any one spot depends not only on the duration of the etching and the acidity of the fluid but additionally upon the amperage per square centimeter which passes through the spot into the acid, and this amperage, which in turn depends upon the resistances in the circuit, cannot practically be brought under control unless an independent current source is used. The time required for a certain desired effect cannot be judged in advance with any degree of certainty. For this reason, and also because the acid affected the charcoal and produced a coat of mud over the work which had to be cleaned off at intervals, the methods used by Barthel in New York many years ago for sharpening flat tools and milling cutters by electrolysis in a bath which generated its own current did not prove altogether successful despite of great ingenuity in the arrangements. The change to the use of an independent battery has been universal, and for most purposes one of two to three volts is sufficient. When the current is thus generated externally there is also no need of using such sensitive material as charcoal in order to obtain a maximum of electromotoric force, but other more sluggish materials can be chosen. Grathwohl, of Herisau, Germany, thus uses lead for the cathode and sulphuric acid of 1.18 specific gravity for his patented method for restoring completely worn out files to usefulness by electro-etching. Hall and Thornton, of Birmingham, have produced sharp points on metal tubes and rods by connecting them with the positive pole of a battery and placing the end to be pointed in the acid solution, the latter being connected with the negative terminal, and then pulling the work out of the bath very gradually. The rods in this way became thinner and thinner toward the end. In the same manner thousands of needles could be pointed at the same time in a single trough by simply draining the acid off very slowly. A further development of tool sharpening by electrolysis is possible when the tool is not immersed in the acid solution but is brought in contact with it only where the etching is required. This may be done as follows: A piece of porous burned clay, shaped as the cutting edge to be produced in the tool, is soaked in the acid solution and connected with the negative pole of a battery and is pressed gently against the tool which is connected with the positive pole. After a little time the forming electrode is removed; the tool is brushed free from the alkaline crust which has been formed by the etching, and the forming electrode is soaked again with the acid solution and is again pressed against the tool. With a machine working on this principle the Electrogravüre Company, of Leipsic, has etched whole bas-relief friezes in metal. Burdett, of Hartford, etches ornamental designs and inscriptions into knife blades and metallic surfaces generally by the following method: The surface is painted with a mixture of 101 naphtha, 0.125 kilogram carbonate of sulphur, 2 kilograms powdered resin and 1.5 kilograms of chlorid of copper, and into this coat the design is pressed by means of a die which before each operation is cleansed in a potash solution. Parts of the coat which are loosened by the application of the die are washed off with water and the whole coat is then painted with a weak solution of ammonia or brine; then a clean smooth metal plate is laid upon it and is connected with the negative pole of a battery while the work is connected with the positive. The electric current now passes exclusively along those depressions or lines in the resin which were made by the die and are filled with electrolyte and, shortly, the design is etched out sharp and deep. The surface is then washed clean with a soda solution. Simple arrangements suffice even for work on a large scale.—Erich Schneckenberg in *Werkstattstechnik*, August.

CEMENTING STEEL WITH OTHER SUBSTANCES THAN CARBON (from an article on the Theory and Practice of Casehardening to Date by the well-known authority, Léon Guillet)—If chromium, tungsten, molybdenum or vanadium could be introduced superficially in iron or steel, tool steels and construction steels of high grade could perhaps be produced at a low cost (the machine work being done on soft material and the quality raised by the introduction of alloys, as carbon is now introduced by the casehardening process). Leaving aside the different false ideas which have gained currency, relating to the employment of nickel salts, of chromate of potassium, etc., it is now being assured us from divers sides that, so far as tungsten is concerned, the problem has been industrially solved. The author does not know either the method followed or the results obtained, he says, but only repeats a rumor persistently heard. [In the United States a large company is in the process of formation which is to undertake the "infusion" of several other alloys besides tungsten, and to transform pieces shaped from common Bessemer steel or even from wrought iron or pot metal into corresponding pieces possessing all the properties which could have been secured at higher cost by using high-grade alloy steels for the manufacture of the parts in the first place; and the company exhibits a large variety of parts and tools, including milling cutters, which have been obtained from many different manufacturers and have been so transformed.—Editor.]

The experiments which the author has made to obtain the penetration of nickel into steel have produced absolutely negative results. He has nickeled pieces of steel and has left them in a furnace at 1000° without any effect, even after very prolonged heat. He has also sought to employ "nickel-carbonyle," but the low temperature at which this substance decomposes and the dangers incidental to its use made him abandon these trials. Experiments with iron and aluminum, on the other hand, which were undertaken on the advice of Henry le Chatelier, gave very plain penetrations. A piece of aluminum fitted in the center of a piece of hollow steel showed considerable penetration at a heat of 450°, which is far below the fusion point of aluminum. But it does not seem possible to derive interesting industrial results from this fact. Copper, in very recent tests, gave a slow penetration, recognizable by the microscope, however. All this shows the way to important research, and the difficulty is assuredly to find suitable gaseous compounds or else to make sure by other means of close contact between the steel and the substance one wishes to bring into "solid solution" therewith. These difficulties are in reality the same which are experienced when it is attempted to dissolve pure carbon in iron (instead of using the bonemeal or other casehardening compound).

With regard to other metals than iron, the formation of a solid solution of one metal or substance with another seems theoretically plausible whenever the two substances are completely miscible. The only actual experiences in this direction which the author can cite are the following: A bar of bronze containing 7 per cent. of tin was fitted closely in a tube of bronze containing 16 per cent. of tin. After heating to 800° for 8 hours, the bronze originally containing 7 per cent. of tin showed a tin content of 9 per cent. (corresponding to the "delta" class under the spectroscope), and the tin content increased toward the joint between the two bronzes, just as pearlite in a cemented steel. Again, a condenser tube of "alpha" brass which had been tinned showed, after a heat which probably did not exceed 150° C., the characteristic "delta" constituent of tin-brasses. The author repeated this experience, heating an "alpha plus beta" brass of 60 per cent. copper after having tinned it, and then saw in the black zone of "beta" the "delta" constituent which is characteristic of the presence of tin. Finally, Mr. Masiny has shown, by the variation in electric resistance, that lead and thallium, when brought in contact, penetrate mutually, beginning at ordinary temperatures, and that the speed of penetration is clearly emphasized at a temperature of 100° C. The industrial process known as "sherardization" belongs in the same class of phenomena. It consists in placing steel forgings or castings in commercial zinc powder at a temperature of 300° C. The result is a "galvanizing" of very pretty patina and very durable, and trials have demonstrated that the process is one of real cementation by the solid (though powdered) zinc, taking place only where the powder and the steel are in real contact.

Only 15 years ago, says the author in summarizing his treatise on casehardening, a trough heated with coke was placed on the floor of the shop and the pieces to be hardened were stuck into a queer powder compounded from cows' horns, hog suet and urine, but it has now advanced to be a scientific process to be practised under close observation of intelligent rules for adapting means to ends.—*Le Génie Civil,* August 5.

ACETYLENE GAS EASY TO IGNITE IN RICH OR POOR MIXTURES—According to experiments conducted by Prof. Eilner, a mixture of air and acetylene gas begins to be explosive at a 2.9 percentage of acetylene, and the explosiveness continues up to a percentage of 64. Other experiments on a much larger scale by the Electrical Society of Bosnia place the low limit for explosibility at 2.5 per cent. to 2.6 per cent., and at 3 per cent. the explosions became violent enough to shake the solid masonry which confined 11 cubic meters of the gas mixture and had been erected for the purpose of the experiments.—From *La Rivista tecnica d'Italia.*

VIENNA'S FOUR-IN-ONE MUNICIPAL MOTOR WAGON—The municipality of Vienna has acquired a motor vehicle of a new type which can serve as a sprinkling wagon, a fire engine, a street sweeper and as a simple 6-ton truck. To transform the sprinkling wagon into a fire engine it is only necessary to start a separate motor, operating independently of the motor power, and to attach a fire hose to a universal screw plug on the pump. A simple movement lets down the sweepers which operate like the snow ploughs of the street car companies, and when the water reservoir is dismounted, the city has at its disposal an ordinary 6-ton truck.—*Automobile-Aviation,* September 21.

BOOM FOR HEALTH RESORTS BY EXCLUDING THE FLY BREEDERS—"We should like to propose to some landowner who is anxious to found a seaside resort that he should try the experiment of making it into a real health resort by banishing the horse from its precincts. Nowadays public opinion is sufficiently advanced to realize the benefits of air free from impregnations of animal filth, and we believe there are distinct possibilities in a horseless health resort. We do not merely mean possibilities of health, but possibilities of establishing a town which would be appreciated, and to which visitors and seekers for health would betake themselves simply because they would realize that proper precautions had been taken to preserve the air from contamination."—*The Autocar,* Sept. 16.

EUROPEAN AGRICULTURAL INTERESTS DEMAND MOTOR IMPLEMENTS NOWADAYS—The French Association for Motor Agriculture (*Association Française de Moto-Culture*), recently held a competition for agricultural automobiles at Melun. The machines represented were: One tractor of 25 horsepower, which turned over the soil when hitched to a plough with five shares and with equal facility actuated a harvester with three binders; one tractor for heavy work; one winch-truck; one automobile disk-plough; one automobile breaking-plough; two self-propelled hoeing machines and two self-propelled cultivators.—From *L'Automobile Belge,* August 30.

Calendar of Coming Events

Shows

Oct. 7-14..........Chicago, Ill., Show of Chicago Automobile Trade Association.
Jan. 6-13..........New York City, Madison Square Garden, Twelfth Annual Show, Pleasure Car Division, Automobile Board of Trade.
Jan. 6-20..........New York City, Madison Square Garden, Annual Show, Motor and Accessory Manufacturers.
Jan. 10-17........New York City, Grand Central Palace, Twelfth Annual Show, National Association of Automobile Manufacturers; also Motor and Accessory Manufacturers.
Jan. 15-20........New York City, Madison Square Garden, Twelfth Annual Show, Commercial Division, Automobile Board of Trade.
Jan. 27-Feb. 10....Chicago Coliseum, Eleventh Annual Automobile Show under the auspices of the National Association of Automobile Manufacturers. Pleasure cars, first week. Commercial vehicles, second week. Accessories, both weeks.
Feb. 19-24........Hartford, Conn., Annual Show, Automobile Club of Hartford, State Armory.
March 2-9.........Boston, Mass., Tenth Annual Show, Boston Automobile Dealers' Association, Inc.

Meetings, Etc.

Nov. 20-24........Richmond, Va., First American Road Congress, under auspices of American Association for Highway Improvement.
Nov. 23.........Road Users' Day, under direction of Touring Club of America.
Jan. 18-20.........New York City, Annual Meeting of the Society of Automobile Engineers.

Race Meets, Runs, Hill-Climbs, Etc.

Oct. 7...........Danbury, Conn., Track Races, Danbury Agric. Soc.
Oct. 7............Springfield, Ill., Track Races, Springfield Automobile Club.
Oct. 9-13..........Denver, Colo., Reliability Run, Denver Motor Club.
Oct. 10............Bedford, Ind., Hill Climb.
Oct. 11............Oklahoma City, Okla., Reliability Run, Oklahoma State Automobile Association.
Oct. 12-13.........Peoria, Ill., Track Races, Peoria National Implement and Vehicle Show.
Oct. 14............Santa Monica, Cal., Road Races.
Oct. 14 (to 25)....New York City, Start of the Annual Glidden Tour, en route for Jacksonville, Fla.
Oct. 16-18.........Harrisburg, Pa., Reliability Run, Motor Club of Harrisburg.
Oct. 21...........Atlanta, Ga., Track Races.
Oct. 27-Nov. 3.....Chicago, Ill., Thousand-Mile Reliability Run, Chicago Motor Club.
Oct. 31............Shreveport, La., Track Races, Shreveport Automobile Club.
Nov. 2-4...........Philadelphia, Reliability Run, Quaker City Motor Club.
Nov. 3-4...........Columbia, S. C., Track Races, Automobile Club of Columbia.
Nov. 4-6...........Los Angeles-Phoenix Road Race, Maricopa Auto Club.
Nov. 9.............Phoenix, Ariz., Track Races, Maricopa Automobile Club.
Nov. 9, 10, 12....San Antonio, Tex., Track Races, San Antonio Auto Club.
Nov. 27...........Savannah, Ga., Vanderbilt Cup Race, Savannah Automobile Club.
Nov. 30...........Los Angeles, Cal., Track Races, Motordrome.
Nov. 30...........Savannah, Ga., Grand Prize Race, Savannah Automobile Club.
Dec. 25-26.........Los Angeles, Cal., Track Races, Motordrome.

Foreign Fixtures

Oct. 12-22.........Berlin, International Automobile Exhibition.
Nov. 3-11.........London, Eng., Olympia Show.

THE AUTOMOBILE

Vol. XXV Thursday, October 5, 1911 No. 14

THE CLASS JOURNAL COMPANY

H. M. SWETLAND, President

CONDE NAST, Vice-President and General Manager

E. M. COREY, Secretary and Treasurer

231-241 West 39th Street, New York City

Cable Address - - - - - - - - - - - - - - - Autoland, New York
Long Distance Telephone - - - - - - - - - 2046 Bryant, New York

SUBSCRIPTION RATES

United States and Mexico - - - - - - - - - - - - One Year, $3.00
Other Countries in Postal Union, including Canada - - - - One Year, 5.00
To Subscribers—Do not send money by ordinary mail. Remit by Draft, Post-Office or Express Money Order, or Register your letter.

Entered at New York, N. Y., as second-class matter.
The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

Our Babies

THE progress of automobile design in America has been hampered by the babies of the engineers, by the babies of the factory heads and by the babies of some influential stockholders. There is scarcely an engineer but has had his babies in the field of design. Each has had his pet designs. One engineer started out with a method of controlling valves in the early days of the industry. He conceived the idea and consequently held on to it until the wolf was near the door. Sheer necessity then made him give it up. The giving up of it was like amputating a part of himself. He had nourished it from its inception; to him it was the only method of control that could be right; it was the type that would exist when all others were forgotten; and he could see no other one. Other makers controlled in the carbureter; the public of France at that time demanded throttle control; it was gaining on every hand; but the engineer stuck to his baby until it was a case of give it up or get out. He deserted it.

The babies of the automobile industry have not all lived in France—America has had a good many of them. One engineer had his own type of axle; he took out the patents on it; he manufactured it; he introduced it, and he died for it. He had eyes for it and for nothing else. The design was passably good; it gave a measure of satisfaction; but it was not what the masses wanted. The engineer dictated the policy of the factory; he was the Alpha and Omega of everything pertaining to engineering in that company, and the company stuck to the axle and to the engineer until its sales dwindled and dwindled. One after another of its best men joined other more progressive companies, but still the engineer and the factory stuck to the baby. At last money became so scarce that it was death or the baby; then, and only then, was the baby dropped Since then the company has been slowly gaining. It learned the lesson: "Do not stick too long to the baby."

One factory manager preferred complete business extinction to the surrender of his baby. It was a method of control and body design. It was excellent; from the scientific viewpoint nothing better could be wanted; but the people did not buy it. The business grew smaller and smaller; soon the factory force dwindled to a mere handful of workmen; new capital was looked for and secured—but the baby was retained; a month or so later the low mark was reached; a receivership ended the agonies. It was a double funeral.

One concern started in the manufacturing field of cars with triplets. It had a special ignition scheme, different from all others, and it took a salesman 15 minutes to explain it. The system worked well, but it was roundabout and had many needless parts. The car also had a cantankerous method of lighting the headlights from the seat. It, too, was different. According to the inventor it was going to revolutionize car lighting—but it failed. This automobile had a self-starter; self-starters are good, everybody is after them to-day, but in those days nobody wanted them. The engineer was going to make the people not only want them but use them—he failed. The company stuck to all three babies. The engineer had invented them all; they were dear to his heart and he would not give them up. The company soon afterwards failed.

But the babies of the automobile business are not all gone yet. There are scores of them still living and being guarded fearfully by the engineer, or the factory head. Some of them to-day are in the form of carbureter schemes; others are frame designs; some are lubrication contrivances; some are gearset eccentricities; some are brake designs; some body whims, and others steering features. These babies are all expensive. In many cases it has necessitated special machinery to manufacture the special parts. This machinery has cost money and so is an expense. The biggest expense of all, however, is in the expenditure of energy in selling the article. There are companies to-day that have their salesmen spend 25 per cent. of their energy in convincing the buyer on one point, the imagined value of the baby. This is poor policy; it is short-sighted policy. This policy was all right a few years ago when selling cars was confined to filling out orders, but it is not all right to-day. This is a day of competition. This is a day when salesmanship is needed and the best salesmanship will not sell machines with inferior designs. What is needed to-day is good design and not the whims of an engineer.

There are more whims and babies in many American cars than in many of the European types. The foreign car may show much in the line of versatility of design, but the whim is not so apparent. The reason is at hand: The majority of the big foreign factories have a corps of graduated engineers—they are not so scarce as in America. These engineers meet together and they meet with the directors of the company. They meet in hot discussions. One engineer may have his babies; he wants his pet designs incorporated into the car; the other engineers discuss and oppose it, and the net result is that pet ideas are eliminated to a much greater extent than in a factory, like so many of the American factories, where the engineer is the only person who has anything to say in the field of design. He has to be a gilt-edge engineer who can dictate all that is best for a car. He may be an expert in gasoline engine design but a pigmy when it comes to designing a steering gear; his principles may be excellent for brake design but wrong in gearset work. So it is all through the car which is the product of one man; the car is certain to have its weaknesses. A corps of three or four engineers is always much better than one. These engineers can at least see the design, under question, from three or four different angles; one should be able to pick out some weaknesses that the others might pass over; a second one will be able to suggest some detail that when added will be an improvement; and so through the entire car. If a factory cannot support its corps of engineers it might be able to support a consulting engineer, or aid in supporting one. The calling in of other physicians is considered the best policy in cases of dangerous illness. Why cannot the same thing be tried out in car design? Some of the most progressive makers are doing it to-day and they are profiting and saving money by it. More will be doing it before two years have elapsed.

It is cheaper to employ two or three engineers than it is to pull a design to pieces every year or so. It costs money to make dies for forgings; it is expensive to change the cylinder designs and have to alter the patterns; it is expensive to make new jigs each season, and it is expensive to buy new machinery or alter the old to take care of the annual changes. Many of the changes that are imperative each year are due to an overworked engineer, or to one with his pets. With the board of directors of the factory it is short-sighted policy to let a single engineer dictate, when the better judgment of many of the board says that certain changes should or should not be made. There are cases on record to-day where engineers are obstinate. They will not change because some other engineer has beaten them to a certain design. Such persons are equally dangerous. The solution is a corps of engineers or some good consulting engineers. Our factories are going to come to one or the other very soon. It is imperative with some of them; with others the policy will be dictated by good judgment. There are not a few wrecks on the sea of automobiling to-day, due solely to an engineer running away with the factory. The wise, far-seeing factory head is watching this problem.

S.A.E.'s Foreign Trip

ARRANGEMENTS for the foreign trip of the Society of Automobile Engineers are occupying an important part in the thoughts of members of the organization. So far 37 have signified their intention to make the trip if possible and about half that number have definitely arranged to go. At the meeting of the organization Wednesday a tentative program was framed covering a visit of 23 days, as outlined previously. Howard E. Coffin will make an address in London on chassis design.

The place in which the annual meeting will take place in New York was considered and it is likely that the Automobile Club of America will be chosen again.

Reeves Outlines Scope of Industry

Alfred Reeves, general sales manager of the United States Motor Company, in a lecture delivered before the West Side branch of the New York Y. M. C. A. recently, gave out the following statistics with regard to the automobile industry:

"155 factories are now beyond the experimental stage and producing 50 or more cars a year.

"65 companies are now producing motor trucks or commercial vehicles exclusively.

"405,000 cars registered as being in active use in the United States at the present time, with probably 50,000 more cars used where State registration is not required.

"190,000 cars sold during the past twelve months.

"210,000 pleasure cars scheduled for the next twelve months.

"9,000 trucks and delivery wagons now in use.

"18,000 trucks and package delivery wagons to be made in the next twelve months.

"11,400 dealers selling cars in every town of any importance in the country, with a very much larger number of garages.

"82,166 motor cars registered in New York State.

"32,400 chauffeurs registered in New York State.

"$20,000,000 in motor cars and parts will be exported during 1912, based on Government figures for the first seven months."

Outdoor Show at Mound City

ST. LOUIS, Oct. 2—An out-of-doors exhibit marked the opening of the fifth annual Automobile Show of the St. Louis Manufacturers' and Dealers' Association, which began at Forest Park Highlands, a summer amusement resort, Monday night. The early date of the show is due to the fact that the Veiled Prophet Festival is being put on the same week.

Fire-Fighters Parade

THE budget display of automobile fire apparatus owned by the city of New York was held Tuesday in front of the City Hall. Eighteen pieces of apparatus were in line, including all those specified and described in a recent article in THE AUTOMOBILE. Aside from the actual fire-fighters there were a number of runabouts and raceabouts used by battalion chiefs and executive officers of the department.

Mayor William J. Gaynor reviewed and inspected the display. The present motor equipment of the fire department is a nucleus about which will be assembled a collection of at least 150 pieces of power-driven apparatus by January 1, 1913.

Louisville Plans for Fire Automobiles

LOUISVILLE, Oct. 2—If the chief of the Louisville Fire Department, Timothy Lehan, has his way, the present fire-fighting equipment will be replaced by automobile apparatus. The contemplated change will be made as soon as the horse-drawn vehicles now in use wear out.

Louisville has twenty-one fire stations. At each an engine and hose reel is located. Besides this apparatus there are five hook-and-ladders and a water tower. The only motor vehicle now in use by the department is the one used by the chief. The street railway company, the salvage company and the lighting company all answer alarms in motor-driven vehicles.

According to the chief, one of the advantages of the motor apparatus is that the engine and hose cart can be combined, and some companies are now turning out a successful combination consisting of engine, hose cart and chemical engine.

Knight Entertained at Indianapolis

INDIANAPOLIS, Oct. 2—Charles Y. Knight, inventor of the silent Knight sleeve-valve motor, was the guest of motor car men at the Columbia Club in Indianapolis, on the night of Sept. 29. The occasion was a dinner given in Mr. Knight's honor by Hugh H. Hanna, president of the Atlas Engine Works, which has been licensed to build the Knight motor for the trade in the United States.

Mr. Knight spoke at length of the inception and development of his motor. F. E. Lonas, legal representative of the Knight & Kilbourne Company, was also among the speakers. Mr. Knight's father resides in Indianapolis, and he spent a few days with him, during which he consulted with the officials of the Atlas company relative to the building of the Knight motor.

News of the Week Condensed

AKRON, O.—More than 100 representatives of the sales force of the Firestone Tire & Rubber Company were in annual convention here some days ago. President Firestone in his annual address submitted figures which indicated that last year's increase in sales was the greatest in the company's history. The above photograph was taken in front of the company's immense new plant.

SAN FRANCISCO—The Frank O. Renstrom Company, local distributers for the Regal and Kline lines, has taken the coast agency of the Dart delivery wagon.

CLEVELAND, O.—The Standard Welding Company has opened a branch office at Chicago. The line was formerly handled by L. F. McClernan & Co. in that city.

COLUMBUS, OHIO—The Cummins Auto Sales Company, of North Fourth street, Columbus, Ohio, has closed the agency for the Everitt in six counties in Central Ohio for 1912.

ZEELAND, MICH.—The Zeeland Automobile Company has purchased a new location at Main and Washington streets. The company will move its old building to the new site immediately.

GOSHEN, IND.—Teegarden & Putt will occupy their new garage in that city this month. The new garage is located north of Hotel Hascall, and work is being rushed as rapidly as possible.

INDIANAPOLIS—Charles E. Coots, chief of the Indianapolis Fire Department, has asked the Board of Public Safety to purchase gasoline runabouts for each of the four assistant fire chiefs.

CINCINNATI, O.—The Heilman Motor Car Company is building a garage in Cumminsville. The new place will have facilities for handling 40 cars. The company sells the Haynes and Cartercar.

PORTLAND, ORE.—One of the most up-to-date and finest appointed garages here was recently completed for Thompson & Nation, Speedwell agents. It is located at Couch and Fourteenth streets.

SOUTH BEND, IND.—The Simplex Motor Car Company, of Mishawaka, Ind., has decided to enter two Amplex cars of the latest model at the open-air auto show which will be held in St. Louis, in October.

DAYTON, O.—H. P. Michael, formerly with the Miami Valley Automobile Company, has opened an agency at 16 South St. Clair street, and will handle the Hupmobile exclusively. He will install also a repair department.

SEATTLE—Arrangements were concluded last week by Paul McMullen, Oakland manager for the Hudson and Hupmobile cars, for the construction of a fireproof building at 1511 Broadway, to be completed in November.

DAYTON, O.—H. J. Myers, formerly sales agent for the Baker electric in this city, has been given the agency for the company at Cleveland. His territory includes Ohio, Southern Michigan, Western New York and Western Pennsylvania.

WEST BEND, WIS.—The West Bend Aluminum Co. has been incorporated here, with a capital of $14,000. The company has established an aluminum factory in the old Kress factory buildings. Andrew J. and Edwin Pick and Martin Walter are the promoters.

MARIETTA, OHIO—The Pioneer Motor Car Company, recently incorporated with a capital stock of $18,000, will soon start the erection of a three-story brick building, to be used as salesrooms and garage as well as a repair shop. The building will be erected on Front street, and will be 190 by 58 feet.

OKLAHOMA—Citizens of Grady County, Oklahoma, propose to build their proportionate part of the State road crossing that county in 1 day, October 2. A holiday has been declared for that day, and practically every man of the county has agreed to work that day on the road.

COLUMBUS, OHIO—The Rusk & Hallock Company, North Fourth street, Columbus, Ohio, has closed the agency for the Warren-Detroit for 1912, covering six counties in Central Ohio. The counties in the territory are Franklin, Delaware, Pickaway, Fayette, Madison and Union.

ROANOKE, VA.—The third annual convention of the South Appalachian Good Roads Association will be held here October 4-5. Logan Waller Page, Governors W. H. Mann, Cole L. Blease, Augustus E. Willson and a number of prominent engineering experts are scheduled to speak.

NORTH JUDSON, IND.—The Stark County Garage & Machine Works is erecting a garage here which will be the largest in Stark County. The proprietors are A. C. Ross, of Winamac, and G. A. Spehner, of North Judson. It is expected to have the building completed by the last of October.

DAYTON, O.—George L. Baker and Frank L. Baker have opened an auto livery service at 122 South St. Clair street. George Baker will remain in charge of the retail sales department of the Speedwell Motor Car Company, the new venture having no direct connection with his other work.

SAN FRANCISCO—One of the most interesting automobile changes here recently was the switching of the Apperson agency in Northern California from the Auto Sales Company to the Weeks-Covell Automobile Company, who are also the new Northern California distributers of the Pathfinder and Parry.

PHILADELPHIA—The annual meeting and banquet of the Automobile Club of Delaware County will be held in the new Armory Building in Chester, next Wednesday evening. New officers and directors are to be elected. The organization dates from 1906.

PITTSFIELD, MASS.—The Cortland Motor Wagon Co., formerly of Cortland, N. Y., is in its new plant at Pittsfield, Mass., and have the 1912 output well under way, the first car being on the road. The officers officers are as follows: R. H. Jadwin, president; Tracey A. Rudd, vice-president; Edson T. Starks, secretary and treasurer.

DAVENPORT, IA.—Hite D. Bowman, agent for the Rauch and Lang electrics, Stearns and Chalmers cars, has just completed a $7,000 addition to his garage at Fourth avenue and Oak street. It is to be used exclusively as a place in which to charge, house and repair electrics. A workshop has been installed on the second floor.

GRAND RAPIDS, MICH.—The Palmer Sales Company has secured space with the Hupmobile garage on North Ionia street. Remodeling is going forward rapidly at the Overland Sales Company garage on Island street. George P. Dowling will become the Buick factory's territorial representative for Kent, Ottawa and Allegan Counties.

VANCOUVER, B. C.—Dr. Chas. G. Percival, of New York, in the Abbott-Detroit "Bull Dog," has reached this city, with a total mileage of 32,112 miles to his credit on his trip around the world. He has successfully completed the first authentic trip along the route of the Pacific Highway, from Tia Juana, Mex., to Vancouver, B. C.

MONTREAL—The Hupp Motor Car Company, which has for some time been assembling cars in leased premises at Windsor, Ont., has closed a deal for the purchase of a site including a little more than 3 acres. The company will erect two factory buildings at a total cost of about $525,000, and will start with a force of 150 to 200 men.

WASHINGTON, MO.—At the Franklin County Fair, which was held last week, the Crow-Elkhart car owned by Dr. Otto L. Muench, was awarded first prize for beauty of decoration, which consisted of 6,000 roses, ranging from deep red at the bottom to pink and white at the top, surmounted by a pair of butterflies driven by a little fairy.

ATLANTA, GA.—J. E. C. Edsall, representing the Staver-Chicago car, reached Atlanta this week after a round-about 2,500-mile trip from Chicago. He will for the present make his headquarters in Atlanta and will establish agencies in Georgia. There is reported to be a possibility that a Staver-Chicago branch may be opened in Atlanta.

ATLANTA, GA.—E. P. Horton, formerly representative of the United States Motor Co. in Syracuse, has been transferred to the Atlanta branch, and will hereafter have charge of the United Motor Atlanta Co. L. E. Kloeber, who has been manager of the Atlanta branch for some time past, will soon be transferred to some other U. S. Motor branch.

COLUMBUS, OHIO—The Hudson Sales Company, North Fourth street, Columbus, Ohio, ha taken the agency for 1912 for the Whiting. The territory covers 16 counties in Central Ohio. Sub-agencies have been placed as follows: Springfield, Gaither Auto Co.; Circleville, Mader Auto Co.; Logan, Gage Automobile Co.; Newary, Charles U. Stevens.

COLUMBUS, OHIO—B. F. Myers, connected with the firm of Rusk & Hallock, has secured a patent on a spring shield which will be manufactured in Columbus, Ohio, by a corporation to be organized in the near future. The idea is to have pieces of heavy felt, containing oil, bound next to the spring by a leather casing which is laced from either axle.

AKRON, OHIO—The Olds-Oakland Company, of Cleveland, Ohio, has established a permanent agency for the Oldsmobile and Oakland lines with the Portage Motor Car Company, of Akron. D. W. Thompson, manager of the Portage Motor Car Company, will have personal charge of the distribution of the Oldsmobile and Oakland in Akron and vicinity for 1912.

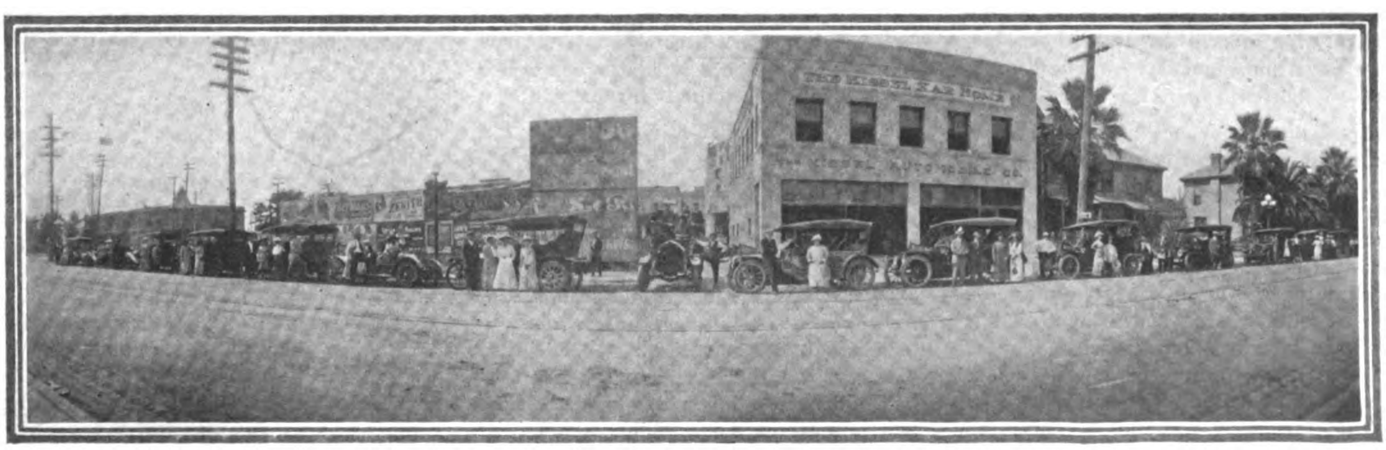
SOUTH BEND, IND.—Montgomery County, Indiana, has some of the finest roads of the State. It has 134 improved roads, built of gravel or crushed stone. These roads were all constructed under the 1905 road law. The cost of constructing the gravel roads is from $2,000 to $2,300 per mile, while the cost of constructing the stone roads is from $3,500 to $4,000 per mile.

SYRACUSE, N. Y.—The third annual sociability run of the Syracuse *Herald* will be held Saturday, October 7, with Mayor Edward Schoeneck as an honorary referee. It is expected that more than 200 cars, many of them driven by women, will participate. A 60-mile run through a picturesque farming country southeast of Syracuse has been arranged, the turning point being at Tully.

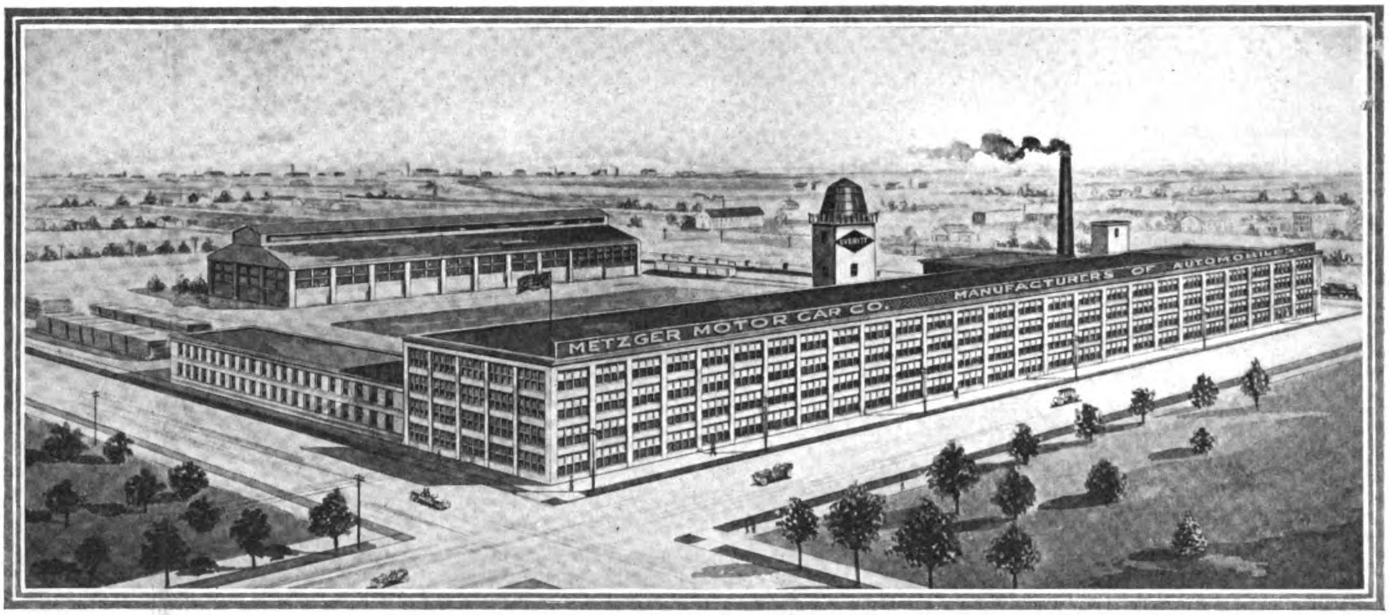
DAVENPORT, IA.—The Buck Motor Car Company, agent for the Packard cars, Packard truck and Detroit electrics, has just moved into a new $13,000 garage. The new Packard and Detroit electric headquarters in Davenport is 45 by 140 feet in dimensions, constructed of terra-cotta and concrete with brick front, with handsome offices furnished in oak and a show room with a capacity of ten cars.

MILWAUKEE—H. L. Kuelling, C.E., University of Wisconsin, '06, has been elected Highway Commissioner of Milwaukee County, Wis., under the new State aid for highway improvement law. As County Highway Commissioner he will supervise the expenditure of an appropriation of $100,000 made by the Milwaukee County Board of Supervisors for road work, which draws an additional $75,000 from the State Treasury as State aid.

SAN FRANCISCO—One of the latest additions to Automobile Row is the Auto Tire Company. This is a branch of the New York firm of that name, which has its subordinate houses throughout the country. The San Francisco house has been established by R. A. Demarest, general manager of all branches. Mr. Demarest has lately established a similar branch house in Los Angeles. The San Francisco house will be in charge of N. C. Dunham.



Panoramic view of a recent tour in California in which only KisselKars took part. There were 22 cars in the 200-mile tour



New building of the Metzger Motor Car Company, at Detroit, Mich., now in course of construction. It is four stories high and 550 feet long

PHILADELPHIA—A meeting of the Board of Governors of the Automobile Club of Philadelphia was held this week, at which twenty-five new names were added to the membership roll and general plans for the proposed new clubhouse and garage of the organization discussed. It is announced that work on the latter will be started before snow flies. The treasurer's report showed the club to be in excellent financial condition.

LOS ANGELES—One of the most novel automobile displays ever projected in the country is under way under the direction of the Los Angeles Order of Mystic Shrine. The automobile show will be held at the Shrine Auditorium, November 6 to 18. Twenty Los Angeles dealers have taken space for the show. A popular voting contest will be held, at which an automobile will be given away.

SYRACUSE, N. Y.—Syracuse dealers in motor trucks are now waging a campaign of education among users upon the danger of the combination of overloading and fast driving. The argument is being made upon these three points, non-observance of which the agents contend seriously menaces the industry: 1. Mechanism suffers when normal carrying capacity is exceeded. 2. Tires wear down more quickly. 3. The life of a truck is shortened by its hard usage.

LOS ANGELES—A new automobile truck factory is to be built here. Announcement was made during the past week of the concern, which will be known as the Moreland Truck Company, organized by W. L. Moreland. The plant will be in operation in 60 days, according to the announcement, and will turn out what is known as a distillate truck from 1 to 5 tons capacity. The officials of the company are R. H. Raphael, president; C. Kubeck, vice-president; Sheldon Morse, secretary and treasurer, and W. L. Moreland, manager.

MILWAUKEE, WIS.—The Pauly-Bruce-Goldaker Co. has been organized to handle the Stoddard-Dayton line in Wisconsin. The State agency formerly was in charge of the McDuffie Automobile Co., of Chicago and Milwaukee. The Stoddard garage at 141-145 Eighth street, is now occupied by the Hickman-Lauson-Diener Co., State agent for the Ford, and the new Pauly company has taken the former Ford headquarters at 222-224 Fourth street.

PORT HURON, MICH.—The Havers Motor Car Company has closed a contract with one of the largest motor concerns in the country for the building of the Havers "Six" motors for the coming season. The contract amounts to approximately $340,000. The company has been occupying about one-half of the plant formerly used as the Malleable Iron Foundry, and alterations are now under way that will make it possible to use the entire plant the coming season.

SYRACUSE, N. Y.—A number of automobilists and dealers from this city plan to accept the invitation of Secretary of State Lazansky to meet with autoists from all over the State at Albany on October 9, to discuss means of increasing interest in automobile touring. Representatives from many Eastern States will also be present, and a uniform statute for non-resident touring privilege will be discussed. The Touring Club of America has been agitating the matter.

MILWAUKEE.—The Milwaukee Automobile Club on Saturday evening, September 30, held the largest stag party since its new clubhouse on the Blue Mound road, at Cottrell avenue, was opened. More than 500 members and their friends participated. The stag was the second of a series to be held during the fall and winter to stimulate interest in the club among motorists who are not yet members, and which is part of the general campaign to make the membership 1,000 before January 1.

OKLAHOMA—The 800-mile route of the Oklahoma reliability run for 1911, which begins October 12, passes through some sections of the State where automobiles are seldom seen, and J. L. McClelland, pilot, who donated the services of his "Hudson 33" as the pathfinding car, states that all along the route the party was besieged by prospective purchasers. In order to give the entrants a chance to meet the prospects, the route book has been made up for short runs, putting the contestants into controls each day in time to talk business.

MISHAWAKA, IND.—The Fostoria Aluminum Manufacturing Company has changed its name to the American Casting Company. The company recently moved to Mishawaka from Fostoria, Ohio, and manufactures automobile castings. The company's plant will be re-equipped with considerable new machinery. At a meeting of the directors held recently the following officers were elected: W. H. Rockoff, president and treasurer; W. H. Gilbert, vice-president, and B. E. Rockoff, secretary. The company expects to operate its plant on a larger scale and is widening its scope of operations.

BOSTON—The annual reunion of the Velie branch house managers, agents, heads of the service stations and salesmen throughout the country, will be held at the Velie factory in Moline, Ill., October 9-15. The new Velie 1912 models will be shown for the first time and questions of interest in the automobile industry will be taken up by the various Velie representatives. The N. E. Velie branch will be represented by Walter B. Johnson, Essex Junction, Vt.; George H. Snell, of Attleboro, Mass.; Arthur Beharrell, of Lowell, Mass., and Harold D. Bornstein, of the Velie Boston branch.

CLEVELAND—The next annual meeting of the Gas and Gasoline Engine Trades Association will be held in Cleveland December 5-8.

DETROIT—The Herreshoff Motor Company is preparing to move into its new quarters on Woodward avenue, between Belmont and Trowbridge avenues.

OMAHA—The Kirkland-Hicken Company has been formed to handle fireproof portable garages and pumping machinery in Nebraska, Iowa, South Dakota and Colorado.

SYRACUSE, N. Y.—W. H. Emond, chief designer of the Franklin company, has left for Europe where he will study foreign designs. He will visit France, Germany and England.

WORCESTER, MASS.—The Stearns-Knight car agency has been taken over by the Worcester Motor Car Company which, with the Franklin, now has an excellent display of 1912 models.

DETROIT—The Ford Motor Company has announced that the company would build 75,000 cars for 1912. Besides the model T fitted with various body styles, the company will put out a new light delivery wagon.

HENDERSON, N. C.—The Corbitt Automobile Company, recently incorporated for $250,000, will take over the automobile department of the Corbitt Buggy Company. The company announces that the 1912 production will be about 500.

GRAND RAPIDS, WIS.—The Commercial Club, of Grand Rapids, Wis., practically has obtained sufficient subscriptions for stock in the proposed Crowe Motor Car Company, to make certain the establishment of the plant in this city.

WORCESTER, MASS.—The Atterbury Motor Truck Company, of Buffalo, has opened a branch in this city, at 735 Main street, where repairs will be made and where a large salesroom is now being fitted for a display of many models for commercial use.

MINNEAPOLIS, MINN.—Walter D. Rightmire, for several years associated with the automobile trade in Minneapolis, has opened a branch at Duluth, where he has secured the Iron Range as a territory for the Packard line. He has installed a service department.

INDIANAPOLIS, IND.—Dr. H. L. Lathrop has resigned as treasurer of the Henderson Motor Sales Company, Indianapolis, and has been succeeded by his son, H. C. Lathrop. O. W. Seymour and E. E. Kleinmeyer have just been added to the local sales department in Indianapolis.

DENVER—The Lozier Six, which was designated by the Denver Motor Club as the pathfinder for the Denver *Times* Reliability Contest, which the club will supervise October 9-14, returned to the city on Thursday, having completed its work of routing the tour. The route selected is 867 miles long.

NEW YORK—R. J. Laciar has been appointed general manager of the New York branch of the Hupp Corporation which has just leased the building at 1989 Broadway, formerly occupied by the Carhartt Sales Company. The entire building will be devoted to the display of the "R. C. H." automobiles and of the Hupp-Yeats electric cars.

WORCESTER, MASS.—Local business men with the cooperation of the Worcester Board of Trade are making determined efforts to have the United States Motor Company locate its proposed special factory, to manufacture parts of automobiles, in this city and to that end several excellent factory sites have been offered the concern.

MINNEAPOLIS, MINN.—Minneapolis is afforded an opportunity to secure a large automobile-parts manufacturing plant provided sufficient inducements are offered the United States Motor Company. B. E. Stimson, manager of the United States Motor Company, says that the concern is planning a large factory to be located in the Middle West at once and he suggests that this city make an effort to have it placed here.

Automobile Incorporations

AUTOMOBILES AND PARTS

ALBANY, N. Y.—Tri City Motor Company; to deal in automobiles.

ALEXANDRIA, VA.—The B. F. Board Motor Truck Co.; capital, $100,000.

CHARLESTOWN, S. C.—The Robinson Automobile Co.; capital, $10,000. Incorporators: J. T. Robinson and B. F. Robinson.

COLUMBIA, S. C.—The Gregory-Conder Motor Co.; capital, $20,000.

DALLAS, TEXAS.—Overland Automobile Co.; capital, $25,000; to handle automobiles. Incorporators: W. W. Taxis, D. T. Finley and F. M. Bannell.

EL PASO, TEXAS.—Rio Grande Automobile Co.; capital, $5,000. Incorporators: Max Moye, W. F. Carter, Jr., and John M. Wyatt.

LAFAYETTE, IND.—Ross Machine Co.; capital, $15,000; to manufacture automobile parts. Incorporators: David E. Williams, C. Linn and Edward A. Ross.

NEWARK, N. J.—Blair Manufacturing Co.; capital, $300,000; to build automobiles. Incorporators: Frank M. Blair, John R. McCune, Willis A. Robbins, Edwin C. Wright and Harry H. Baird.

AUTOMOBILE GARAGES AND ACCESSORIES, ETC.

CAMDEN, N. J.—American Roller Bearing Co.; capital, $500,000; to manufacture roller bearings. Incorporators: V. A. Murray, L. A. Myers and D. Bellinger.

COLUMBUS, OHIO.—Borland Manufacturing Co.; capital, $150,000; to manufacture automobile wheels, automatic pipe wrenches and other tools. Incorporators: J. Archer Borland, G. W. Borland, G. A. Hoffelder, E. W. Habermass, H. L. Hogan and Otto Klein.

MEMPHIS, TENN.—The Ozburn Automobile Supply Co.; capital, $15,000. Incorporators: N. F. Ozburn, W. J. Shay and W. P. Armstrong.

NEW YORK, N. Y.—Higrade Auto Tire Sales Co.; capital, $50,000; to manufacture and deal in tires. Incorporators: A. Foshay, H. Neubardt and R. Goldman.

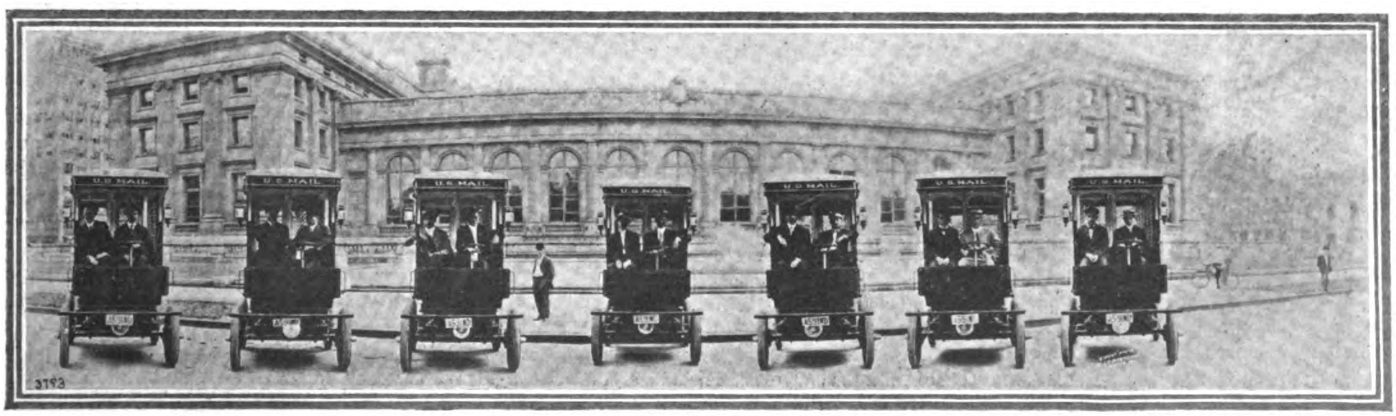
NEW YORK, N. Y.—Senora Motor Horn Co.; capital, $50,000; to manufacture automobile signals and supplies. Incorporators: Russel Goldman, A. Foshay and Helen Neubardt.

NEW YORK, N. Y.—The Griffins Automobile Supply Co.; capital, $100,000; to handle automobile supplies, etc. Incorporators: Carl S. Brown, Frederick Kopper, Jr., and Thomas H. Griffins.

PADUCAH, KY.—Kentucky Auto & Machine Co.; capital, $5,000; to deal in automobile supplies. Incorporators: F. M. Fisher, R. G. Fisher and W. F. Paxton.

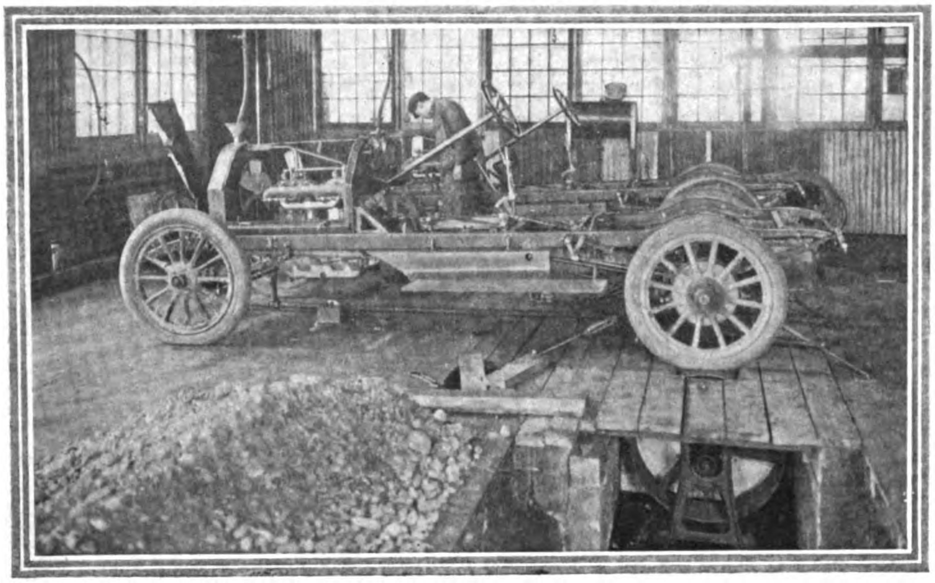
SHAWANO, WIS.—Frognor Auto Co.; capital, $5,000; to handle a garage.

SPRINGFIELD, ILL.—Reliable Tire Repair Co.; capital $2,400; tire repairing. Incorporators: John V. Leslie, George Haas and Bert A. Fritz.



Battery of seven United States mail wagons delivered by the Waverley Company for use in the Post Office service in St. Louis

OF INTEREST to the INDUSTRY



DAYTON, O.—In the testing department of the Speedwell factory the bearings were formerly run in by raising the rear wheels on a revolving drum. The motor is started and the gears engaged so that the rear wheels revolve on the drum—a brake on the latter providing friction equivalent to that of the road surface. An improvement has recently been effected by lifting the rear axle so that the wheels stand clear of the floor. Then the live split rear axles are drawn out, and axles with sprockets substituted. Coupling the sprockets by chain drive to a shaft provided with sprockets and brake, the same result is accomplished without tire wear. This method of testing suggests that a farmer, by the use of a similar contrivance could use his motor car to furnish power for pumping and running various farm machinery when the car is not in use on the road.

DETROIT—The T. Eaton Company recently completed negotiations with the Lozier Motor Company for the sales rights of the Lozier in Ontario.

OIL CITY, PA.—E. M. Bowen and G. C. McClelland have opened the West End Garage at Oil City in the fireproof building Front and Moran streets.

SYRACUSE, N. Y.—W. E. Hookway has taken over the agency for Atterbury trucks, 1,500-pound delivery wagons and 1-ton trucks, along with the Reliance line of heavy trucks.

SYRACUSE, N. Y.—J. E. Bristol, of the United Motor Syracuse Company, who has just finished a successful tour of Northern New York in the interest of the Maxwell runabout, reports that he now has also the agency for the Samson motor truck.

SYRACUSE, N. Y.—E. F. Chaskel, formerly in the automobile business in New York, has established himself with the National Motor Sales Company, of this city, and will exploit National cars in this section.

SEATTLE—Hugh A. Baird, manager of the Franklin Automobile Company, of this city, has organized a selling agency which is known as Hugh A. Baird & Co. In addition to handling the Franklin product, he will act as agent for Reo touring cars, runabouts and trucks, and the Apperson line.

BUFFALO, N. Y.—The Lippard-Steward Motor Car Company, of Buffalo, has just secured the large and well-located plant formerly occupied by the Thomas Taxi-Cab Company, moving into the new quarters October 1. The company will manufacture 1,500-pound capacity delivery motor trucks, police patrols, ambulances, chemical fire wagons, etc.

NEW YORK CITY—E. Louis Kuhns, long manager of the motor car department of the Chicago Studebaker branch, has been transferred to eastern territory and last Monday he assumed the management of the New York Studebaker branch. Temporarily Lafayette Markle, special factory representative, is in charge of the Chicago branch, while H. E. Westerdale is looking after the retail business.

SAN FRANCISCO—The largest and most elaborate automobile building in San Francisco has just been occupied by the H. O. Harrison Company, distributers of Peerless and Everitt cars in California. The building is said to be one of the largest in the United States devoted exclusively to automobile purposes. The building is four stories on the east end and three stories on the principal frontage on Van Ness avenue.

SAN FRANCISCO, Sept. 26—The Speedwell Motor Car Company, of California, has moved to new and larger quarters at 422-428 Van Ness avenue. This move affords a larger showroom, and there is a good-sized workshop in the rear. L. V. Lynch, president and manager of the company, came here from the East two years ago, and is now recognized as one of the most aggressive men in the California field.

SAN FRANCISCO—Bert S. Bingham, Pacific Coast representative of the Regal Motor Car Company, of Detroit, has been appointed manager of the eastern district of that company, with headquarters in New York City. He will be in charge of the warehouses in that territory. He has already left for his new field. Bingham established the Regal branch in San Francisco two years ago, and since the abolition of the branch in favor of a private agent, he has been general coast representative of the company.

SAN FRANCISCO—The Standard Motor Car Company, the newly appointed coast distributers of Division B of the United States Motor Company, comprising the Stoddard-Dayton and the Courier lines, is preparing to make a considerable enlargement of its quarters at the corner of Golden Gate and Van Ness avenues, which marks the center of the automobile retailing district of the city. The Standard has a lease of the entire building, and it is probable that some of the other firms will be obliged to find new quarters so that the Standard may expand.

SYRACUSE, N. Y.—The R. N. Tannahill Company, of Greenville, S. C., has signed up the Franklin dealership for that locality, succeeding C. M. Wing. J. W. Vernam, of New Kensington, Pa., has contracted with the Franklin Automobile Company as a subdealer in the Pittsburg district. Charles Wirth, of Terre Haute, Ind., has been made salesman by the Terre Haute Automobile Company, the Franklin dealer in that town. The Franklin Automobile Company is to be represented the coming season in the southern half of Texas by the Franklin Motor Car Company, of Houston.

SAN FRANCISCO—The Apperson car is now represented in San Francisco and throughout Northern California by the Weeks-Covell Automobile Company, who will also handle the Pathfinder and Parry cars in this territory. W. H. Weeks, a San Francisco architect, is president of the newly organized company, with J. H. Covell, a successful garage man of Watsonville, as vice-president and manager. Russell Cuthbert has been appointed sales manager. Temporary quarters have been secured at 550 Golden Gate avenue.

PATENTS GONE TO ISSUE

FRICTION CLUTCH—Being of the multiple-cone type.

The clutch covered by this patent and shown in Fig. 1 comprises a number of driving and driven members with opposing surfaces, frictionally engaging segments being interposed between the surfaces and arranged one in advance of the other in a ring-shaped series substantially concentric with the surfaces mentioned. A portion of each segment is fixed to one surface, and springs are provided between each segment and the surface it is connected to, which springs normally hold surface and segment out of frictional engagement. Means are also provided whereby the members may be moved axially toward one another to bring about engagement of the frictioning members.

No. 1,004,047—to Willard C. Lipe, Syracuse, N. Y. Granted September 26, 1911; filed December 7, 1905.

WHISTLE—Being of the type driven by an electric motor.

1. The whistle this patent relates to consists of a waterproof casing with an opening therein, an air pump mounted in the opening, an outwardly projecting whistle forming the pump outlet. Within the casing a rotary motor is mounted which is connected to the pump by gearing.

No. 1,004,337—to George F. Atwood, New York City, assignor to Western Electric Co., Chicago, Ill. Granted September 26, 1911; filed October 25, 1907.

GEARSHIFT LOCK—A plate for locking change-speed lever in neutral position.

The lock (Fig. 2) comprises an H-plate, a lever adjustably guided by the plate, which includes means for holding the lever in neutral position, a member being removably fitted to the H-plate and embracing a portion of the lever and operating to hold the lever against movement on the H-plate. The member mentioned has spaced walls with a recess therein and the opposite wall has a bolt-receiving passage. A second member is removably fitted to the first member and provided with a lug removably fitting the recess in the first member, and it also carries a bolt adapted for locking engagement in the aforesaid passage to hold the first and second member connected with each other.

No. 1,004,396—to David H. Evans, Detroit, Mich. Granted September 26, 1911; filed March 7, 1911.

ENGINE STARTER—Consisting of a ratchet and pawl.

The starter this patent refers to (Fig. 3) consists of a combination with a ratchet wheel having a hub fixed to the end of the engine shaft, of a drum surrounding that wheel and loosely embracing its hub and having a hole in line with the shaft mentioned. A wide pawl is pivoted within the drum and normally pressed into engagement with the ratchet by a spring. Means are provided to direct the rotation of the drum in one direction, as well as retracting means for rotating it in the opposite direction. A bracket is secured to the automobile frame, projects fixedly and axially through the hole in the drum, and a finger rises rigidly from the bracket within the drum between the latter and the wheel. The tip of this finger constitutes a cam upon which the pawl rides as the drum returns to its retracted position.

No. 1,004,508—to Ernest N. Ward, Baxter Springs, Kan., assignor of one-half to Jay F. Ripley, Joplin, Mo. Granted September 26, 1911; filed January 5, 1911.

SPARK PLUG—Being of the make-and-break type for low-tension ignition systems.

1. The plug (Fig. 4) has among its elements an electromagnetic coil having a core which is provided with a semi-cylindrical recess with a flat face. From this face a series of studs project, being arranged longitudinally and eccentrically of the core. In the recess mentioned fits loosely a semi-cylindrical armature having an inner face which is provided with a series of recesses, loosely receding studs, whereby the armature may be rocked to and from the core. A movable contact carried by the armature is connected therewith, and a stationary contact is provided which is contacted by the movable contact when the armature is in the outward position, means being provided to hold the armature in that position.

No. 1,004,325—to Max Wild, Stuttgart, Germany. Granted September 26, 1911; filed November 6, 1908.

PNEUMATIC TIRE—Consisting of a special cover and lining.

1. In combination with a wheel rim and a tire cover held thereto, an air tube within said cover, a lining between said cover and the air tube, having an inextensible crown which is recessed in proximity to the tread and adapted to holding the outer cover distended and to take up the vibrations of the running jars while being guarded by said crown against excessive air pressure from the air tube substantially as set forth.

No. 1,004,343—to John Charles Barker, Leeds, England. Granted September 26, 1911; filed May 7, 1910.

COMBINED VALVE AND TRAP—Consisting of a valve with a partition which forms a baffle plate to trap moisture.

A valve casing having an inlet and an outlet, a partition in said casing, a trap extending downward from said casing, one side of trap communicating with said inlet and the other side thereof communicating with the outlet.

No. 1,004,239—to Wm. Brunton, Elwyn, Pa. Granted September 26, 1911: filed October 22, 1911.

Newest Ideas Among the Accessories

Prest-O-Tire Tube

THE Prest-O-Tire tube shown in Figs. 3, 4 and 5 has been constructed with the object of pumping up a tire in the minimum space of time and with the least effort. Fig. 4 shows the external view of the tube in its application to a tire. The tube is made of a piece of steel 1 foot long, and at its upper end is closed by a copper plate fully strong enough to withstand the 900 pounds pressure of the carbonic acid gas enclosed in the tube. Fig. 3 shows the handle H_1 screwed off the tank; it contains a passageway for the gas and a needle N_1, which when screwed down cuts a hole in the copper plate shown at C_1 Fig. 5). The punctured plate is seen at P_1. If the needle valve is opened by turning the handle, the gas is allowed to escape through the passageway which is connected up to a flexible tube F_1 and this in turn to the tire valve. When the tire is inflated to the desired degree the handle is turned so as to close the valve and shut off the gas.

The section of the working parts is seen in Fig. 5, and the component parts are also shown. The seating S_2 of the needle valve is bored through the copper plate C_1 and so arranged that lifting the needle makes a free way for the carbon dioxide. The valve casing C_3 is bored to permit of a passage for the gas which rises around the needle N_1 and escapes through O_1. The needle is fastened to the body of the valve spindle S_1, which is threaded at P_2 to engage with the threaded inside of the casing. The upper part of the spindle is supported by a bushing B_1 and the handle H_1 serves to operate the needle.

At a test made with the tube a 36 x 3 1-2 tire was inflated from 0 to 90 pounds within 1 minute and 32 seconds. The tube is the product of the Prest-O-Lite Company, Indianapolis, Ind. First cost of the tank is low and after the contents have been used for inflating purposes, it is exchanged for a full tank for a very small sum.

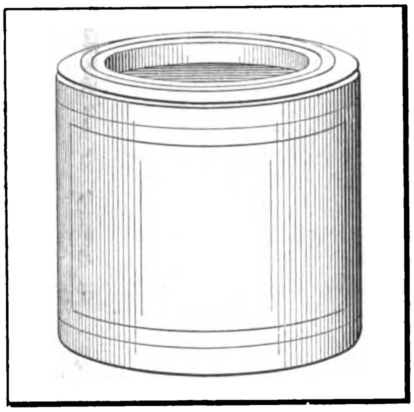

Fig. 1—Goodyear quick repair gum

Goodyear Repair Gum

The Goodyear Quick Repair Gum comes in tins, as shown in Fig. 1, and its purpose is the repair of cuts in outer tire casings as well as in inner tubes. In either case the simple process of repairing the damage consists of two steps. After washing the wound with gasoline it is coated with Goodyear patching cement, two coats being necessary to prepare the tube or casing for the subsequent treatment with the repair gum. After the second cement coat has dried, a sufficiently large piece of the repair gum is kneaded with the fingers until it becomes very soft; then it is applied to the wound, taking care that the latter is filled completely and that the gum adheres to the cement at all portions of the wound. This repair gum is manufactured by the Goodyear Tire & Rubber Co., Akron, Ohio.

Doyle Signal Light

In Fig. 2 is shown a combination of a tail lamp, license number and direction signal, the accessory illustrated being Doyle's warning signal light. It is a small metal box containing four incandescent lamps which may be lighted singly or in unison from a little switchboard attached to the steering wheel. The lights are placed behind perforations reading as in Fig. 2, and by turning on any of the upper three lights, the chauffeur may inform the driver of the car behind of his intention of turning into the next street to the right or left, as the case may be, or of stopping, advising his follower to slow down. The usual manner of giving these signals is by a motion of the arm, which is hardly visible at night, so that some method of illumination is necessary. The lower part of the signal box contains a pocket for a number plate, which may be removed therefrom at will, and a red jewel throwing enough light on the number to make it legible. The lamps in the top row, being used only occasionally, require very little current. The selling office of the maker is at 1777 Broadway, New York City.

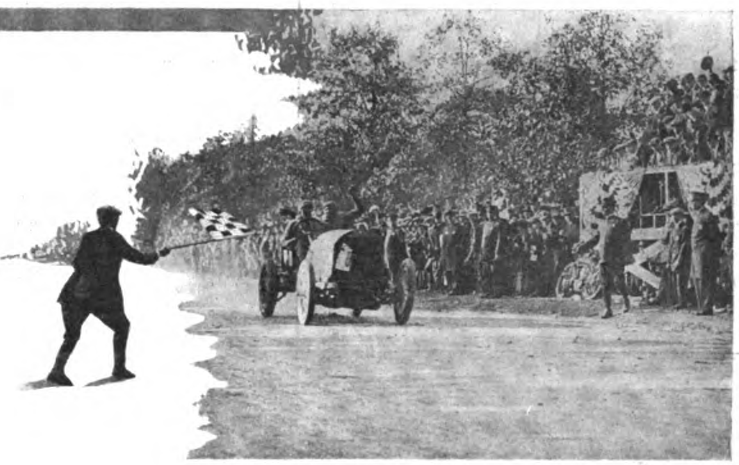
VOL. XXV. NEW YORK—THURSDAY, OCTOBER 12, 1911—CHICAGO No. 15

THE AUTOMOBILE

Bergdoll in Benz, Fairmount Winner



Erwin Bergdoll, Driver of the Big Benz Car Which Won the Fairmount Park Race and Established New Lap and Race Records

The Winning Bergdoll-Benz Combination Being Given the Checkered Flag by Starter Gantert

PHILADELPHIA, PA., Oct. 9.—Leading practically all the way, Benz No. 8, driven by the boyish millionaire, Erwin Bergdoll, won the sweepstakes and the class 6C prize over the Faimount Park course today. The Benz broke the record for the classic; raised the level of average speed to 61.25 miles an hour; lowered the lap mark to 7:28 and cleaned up all around.

Mercedes, No. 17, driven by Spencer Wishart, the same car that raced into a forward position in the 500-mile sweepstakes at Indianapolis on Decoration Day, finished second in the general race and first in its class, flashing past the finish line 1:41 ahead of Lozier No. 3, Ralph Mulford's mount. The Mercedes was protested immediately after the finish for failing to carry its crew throughout and the protest was allowed.

National 16, Disbrow, won the Class 4C division from the consistent-running Stutz, piloted by Anderson.

In Class 3C, the only car to complete the full course was Mercer No. 11, Hughes, which made the distance in 209:45.30. When the race was called off, the Ohio pair were still jogging around, No. 12 having completed twenty laps and No. 19 having finished twenty-two rounds of the 8 1-10 mile course.

The course was not in the best condition, having dried

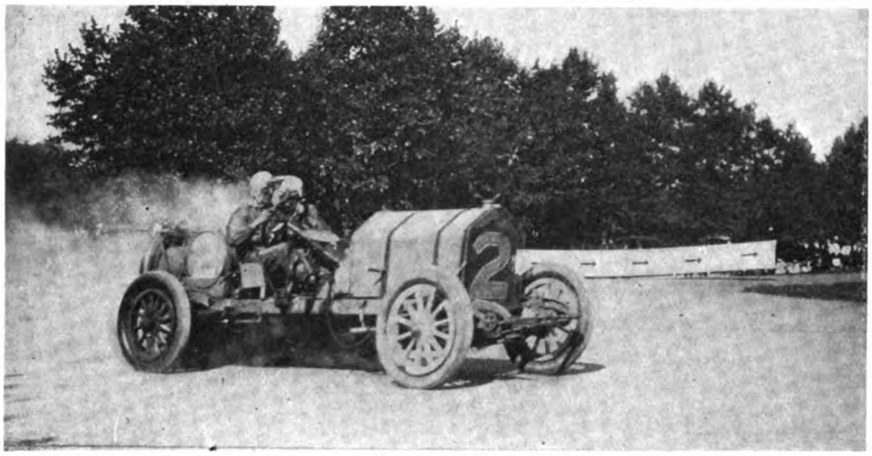
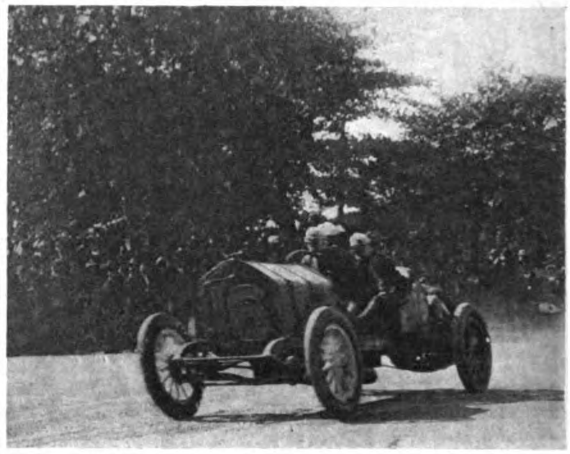
DIVISION 3C.

No. 11. **Mercer.**
Hughes driver.
Time, 3:29:45.30.



National No. 2, driven by Zengel, who won last year's race in a Chadwick



Disbrow National, No. 16, winner in its class

out on top to such an extent that the racing cars threw up dense dust clouds in making the turns. The fast time accomplished was due to the improvement in the automobiles themselves rather than to course conditions.

The crowd was rather slow in assembling, but just before noon the seat-holders in the grandstands poured in and when Starter G. Hilton Gantert lined up the contestants, there was scarcely a vacant seat. All around the course the crowds assembled to witness the speed struggle and while the total number of those who witnessed the race was much below that of last year, it is estimated that at least 350,000 saw the triumph of the Philadelphia-owned car.

The cars were arranged in two lines, the even numbers on the pole and the odds on the rail and the heads of the columns were sent away at 20-second intervals. F. E. Edwards, chairman of the Technical Committee of the Contest Board, stood at Starter Gantert's elbow throughout this important function. The start was very perfect.

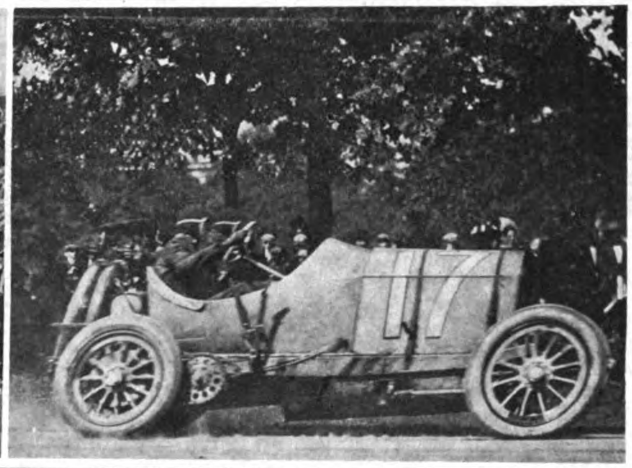
Mulford's Lozier, finishing second in its class



Wishart's Mercedes, which was disqualified for losing its mechanician

National No. 2, Zengel, was first away, followed by Lozier No. 3, Mulford; then came the Cole No. 4, Basle, and Mercer No. 5, De Palma, and so on to the end of the line, which was occupied by Ohio No. 19, Matthews.

National No. 2 was the first to appear at the head of the stretch on the initial round and came down to the wire wide open in 7:51, widening the distance between it and the pursuing Lozier by 4 seconds on this circuit.

But neither of these cars was destined to enjoy a leading position for the round, or in fact at any time during the race, as the giant Benz No. 8 came down to the line in 7:34, lowering the lap record for the course by 4 seconds, even though the standing start would seem to have interposed an insurmountable obstacle to record breaking. That first swift round foreshadowed the ultimate result of the race, for it was a foregone conclusion after the time was posted that, barring accidents, there was nothing that could catch the flying leader.

During the preliminary practice the speed of this car was

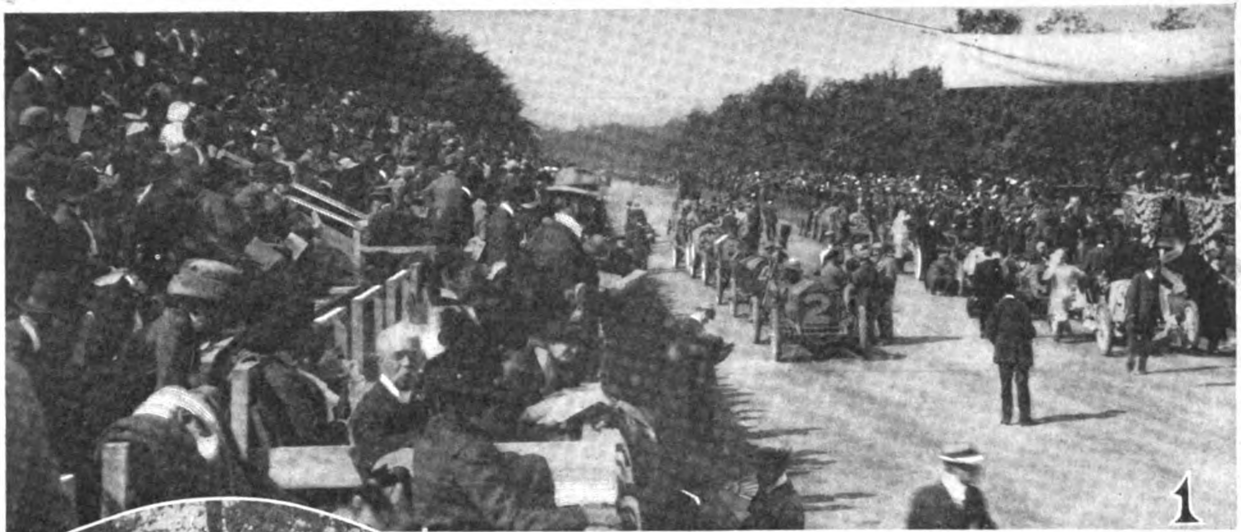
SCENES AT THE FAIRMOUNT PARK RACE

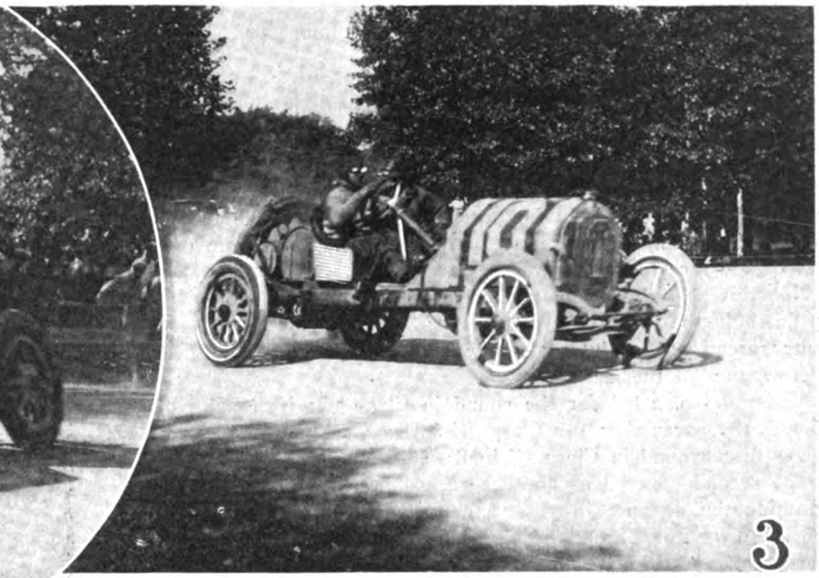
1. Despite the postponement of the race from the previous Saturday, the stands and course were crowded. The illustration shows the excellent manner in which the course was guarded.

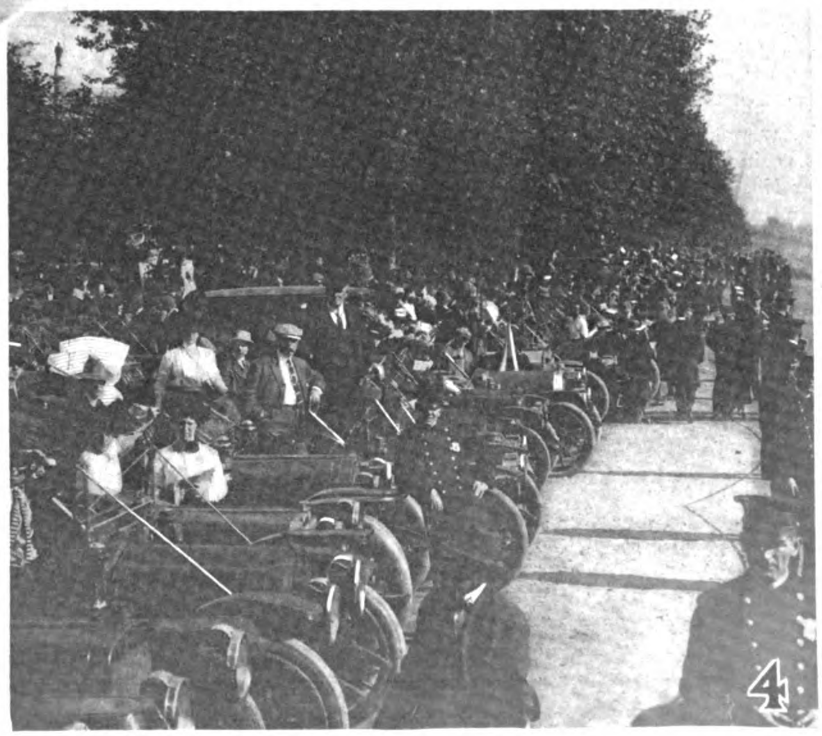
2. Ohio car, No. 12, driven by George Parker, which was still running at the conclusion of the race.

3. The Lozier-Mulford combination was a favorite with the crowds—the car is shown passing the grandstand at 70 miles an hour.

4. The accommodations for the 200 pressmen were thorough in every detail, and reflected great credit on the management.







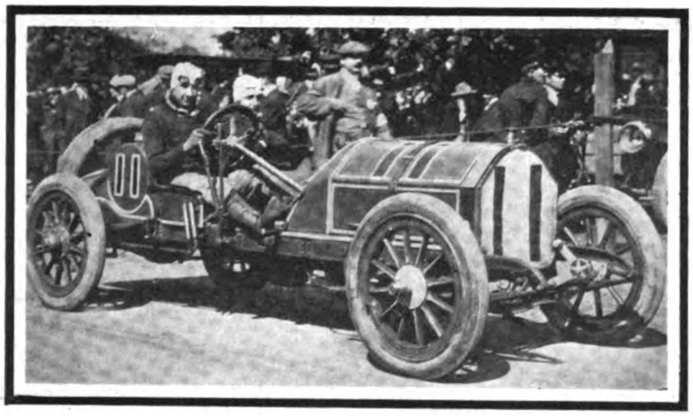
SCENES AT THE FAIRMOUNT PARK RACE

1. In lining up the cars at the start the machines were arranged in two lines, even numbers on the pole, odd numbers on the rail.

2. The winning Benz, with Bergdoll at the wheel, was caught at close quarters by The Automobile staff photographer while the outfit was traveling close to 75 miles an hour.

3. The Stutz entry, No. 10, with Gil Anderson at the wheel, performed creditably throughout the race.

4. The thousands of cars were parked well back from the course, with a strong cordon of police between them and the road.



The Hughes Mercer, which ran consistently and captured 3C honors

specially noted by the contesting drivers and their attitude is best expressed by the sentiment spoken by Mulford before the race in conversing with Zengel:

"Have you passed that big Benz?" inquired Zengel, speaking of the preliminary practice.

"No," replied Mulford, "I haven't passed him, but I have seen him go by."

"Who was that driving the car last Thursday?" asked Zengel.

"Durned if I know," came the answer, "he drove like Hemery."

And that is the whole story.

From the moment Benz No. 8 showed in front at the end of the first lap, with an advantage of 17 seconds over the second car, it was a battle merely for position in the classes. But they made a gallant fight and kept shooting at the big car from one end of the race to the other.

Nobody experienced any trouble in the first round, Ohio No. 19 finishing the lap in last place in 9:58 with the other contestants spread out at intervals between that time and the fast performance of the leader.

National No. 2 led for the round in Class 5C; National No. 16 was the pacemaker for Class 4C in 8:30, while Mercer No. 5 was first around in Class 3C in 8:20.

The second round was another record breaker, the Benz negotiating the distance in 7:28, a new course mark, with Mercedes No. 17 and National No. 2 tied for second honors. National No. 16 still led its class, but in 3C Mercer No. 11 displaced its teammate and showed in front at the tape. There were no mishaps in this round, everybody finishing without untoward incident.

For the following fourteen laps the Benz stayed out in front, moderating its extreme speed in order to save tires. Mercedes No. 17 was second for the next half-dozen rounds, maintaining its position about 2 minutes behind Bergdoll's mount, with Lozier No. 3 in third place, a few seconds back.

In round ten, however, the Lozier went ahead of the Mercedes and began a long stern chase after the leader. For the next six laps the Lozier stayed in second place without cutting down the gap materially.

In the seventeenth round both the Benz and the Lozier stopped for tire changes and the Mercedes, which was only a few seconds behind the white car, moved up into pacemaker's position.

Bergdoll did not essay to wrest the lead away from the Mercedes in one round, but he kept cutting down the seconds for three laps and at the end of the twentieth lap the black car was again setting the pace.

Mercedes experienced trouble in round twenty-two and the Lozer stepped up into second place again, only to succumb to a pair of blown tires in the following lap.

The final round and the finish were not spectacular. Everybody knew that the Benz would win unless it broke an axle and it fulfilled its owner's expectations by making the last lap in 7:38.35, winning rather easily, although by only a moderate margin, in 198:41.35. This is faster than the record-breaking performance of Chadwick last year by more than 10 minutes, which would represent 1¼ laps run in reasonably fast racing time.

The Mercedes finished second in 200:11.42, which is in excess of a mile-a-minute gait, but was disqualified for an unusual occurrence during mid-race. Wishart was going fast down the Sweetbriar incline and when he turned into the straightaway, just before passing Penn mansion, Bob Willoughby, his mechanic, was unseated by the swerve of the car and fell out upon the roadway. Willoughby rolled out of the course of the racing cars and Wishart, not to be delayed for a second at that important stage of the race, went on without him. He picked up another helper at the pits and finished the race as has been told. Willoughby was not seriously hurt.

Under the rules a contesting car in such a race as the Fairmount Park must carry a driver and mechanic from start to finish and when formal protest was lodged with Referee Dunlap, on behalf of the Lozier company, the official promptly allowed the protest, disqualified the Mercedes and gave the place to Lozier No. 3.

The matter in all probability will be presented to the Contest Board for revision.

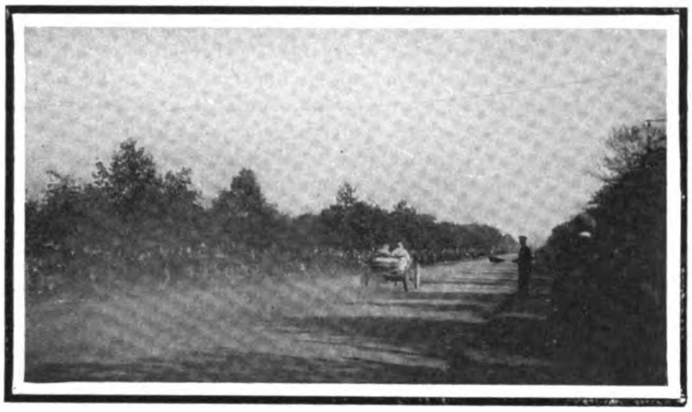
Mercer driven by Hughes, which was the only car in its class to finish the race—the Mercer has just passed the Cole



Looking down the stretch toward the first turn at the top of Sweetbrier Hill

There was virtually no contest in division 6C. Originally three entries were made for this class, including two Fiats of 90-horsepower and the Benz rated at the same power. Fiat No. 1 was scratched after disapproval had been expressed as to the good taste of starting Lee Oldfield as its driver. This left the Bergdoll Benz and the Betz Fiat to fight it out in the big class. The Fiat made two fast rounds, being only 39 seconds behind its rival at the end of the second circuit. But during the third lap a broken connecting rod caused it to limp up to the grandstand and withdraw. Mr. Betz has experienced similar misfortune. Last year his mount broke a crankshaft while well up with the leaders and he was obliged to watch the race from the stand just as he did to-day.

The prettiest struggle of the race was in division 5C, in which there were five starters. These included a special National, rated at 50-horsepower and driven by Len Zengel, who drove last year's winner, a 6-cylinder Chadwick; a pair of Loziers, driven by Mulford, who piloted the second car last year, and Grant, who was at the wheel of the Alco entry which won two Vanderbilt cup races; and a pair of Mercedes cars, rated at 90-horsepower, driven respectively by Spencer Wishart, son of the New York millionaire banker, and Wallace.

The National was only prominent for two rounds when tire troubles intervened and gave it a handicap that could not be overcome. Three different times during the race this car had to stop for tire changes and each stop occurred at a time when it might have had a chance to displace some of the leaders. It was second in the race and first in its class at the end of the first round, but fell back to third place in the next lap. Then came the tire trouble, which was aggravated by its coming about 2 miles from the pits, causing Zengel to drive slowly for that distance and this delay, together with the time spent in making the change, lost something like 5 minutes for the car.

For fourteen rounds the car went along smartly and was within striking distance in round eighteen, when the tires went bad again and the car was laid under still more handicap. Round twenty found it in trouble again, but Zengel finished smartly in 205:59.36, making the last lap in 7:45.

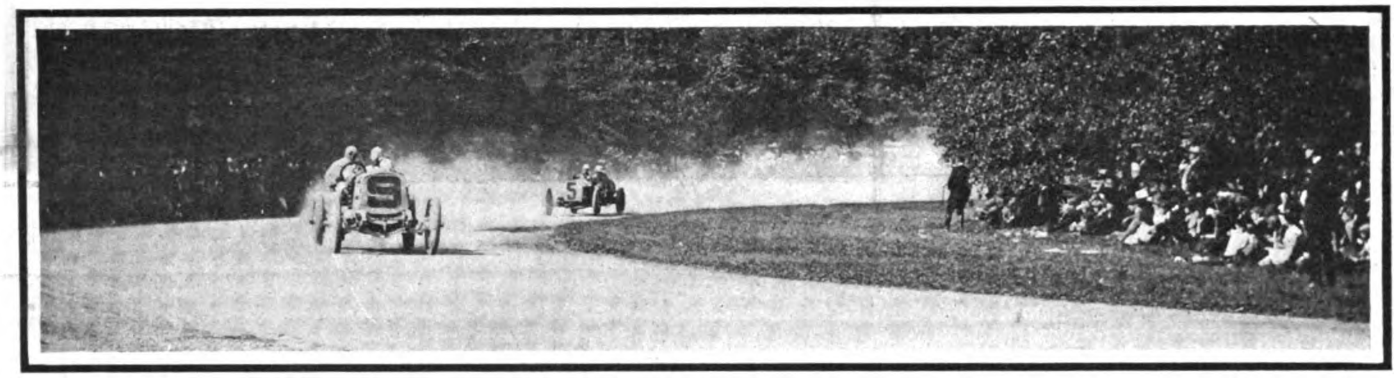
Lozier No. 3, Mulford, ran a brilliant and consistent race. The car started at moderate speed and was not placed until three laps had been made. Mulford maintained an average speed of 7:50 per lap for the first twenty rounds. Two rounds during mid-race were run on weakened tires, but the pilot kept going smartly until the Benz waved the distress signal, when both cars went to the pits. Mulford's crew outdistanced the repairmen of the Philadelphia car in making the change and when the pair returned to the contest, the Lozier actually had gained over 1 minute on its rival. This, however, did not serve to improve its position, as the Mercedes had taken full advantage of the tire trouble to dart into the lead, leaving the Lozier in third place. In round twenty-three the real, heart-breaking mishap occurred from the Lozier viewpoint, as Mulford was again obliged to change tires, dropping back to third place after having wrested second position from the Mercedes in the preceding round. The last laps were negotiated in about 7:40 each, which was not fast enough to get the money.

With regard to the protest filed by Mulford and sustained by Referee Dunlap, the situation developed that if Wishart had stopped to pick up his mechanic, the chances are that the Lozier would have beaten the German car. Of course there is no way to determine just how much strain was removed from tires and mechanism of the Mercedes during the partial round in which it did not carry its full load, but racing experience proves that it amounted to something.

Lozier No. 9, Grant, experienced tire trouble frequently at all stages. In spots this car was estimated to be making 90 miles an hour, which may account for the tire trouble. The car had sparkling speed throughout, but finished over 10 minutes behind the Benz.

Mercedes No. 17, Wishart, had clear sailing all the way. The car made only one slow round, lap twenty-two, when tires were changed, making the time for the round 11:14. It was among the first three from start to finish and in lap eighteen looked to have a strong chance to beat out Bergdoll's Benz. From there to the end, however, it faded out a trifle and after the mishap to its mechanic, was not so sharply driven as in the earlier

After the race hundreds of thousands of spectators flocked over the course



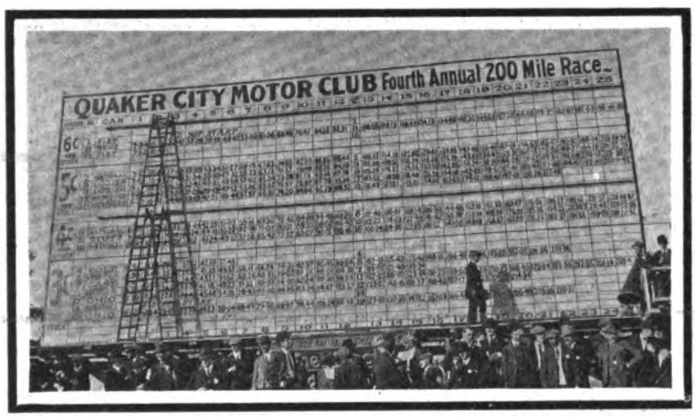
Grant's Lozier leading De Palma's Mercer on the Neill Drive turn—note way crowds were kept back from the course

stages. Its final time was 200:11.42, which is considered faster than the time of previous winners of the classic.

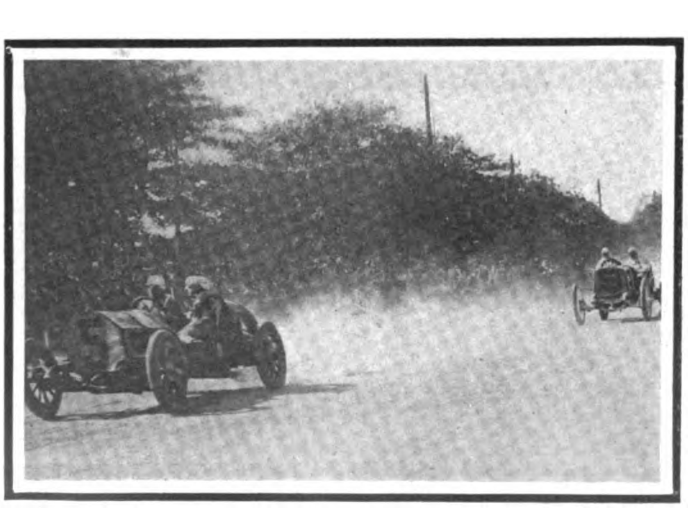
Mercedes No. 18, Wallace, experienced tire troubles and ran through the last ten laps with its engine making signals of distress. No formal reason was given for its poor showing, but it was surmised that either ignition or carbureter was at fault. The car was running at the end but only completed twenty-two laps.

In Division 4C there were three starters, a pair of Nationals and a Stutz. National No. 16, Disbrow, jumped away in the lead and was first at the end of each lap to the finish. The car ran smoothly throughout and gradually increased its lead to the end.

At no time during the race did it make any prominent bid for the general sweepstakes, but it dashed along with a beautiful certainty under the skilled hand of its pilot. Its time was 208:22.32, just under 60 miles an hour on the general average.



The Quaker City Timers' Club had the scoreboard situation well in hand



Grant's Lozier overtaking Mercer No. 5 at the head of the stretch

and ahead of the winner of the general sweepstakes of last year.

Stutz No. 10, Anderson, ran an impressive race, never seriously threatening Disbrow's mount, but always shooting at the winner on the long stretches of the course. The Stutz did not have a moment of mechanical trouble and no tire trouble to speak of. It was well handled and its showing attracted a vast amount of attention. It lay in third position in the class until lap 24, when it forged ahead into second place and so it finished. The time of the Stutz was 220:23.05.

National No. 6, Herr, car and driver the same that won the Illinois Cup at Elgin, finished third. Herr followed Disbrow rather closely for twenty-three laps and looked to be surely entitled to second place in the class when a bad tire change caused him to make a slow circuit in round twenty-four and the Stutz displaced him. There was a thrilling duel between National No. 6 and the Stutz in the last rounds, but Anderson had an advantage of 10 seconds in round twenty-four and maintained it to the wire.

Division 3C had seven entries including Cole No. 4, Basle; Mercer No. 5, De Palma; Case No. 7, Jagersberger; Mercer No. 11, Hughes; Ohio No. 12, Parker; Bergdoll No. 14, G. Bergdoll, and Ohio No. 19, Matthews. Bergdoll No. 14 was scratched before the start and the other six formed the field.

Mercer No. 11, Hughes, won all the way and finished all alone in the class. This car was second at the end of round one, being 1 second behind De Palma's Mercer at that stage. But from the second round to the end, Mercer No. 11 stayed out in front. It had no troubles of any kind and simply sailed along at a gait that rivalled the Chadwick's time in 1910. The Chadwick is a Class 6C car, with more than twice the piston displacement of the Mercer. The final time of this car was 209:45.30.

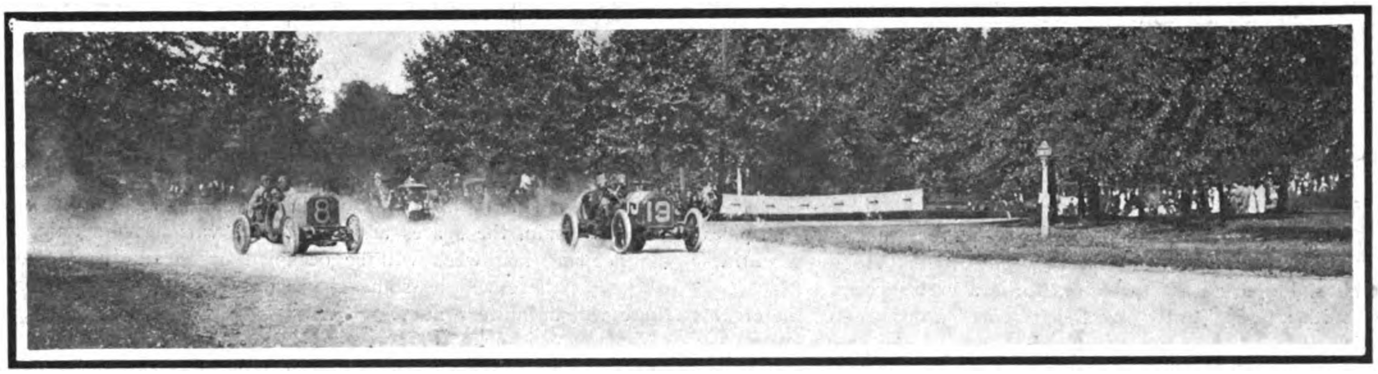
Ohio No. 19, Matthews, was second, finishing twenty-two rounds before the race was stopped. Mercer made a creditable showing from the viewpoints of reliability and speed, but did not show enough of the latter quality to develop anything like a struggle in this class.

Ohio No. 12, Parker, completed twenty laps before the checkered flag announced the finish. It had three very slow rounds, the result of tire trouble far from the pits or stations, but was running well at the finish.

Cole No. 4, Basle, finished six laps at moderate speed when carbureter troubles developed and the car retired from the contest.

Mercer No. 5, De Palma, looked like the winner of second place in this class for twenty-two rounds, when a broken steering knuckle caused its retirement. The mishap occurred in front of the stands at the end of round twenty-two and the driver wriggled the disabled car over against the stand after passing the line. For the first fifteen laps this car was only a few seconds behind its teammate, but beginning with that round it fell back until the final mishap put it out of the running.

Case No. 7, Jagersberger, finished thirteen laps at fair speed and was not completely out of the race when it became unmanageable on Sweetbriar hill and, skidding, struck a post. This



The Bergdoll Benz passing Ohio, No. 19, on the turn around the base of George's Hill

resulted in a broken spring and called for the retirement of the car.

Of the sixteen starters in the race, nine finished and three were running when the final flag was dipped.

The race was the fourth annual event staged at Fairmount Park under the auspices of the Quaker City Motor Club. It was originally scheduled to be held on Saturday, October 7, but a wet and slippery course caused the race to be postponed until Monday. Under the conditions, the event was divided into four classes, coming within the limits of Class C.

To each division winner a prize of $1000 will be paid and to the Benz driver goes the sweepstakes prize of $2500. In addition to these purses there were the usual number of accessory prizes of various descriptions, the whole amounting to not far from $10,000.

The subscription for entry was fixed at $500 per car and as there was eighteen cars entered, the proceeds of entry amounted to $9000. The purses given by the club amounted to $6500.

While the crowd was not nearly as great as in other years, the stands were well filled and it was estimated that the receipts would be about $10,000 net, after deducting expenses. Under the conditions by which the City of Philadelphia patrols and polices the course, the net receipts from the sale of seats and privileges goes to organized charity.

The field for this year's race was small in comparison with that of 1910, when thirty-two cars started, and consequently the revenue of the club was much abbreviated. This was the result of several factors, one of the chief being the dispute that arose over the question of who should start the race.

After several heated colloquies with the A. A. A., in which ultimatums were passed to and fro, the original choice of the club, G. Hilton Gantert, was selected to officiate once more.

This decision was reached at a meeting of the full membership of the club, at which a vote was taken to instruct the directors to maintain Mr. Gantert in the position of starter at all hazards, even going so far as to promise financial aid to the extent of $20,000 in order to fight the case in the courts if the necessity arose for such action.

It was charged that the other candidate, Fred J. Wagner, had not supported the race this year or in other years. A letter was received by the club from the Contest Board outlining the necessity of having a man of national reputation handle the flags at the race and pointing out the disadvantages under which an incompetent man would work. This was construed by the club as supporting Wagner's claims and discounting those of Gantert and was considered an ultimatum, as the letter contained a clause cautioning the club to accept the services of the man with the national reputation or suffer the revocation of its sanction.

Robert P. Hooper, president of the A. A. A., was present at the meeting and immediately communicated with national headquarters urging some modification of the terms of the ultimatum. About this time Mr. Wagner withdrew from the contest in the interest of harmony and Mr. Gantert got the job.

The race itself was very successful from every point of view. It was truly run, the fastest car winning under deft handling. There was a distinct winner in each of the four classes. In accordance with the good fortune that has ever surrounded this race, there was not a major accident of any kind. The police, 2000 strong, maintained a clear, safe course throughout the running of the race. The day was fine and clear with plenty of warm sunshine and a gentle breeze. The course was not in top-notch condition, being rough in some places and dusty in others. There was very little crowding on the part of the contestants and no mishap resulted from what was experienced.

The only jarring element was the disqualification of the Mercedes car. In this regard it may be said that professional races, such as the annual Fairmount Park events, are run according to binding rules. These rules are framed to give equal justice to all the contestants and the section that specially applies to the case of the Mercedes provides that the driver and mechani-

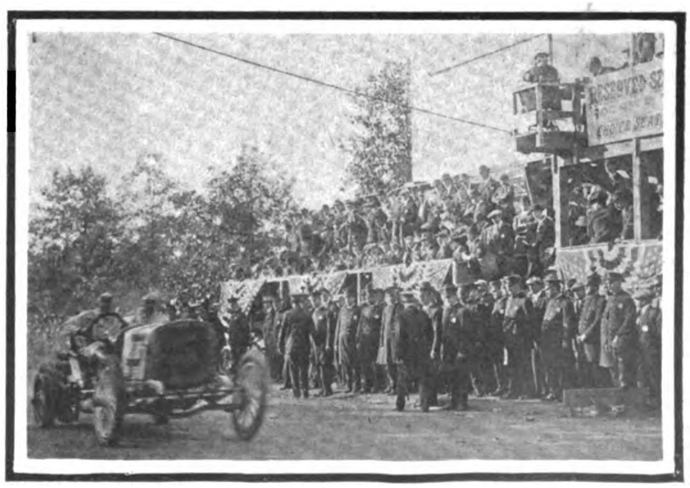
The race was well attended despite the postponement



There were bluecoats galore to keep the crowds within bounds

New Palace an Architectural Gem

HOUSED in one of the most beautiful buildings in New York, the automobile show to be given under the auspices of the National Association of Automobile Manufacturers, January 10-17, promises to be a vast success.

With a typical line of cars represented, consisting of the cream of the independent manufacturers as well as of the members of the N. A. A. M. that are not connected with the Automobile Board of Trade, gasoline pleasure cars, electric pleasure vehicles and commercials and gasoline deliveries and trucks will be shown. They are sufficiently numerous and typical of all branches of the industry to form a fitting companion-piece to the Madison Square Garden show.

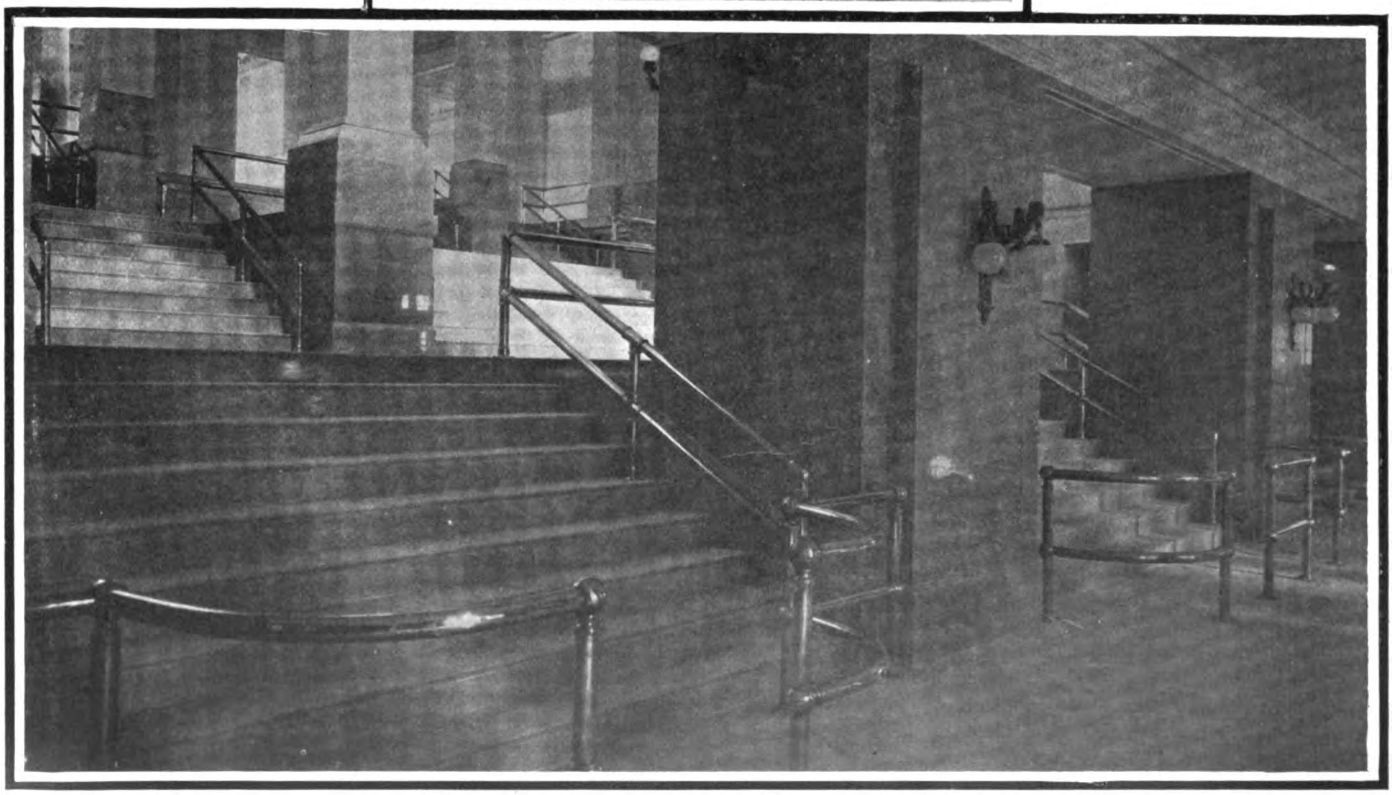
All but two of the passenger automobiles to be displayed will be shown on the main floor of the new Grand Central Palace.

The second floor will be devoted to the exhibition of trucks and commercials of various kinds, together with the two passenger cars that could not be accommodated on the main floor for reasons of space.

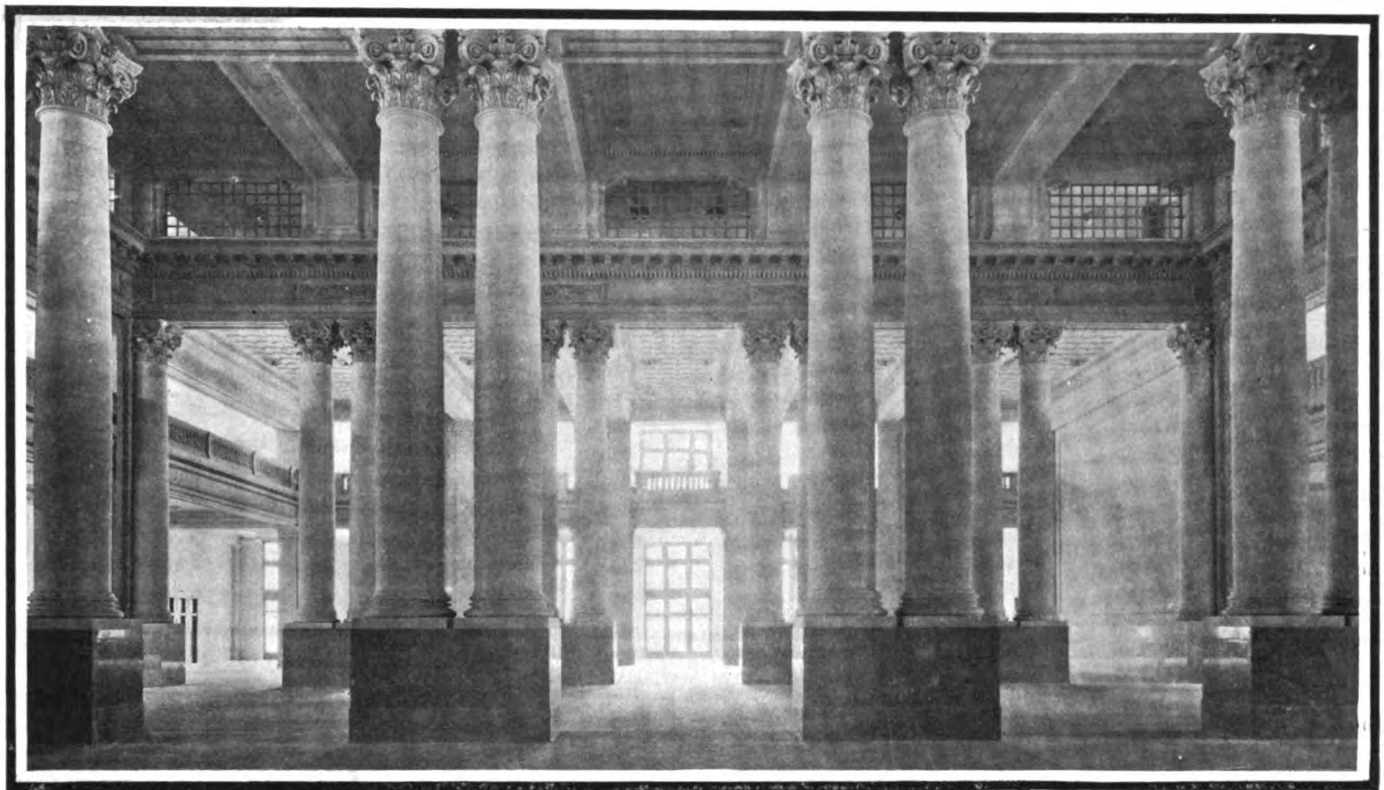
The third floor is to be used for exhibiting accessories. In the main, the spaces assigned to the various companies at the drawing last week will be occupied by them during show week, but there will be some changes as usual. Besides these, there will be quite a number of additions to the exhibitors and perhaps a withdrawal of two. The changes generally result from the desire on the part of exhibitors to swap spaces and even during the drawing there were several concerns negotiating for an exchange of spaces.

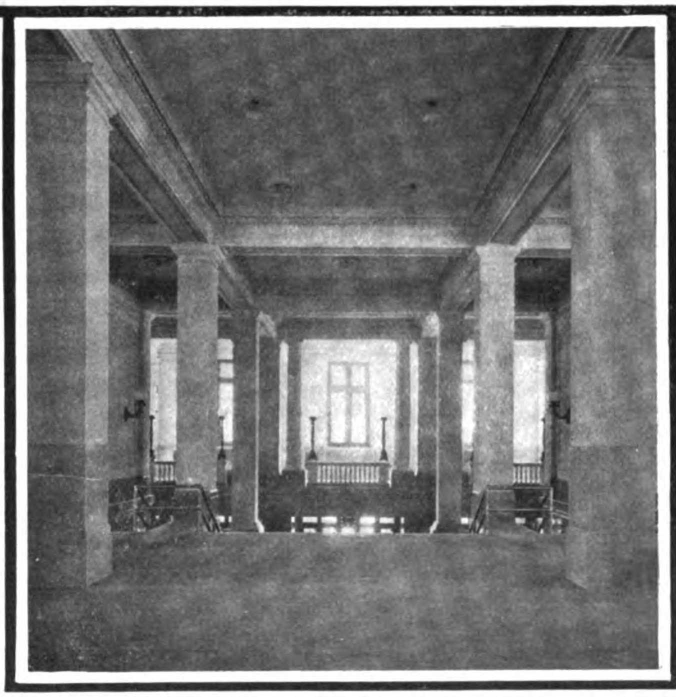
The first drawing resulted in filling the big main floor with pleasure-car exhibitors and considerably more than half filling the second floor with commercials. Mr. Miles announced after the meeting that there would be enough applications filed this week to take up all the available space in the truck section of the Palace show.

There was only one protest filed following the distribution of space and that resulted from the rule that had been adopted, placing the commercials on the second floor. The Gramm company objected strongly to



(Upper) Exterior view of New Grand Central Palace. (Lower) Grand stairway leading from street level to main floor





(Upper) View of the colonnade on the main floor, showing detail of pillars.
(Lower) Looking toward head of grand stairway from main hall

this arrangement, claiming that the space awards should have been based upon the number of shows that the companies had participated in and the amount of business done by them.

The protest having been overruled, the company selected a prominent space at the corner of the open court.

As compared with last year, the situation was a love-feast. Represented at the drawing were prominent members of the trade, who formed the backbone of the independent movement in the past, discussing positions in the exhibition hall with the wheel-horses of the parent organization. Every concern that makes good automobiles was sought for and their representatives responded in large numbers to the call.

Some of the spaces secured on the main floor by concerns that are just making their début are notable for their size and position. This is particularly true of the Hupp Corporation and the Stutz.

The building fronts on Lexington avenue and is twelve stories high. Around the top pair of stories is a collonade effect that gives a Moorish ascept to the structure.

Entering from Lexington avenue, visitors ascend a broad stairway to the main floor. From the top of the stairs the hall stretches away for 200 feet to the rear wall of the building. To left and right are the passenger elevators flanked by prominent exhibition spaces. Back on the Lexington avenue end of the room, extending from one wall to the other there are show spaces. but the solid body of exhibitors will be ranged about the great hall between the top of the stairs and the Depew Place side.

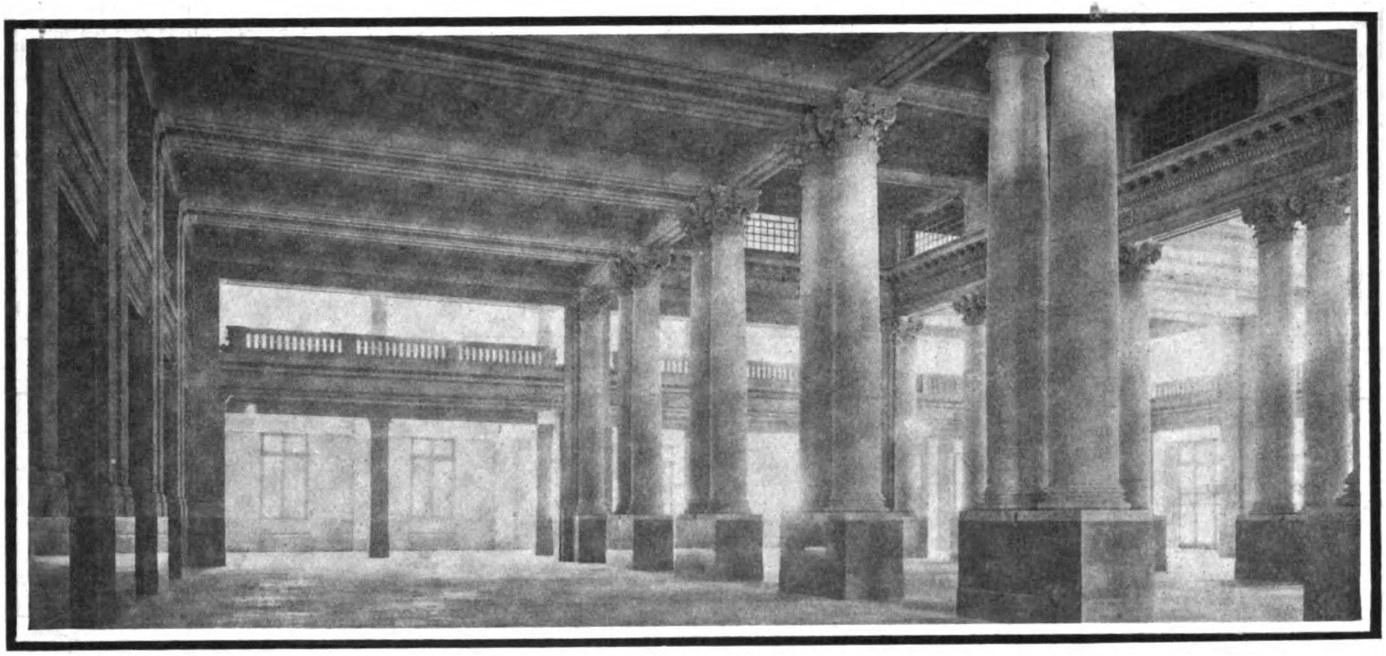
The tone of the interior is white combined with cream, the latter color being furnished by the stone work in the pedestals of the pillars and in some of the painted surfaces. The lights are set into the ceiling in such a way as to avoid glare and at the same time shed an ample volume of radiance. The whole floor is a giant quadrangle, surrounding a smaller one, in the form of an open court of great size, situated well toward the rear. This court is open to its full width as far as the ceiling of the second floor and pierces to the top of the third floor in reduced dimensions. Ranged in pairs, laterally through the hall, are two series of pillars of monumental size and massive beauty.

Besides these there are numerous pillars of smaller size in all parts of the building. These serve to support the exceedingly heavy structure and are not unsightly. But they do serve to cut up the hall and they do obstruct the general view.

The available space on the second floor is less than on the main or the third floors, this being due to the space lost on the second floor by reason of the open court. However, this is partially balanced by the space gained over the stairway. The third floor is still larger because the court is reduced to small size and it constitutes the only break in the floor which measures 194 by 268 feet.

Near the northeast corner of the building are the freight elevators. The shafts are covered with building material except for the side where entrance and exit to them is had.

The applications for space indicate that about 250 different



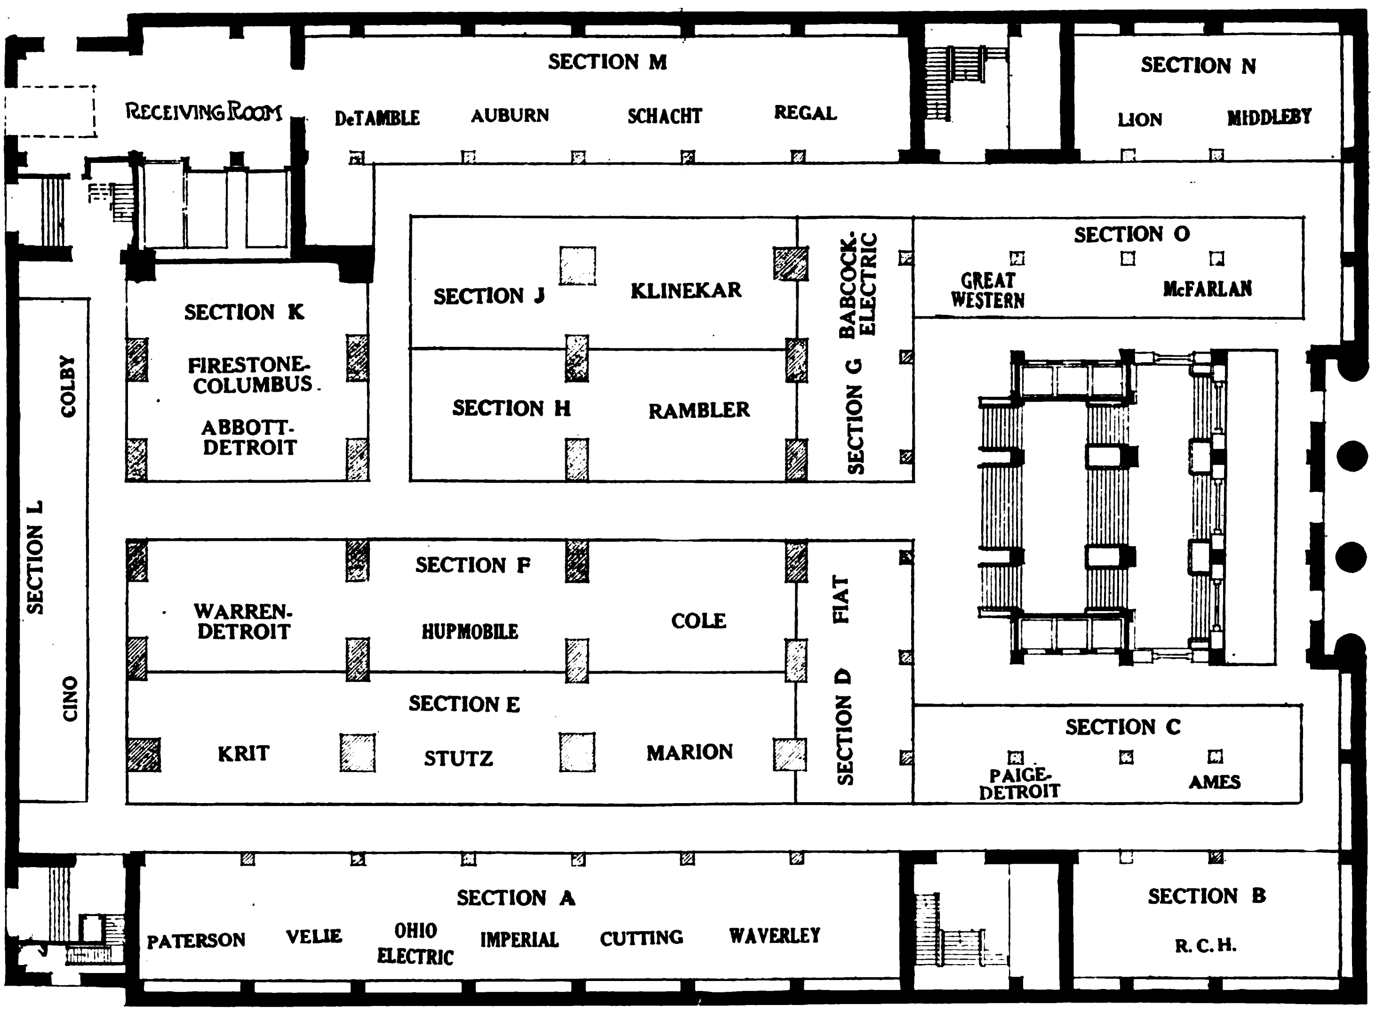
View of the main hall of the New Grand Central Palace, looking across the Colonnade

models will be shown. The exhibitors sought space to accommodate from 2 to 8 cars and 55 bidders were located in the building. There will probably be a dozen additional exhibitors, thus making four the average number of cars displayed.

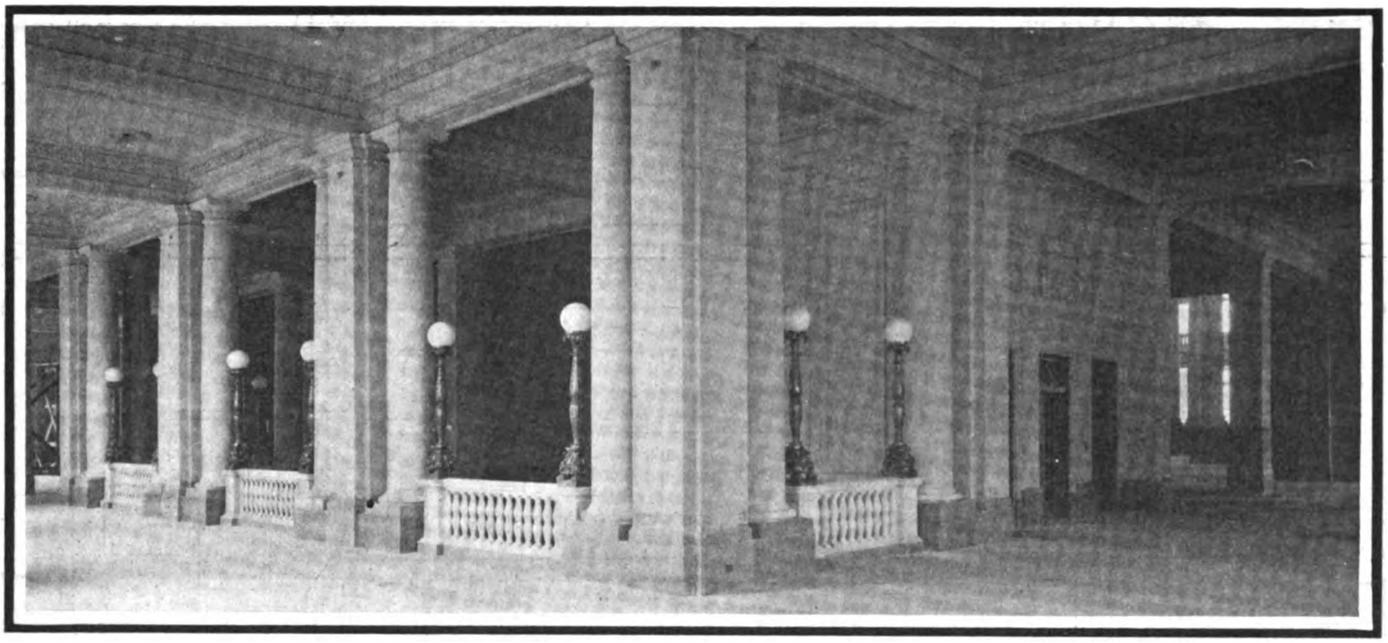
The plan for decorating the interior is still unsettled. As the building stands it requires very little in the line of beautification and it has been practically decided that simplicity will prove more effective than ornateness.

The building is being used this week for the electrical show and the promoters have been exceedingly sparing of decoration. The effect is very good.

The executive offices of the company are located on the



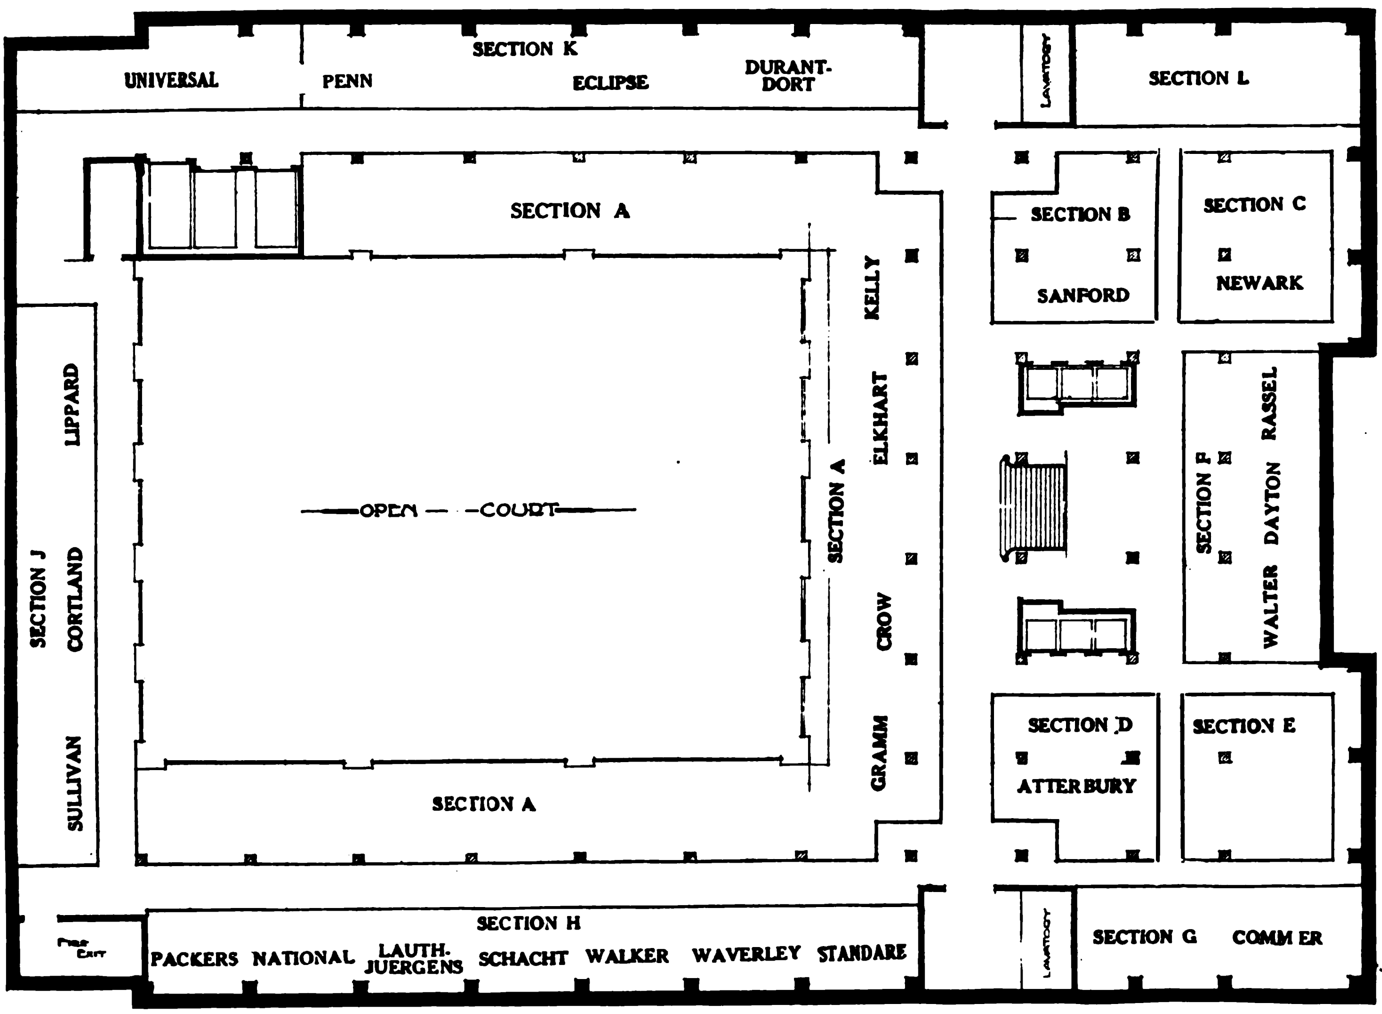
Floor plan, showing how the main floor exhibits will be installed at the 12th annual N. A. A. M. Show in the Palace, Jan. 10-17, 1912



Giving an idea of the decorative effects on the second floor of the New Grand Central Palace

ground floor in the southeast corner and cut off nothing from the main floor, thus diminishing in no way the available exhibition space.

The floor space of the exhibition part of the new Grand Central Palace is something over 120,000 square feet. This total is considerably greater than the exhibition space of any other building devoted to shows in the United States. Despite this fact, the division of the space into three floors and the presence of so many pillars in each does not give the effect of such a vast amount of room. The architectural impressiveness of the main floor is not carried out in the upper floors of the structure in the same measure.



Plan of the second floor exhibits at next winter's N. A. A. M. show in the New Grand Central Palace

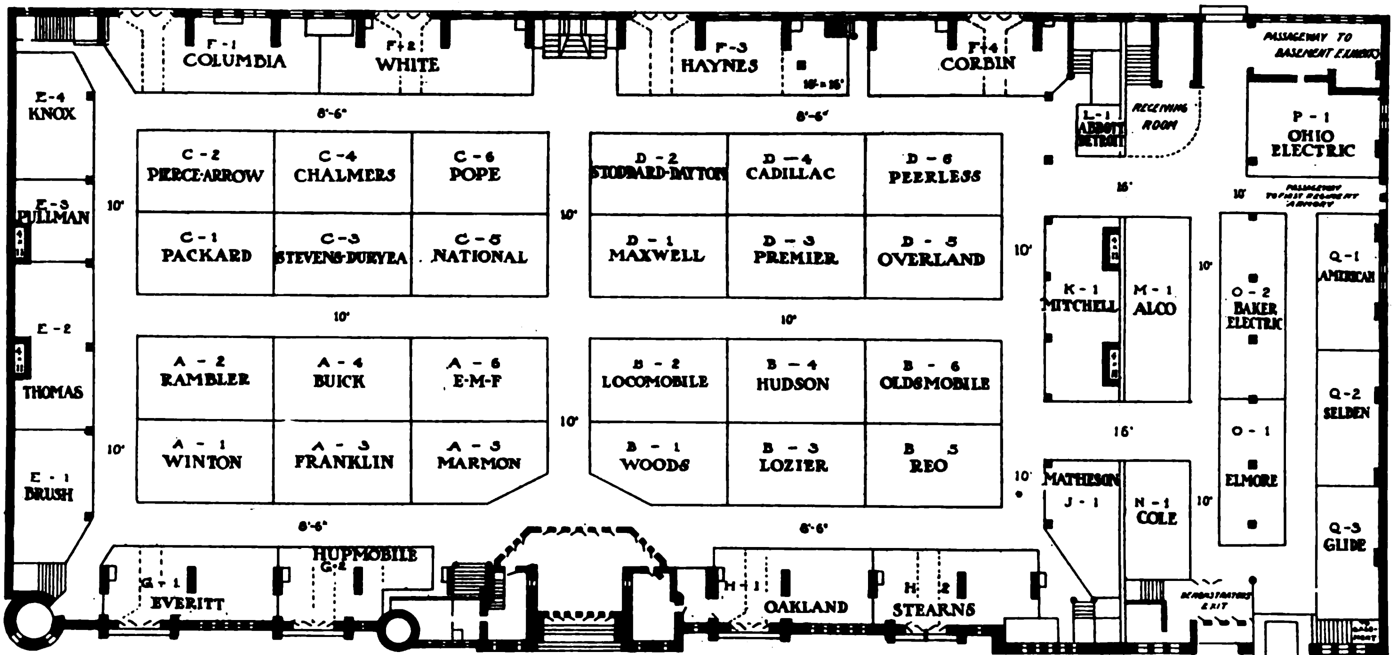


Chart of Chicago Coliseum and Annex, showing where pleasure cars will be located during N. A. A. M. Show, Jan. 27 to Feb. 3, 1912

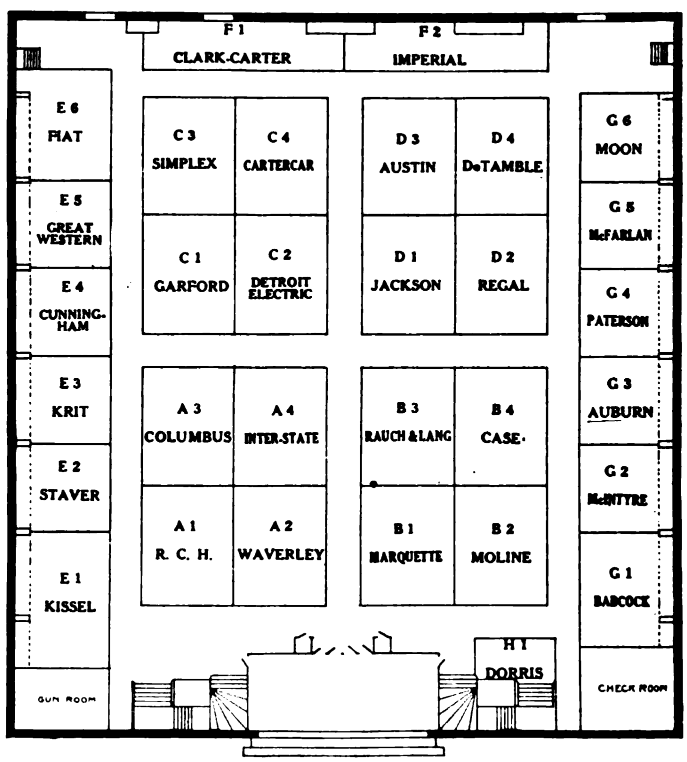
The N.A.A.M. Shows at Chicago

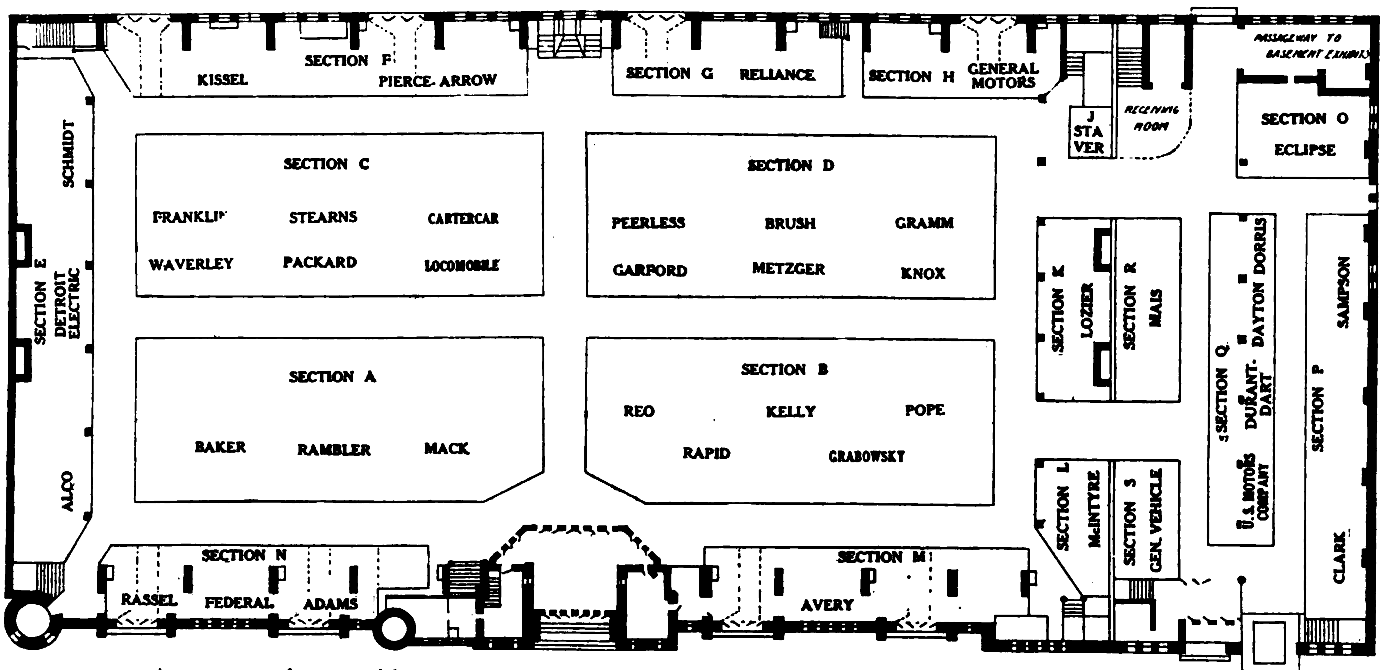
CHICAGO, Oct. 10—Although no announcement has been made by Manager Miles as to the principles and scheme of decoration for the Coliseum and Armory shows in Chicago in January and February, it is a foregone conclusion that both of these shows will be up-to-date in every respect. The pleasure car show will open on Saturday, night, Jan. 27, and continue until the following Saturday night. As soon as the doors close on it the exhibits will be removed and the following day the commercial car exhibits installed so that the commercial show can be opened Monday afternoon or evening, Feb. 5, and will continue until the following Saturday night.

The setting for both of these shows will be identical with former years. Two buildings will be required. The Coliseum on Wabash avenue will be the big exhibit hall; the second building is the First Illinois National Guard Armory, which is on Michigan avenue. The rear entrance of the Coliseum opens onto the alley leading to the rear entrance of the Armory, so that both buildings can be combined by constructing an enclosed walk along one inside of the alley. Tickets of admission to the Armory are given when leaving the Coliseum by the rear entrance and *vice versa*. This arrangement makes the two buildings practically one and gives the exhibitor in the Armory as good a chance at exhibiting his wares as his rival in the Coliseum.

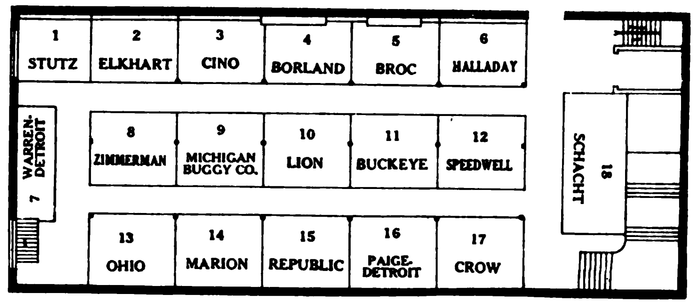
As in previous years during the first week, the main floor of the Coliseum, the Coliseum annex to the south end of the Coliseum and the annex basement will be given over entirely to pleasure cars; the gallery of the Coliseum and the annex will be placed at the disposal of accessory manufacturers. In the Armory the same rule will hold; namely, cars on the main floor and accessories in the gallery. It is expected that the majority of the accessory exhibitors who will show during the pleasure car week will leave their exhibits for the commercial display during the following week. There will be, of course, not a few whose accessories are not intended for trucks or delivery wagons and they will not remain. The tire makers will undoubtedly change their exhibits, the pneumatics of the first show being replaced by the huge solid rubber truck tires for the second week's exhibition.



How pleasure cars will be distributed at the First Regiment Armory



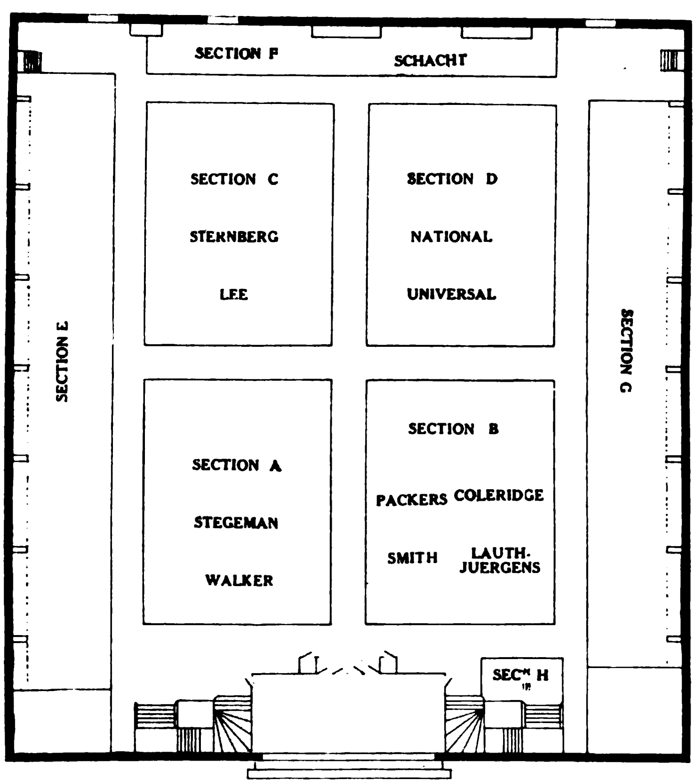
Arrangement of commercial cars which will be exhibited during the show in the Coliseum and Annex, Feb. 5-10, 1912



Plan of basement of Coliseum and layout for pleasure cars

The Chicago show has since its inception been a wide-open exhibition and will be so for the coming year. In the days of the A. L. A. M., when New York had its licensed show in one place and its independent show in another place, these licensed and unlicensed makers were exhibiting side by side in the Coliseum or Armory; and next year the Board of Trade members will be side by side with those who are not members of this organization. Barriers are entirely removed; it is an out-and-out national show. In the selection of exhibit spaces priority of selection has always been given to those makers who have been the oldest exhibitors at the Chicago shows. Because of this scheme it is possible for nearly all of the old companies to group themselves on the main floor of the Coliseum. In this way one of the smallest makers is often lined up against some of the biggest producers of high-priced automobiles to be found in the country.

In the matter of show decorations, Manager Miles has always shown special versatility and a good scheme is anticipated for the coming show. He was the introducer of the uniform scheme of decoration, which has been adopted all through America and is being used in many of the big exhibitions in Europe.



Space arrangements for commercials at the First Regiment Armory

Chicago Show Week

Chicago, Oct. 9—Chicago is trying an experiment this week which, if successful, will be copied by other cities. Affairs somewhat similar to it have been held, but no other city has such a stage as is afforded by the local motor row, 2 miles in length. The experiment is the fall opening of the Chicago Automobile Trade Association, which has taken the form of a combination outdoor and indoor display. The exterior of the show consists of Michigan avenue, decorated at night by countless numbers of incandescents strung crosswise of the street and with handsome lighted posts at each corner. The stores are decorated uniformly with autumn leaves, potted palms and flags and, taken as a whole, the row presents a handsome appearance.

Nearly every concern has on view the 1912 models and every effort is made to bring out the crowds at night, when the stores are kept open until 10 o'clock, the idea being to get the names of prospects who can be worked on during the dull months of Winter. To encourage the people to visit the row the Trade Association is running a trackless trolley made up of demonstrating cars which carry spectators from one part of the row to another, provided they secure tickets from some agent, who takes the name before handing out the pass.

Crossing the Canadian Rockies Feat

A Glorious Vacation Trip

1—At the summit of the Crow's Nest Pass on the backbone of the continent
2—Some of the going was equal to that afforded by fair country roads
3—Where a boiling trout stream has cut its way through the living rock

CROSSING the Canadian Rockies from Calgary to Windermere, a feat never performed heretofore in automobiles, two carloads of tourists, consisting of members of the Calgary Automobile Club, recently enjoyed an experience that was glorious.

They spent three weeks on the trip and only traveled 1,133 miles, but for eight days the party camped and fished the streams and lakes high in the heart of the mountains. According to Herbert Mapes, one of the party, the roads and trails were extremely difficult, but the magnificent scenery and the pleasure of the trip more than repaid the pains and trials that were suffered through the racking of the bad roads.

Guns, fishing tackle and a complete camp outfit were carried. The largest mileage made in any day was 128 miles, the distance from Calgary to MacLeod. After getting up into the hills the average distance traveled each day was about 50 miles and on several days the route traversed was cut down to 25 miles.

Leaving MacLeod the way led past the little city of Frank, B. C., where once stood another village of the same name. Deep under boulders and earth that slipped upon it from the mountain tops the former village and 80 of its inhabitants are buried. This part of the route is very dangerous, even to-day, because the formation of the mountain surface is not secure and slides are of daily occurrence.

The next day found the party augmented by another automobile and the three cars climbed the terrific grade and narrow rutted trail to Crow's Nest Pass, which is at the summit of the continental divide. Looking back from Crow's Nest the party saw streams and brooklets that eventually empty into the Atlantic Ocean, while to the west the watercourses flowing through the broad valley that lies between the Rockies and the Selkirk foothills, trend to the Pacific.

On the very summit the tourists found a house, from which the rain is shed on one side into the Atlantic Ocean and from the other the dripping moisture finds ultimate rest in the Pacific.

Legend says that two other automobiles once tried to surmount Crow's Nest, but sticking in the mud, both had to be towed to the summit by the aid of horses. In this case all three cars reached the top by the power of their own engines. Mr. Mapes estimated that the grades at their steepest pitch approximate 45 per cent. After passing Crow's Nest the trail led downward to the floor of the valley, from which stretched away the foothills of the Selkirks.

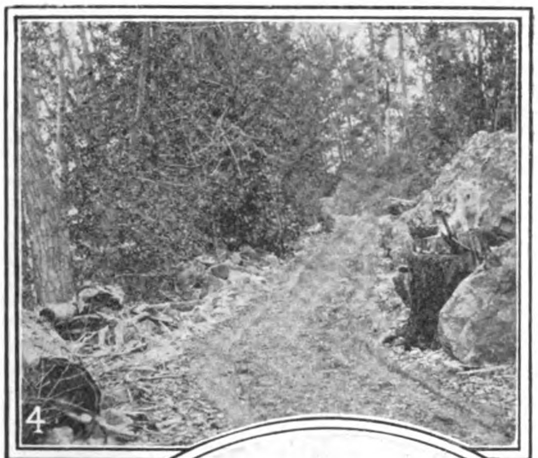
The route across the mountains was through a country where inexpressibly grand scenery is the ordinary thing. Bald crags, thousands of feet high, stand out from the grim mountain sides, while along the trail, turning the blackness of the highland lichens to green are numerous springs and brooklets that trickle toward the valleys to form the tumultuous trout streams and shimmering lakes which abound in this region.

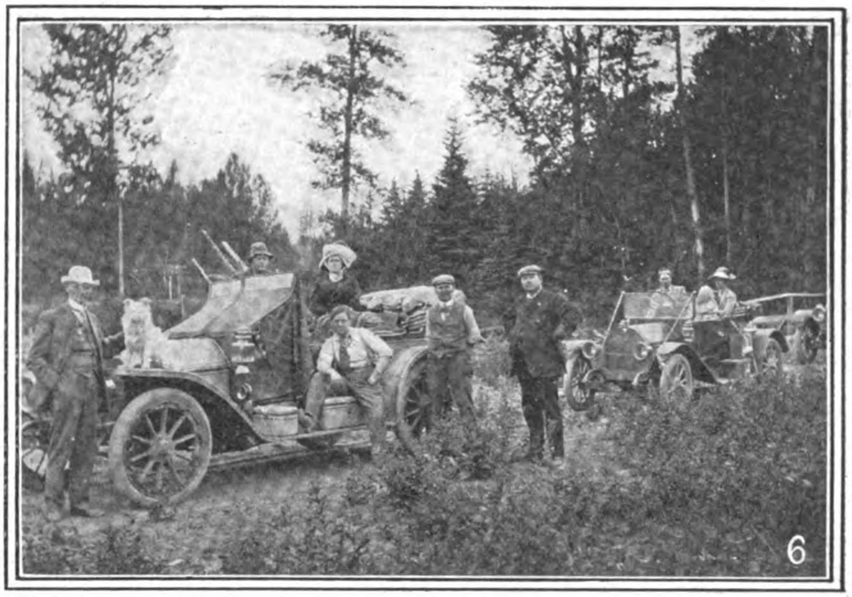
Canyons and heavy woods, where the most vivacious members of the party were hushed by the grandeur of the silent pines, were incidents of the downward trip, which was concluded at Krag.

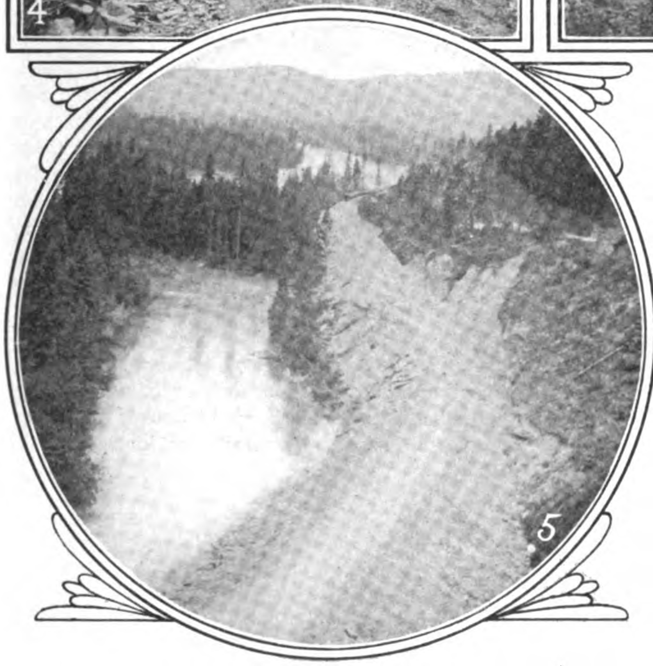
The next day the party proceeded to Windermere, 117 miles, requiring over 12 hours' steady running, and the following day

# of Calgary Automobile Club Members

Over Continental Divide







4—In reaching Lake St. Mary's the cars had to traverse this road
5—Just before Waldo, new road construction was passed by the party
6—Less than two hours to midnight this picture was taken near Krag

The perpendicular climb from the west side of the plateau to the summit of the Crow's Nest is 610 feet and the cars made it in 20 minutes over a trail barely wide enough for the tread of the wheels, and at the top found the way down blocked by a load of coal, which was being dragged up to the summit of the pass by a 4-horse team. In order to get around this obstacle the wagon had to be hauled out so that its wheels on one side touched the edge of a precipice bounding a 90-foot drop. The animals were then unhitched and by dint of tight squeezing and the loss of some paint from the tonneaus the cars managed to pass.

There was not a single unpleasant incident during the entire trip, if one may disregard the meeting with the coal team. The tourists enjoyed every minute of it, and all declared that they intended to repeat it next Summer.

was spent in making an ineffectual side trip to Horsethief Creek, where it had been intended to camp for several days.

This was not done, however, and camp was made on Lake Windermere for the next four days. There was little fishing to be had, and after enjoying the fun of living out in the open for that period of time the party entrained again and proceeded to Cranbrook and from there to Lake St. Mary's.

The return trip, which really should be figured from Windermere, was somewhat longer than the outward bound journey. After leaving the lake the way was through Cranbrook, Fort Steele, Wardner, Baynes Lake, Elko, Morrisey Hills, Fernie, Hosmer, Crow's Nest, MacLeod and into Calgary.

The trip required just 21 days and was staged among the most beautiful scenery to be found in Alberta and British Columbia, if not in the whole world.

The cars used by the party were a Cole and a Stearns, while the car that joined the Calgary tourists before reaching Windermere was a Hudson. On several of the days the party covered too much territory to enjoy to the uttermost the scenery.

Southland Calls to the Tourist

So powerfully has the Wanderlust caught the motoring public that inquiries have already begun as to the delights of a tour to the Southland.

And the answer is that the trip makes a real experience and a pleasant one. The South has awakened in some measure to the importance of good roads, so that occasional stretches will prove excellent, while the average roads are tolerable. Two routes in the Automobile Blue Book have been very fully detailed in the 1911 edition, Volume 3, and no tourist should attempt the trip without it. One of these routes is known as the National Highway and the other as the Capital Highway. More parties than the uninformed would suspect have made the trip.

Of course the great charm of the tour is the scenic beauty of the South. In Virginia "where cotton fields touch the edge of the swamps, where jasmine blooms on the rail fences, and peach trees by every cabin, the cardinal lifts up that voice of the troubadour, so gay, so debonair." In the Carolinas is the glorious belt of pines. And finally, in Florida, is the playground of the motorist.

Pulverized Coal--a New Fuel

Is Thirteen Times Cheaper than Gasoline--Offers Good Inducements for Commercial Work

By Prof. William D. Ennis.

UNDER fairly intelligent operation, and with reasonably good luck, the leading items of running expense in connection with an automobile are fuel and tires. Which of these two is the more important depends upon many factors, such as weight and design of car, roads, speeds, size and type of tires, care in running, etc., but in few applications is the cost of fuel other than an important item.

The fuel in this country is usually gasoline. At a cost of says, 20 cents per gallon of about 140,000 B.t.u. heat value, we buy in gasoline 7,000 B.t.u. for 1 cent. With a thermal efficiency of the motor of 15 per cent. (from heat in fuel to work or power at the tire) we obtain in actual pulling power $7{,}000 \times 0.15 = 1{,}050$ B.t.u for 1 cent. If a fuel were available which afforded this amount of developed horsepower at a cost of 1-6 or 1-7 as much, the expense for fuel would be reduced to 1-6 or 1-7 its present usual rate in the operation of automobiles, and the total cost of running would be reduced in no small degree.

Gasoline is one of the most expensive of fuels, quality considered. About 7,000 B.t.u. are obtained for 1 cent. City gas containing 600 B.t.u. per cubic foot, at $1.00 per thousand cubic feet, gives only 6,000 B.t.u. for 1 cent, it is true; but crude (fuel) oil at 3 1-2 cents per gallon gives 40,000, and coal of 14,000 B.t.u. heat value at $3.00 per ton gives 93,000, or 13 times the return from gasoline. The railway locomotive uses such coal; the automobile is handicapped by the necessity of using gasoline.

Commercial Uses of Pulverized Coal

This seems to be solely a question of convenience. High-priced fuels are sometimes used on account of their small bulk, as when a warship employs fuel oil at twice the cost of coal, because a cubic foot of such oil may weigh 60 pounds and represent, potentially, 1,250,000 B.t.u., while a cubic foot of coal weighing 50 pounds, would yield only 700,000 B.t.u.—little more than half as much.

In certain industrial applications, where conveniences or control of combustion necessitates the use of fuels other than ordinary coal, there is keen competition between liquid fuel, natural gas and pulverized coal. Natural gas is not everywhere available, and the supply is everywhere decreasing. Liquid fuels, in this part of the country, cost on the average, per available unit of heat, about twice as much as pulverized coal, which is consequently largely employed in cement burning and for various heating furnaces. A fourth competitor, which seems destined eventually to supersede this fuel, is industrial gas; but excepting in blast furnace work, this has not yet been developed to any extent.

Powdered coal is coal which has been so finely ground that it looks and acts not unlike gunpowder. The coal selected for pulverizing is usually a high grade, highly volatile and fairly dry bituminous—one which along the Atlantic seaboard sells at a rather high price. Contrary to a prevailing impression, pulverizing is not likely to provide a method for utilization of the waste products of the mines. The grinding is usually expected to reduce the coal to 60 or 80 mesh; sometimes to still smaller size. The pulverized product is irregularly inflammable. A lighted match, thrust into it, will be extinguished; but a floating fog or cloud of the dust in a badly ventilated room may ignite and burn explosively in consequence of accidental local overheating or of contact with spark or flame. Several accidents have occurred from such causes.

Combustion of Powdered Coal

In a furnace this fuel acts like gas or oil, giving an intensely hot, pervasive and controllable flame, which may be easily adjusted to develop maximum combustion efficiency. Like all soft coal, it burns with a long flame; but smokelessness is possible without special combustion chambers unless the load is heavy or rapidly variable. The stream of coal is swept or blown into the furnace and is of course quite invisible. If allowed to strike a bridge wall or arch, the localized high temperature and blowpipe action are highly destructive.

The ash (from such a soft coal as is usually employed for pulverizing), is a heavy fine powder, for which there are applications in the arts. In clinkering habit it resembles the ash from the unpulverized coal. If a fuel is used the ash of which does not clinker in ordinary operation, it will not clinker after pulverizing. If an automobile can run 14 miles on 140,000 B.t.u. of gasoline, using, say, 1-2 pound of gasoline or 10,000 B.t.u. per mile—and the same machine should require (for reasons which will appear) 1 1-2 pounds of pulverized coal (20,000 B.t.u.) per mile—about 0.15 pounds of ash would be produced for every mile traveled, or about 1.66 cubic inches. On a 20-foot roadway, for every 10,000 automobiles which passed there would then be deposited an ash layer equivalent to a uniform thickness of 0.0011 inch across the whole width of the road. A long time would be needed to macadamize the road with powdered ash!

This fuel burns without odor and (as has been stated) may be burned without smoke. With an ash production of 1.66 cubic inches or 0.15 pounds per mile (say 0.2 grain per foot), it could also be called dustless.

Relative Efficiencies

The powdered coal weighs about 81 pounds per cubic foot, containing about 1,130,000 B.t.u. A cubic foot of gasoline may represent just about the same heat value; so that from this standpoint there is no difference as regards storage capacity. But if a heat unit from gasoline gives more power than a heat unit from coal, then there is a difference to be considered.

Gasoline is burned in an internal combustion motor, where it may easily develop a thermal efficiency between 15 and 20 per cent. Any immediate application of pulverized coal would have to contemplate the burning of that fuel in a steam boiler which should drive a steam engine, the combined efficiency being probably not much over half that of the gasoline motor. For a given radius of action, then, the room for fuel storage would have to be about doubled if the coal were used.

Pulverizing Processes

For over a century the possibility of an engine using a solid fuel in an internal combustion cycle has been intermittently discussed. Some engines of this type have even been built and run. Solid gasoline is one of the most recent developments along this line. If pulverized coal could be employed directly in the cylinders of an internal combustion engine, it would stand on a parity with gasoline, as far as the storage question is concerned.

In preparing soft coal, it is usually necessary to expel some of the moisture before grinding. A preliminary partial grinding may precede the drying. The object of drying is twofold. It decreases the power consumption at the pulverizer, and it facilitates the handling of the pulverized material, which, if too wet, sticks like a snowball and cannot be easily transported or fed to the furnace by ordinary machinery.

The dryer is usually one employing direct heat, although steam dryers were formerly employed. The expense for fuel does not ordinarily exceed 1 per cent. of the cost of the fuel treated. Some power, also, is needed to rotate the dryer cylinder and to operate the fan which circulates the hot air; the aggregate equivalent of these amounts of power, reduced to a fuel basis, will not exceed one-half of 1 per cent. of the fuel treated in the dryer.

After drying, the coal is reduced to the pulverized condition by one of the many commercial types of grinder, all of which are expensive to purchase and maintain. The original grinding machines were burr-stones or stamp mills. The most perfect apparatus is the tube mill, which is, however, extravagant in power consumption. The centrifugal roller and ring mill is a common type at present; the rolls are sometimes replaced by hardened steel balls which run at high speed in cast metal races. Still another form of mill has radially inserted cutters which shred or tear the coal.

Very few reliable tests have been made on the power consumption for grinding; this varies tremendously with the type of mill, the size and condition of the raw material fed, and the fineness of the product. Roughly, 1 horsepower will grind to an average of 80 mesh from 100 to 200 pounds of coal per hour. In most pulverizers, the powdered product passes over a screen, any coarse particles (sometimes aggregating as much as 30 per cent.) being returned to the pulverizer. In one form, a settling chamber is provided above the grinder proper. From this an exhaust fan draws off the product by suction; its speed being regulated so that the fine particles only are removed from the mill, while the coarse are being returned to the pulverizer by gravity.

The powdered product is usually transported in closed screw conveyors and link belt elevators, and stored in small isolated bins, tightly covered.

It must be fed into the furnace continuously and by some mechanical device which mixes with it the necessary supply of air for combustion. Gravity feed is impracticable, because uncontrollable. In the Schwartzkopf system, the dust is swept in by a revolving brush. Air injectors are also employed; a supply of compressed air is then necessary. A rapidly revolving horizontal screw conveyor itself fed by gravity, is one of the most common devices. In all systems, power is required; the amount of this power is small, but its provision adds some complication; and in many systems an additional fan for supplying air is necessary.

To summarize with regard to the described standard form of equipment, pulverized coal involves an expensive plant, preferably with duplication of units; the total cost of pulverizing and feeding, under ordinary conditions, is from 50 to 60 cents per ton. The fuel is dangerous to handle and store, so that its preparation should be continuous, and pulverizing should be carried on at about the same rate as feeding. With standardization, storage provision may be surrounded with such proper precautions as to make it reasonably safe. A highly volatile soft coal must be employed.

Application to Steam Boilers

In connection with the Aero apparatus, these statements are subject to some modification. Here unit pulverizers are used one directly in front of each furnace. They receive the sized coal just as it comes from the cars and feed the powdered product directly into the furnace where it is to be burned. Even high percentages of moisture may be taken care of in this type of plant; but no doubt at excessive power consumption. The whole process of pulverizing is here carried on in one self-contained machine.

Any finely divided fuel is apt to be burned at higher efficiency than solid coal. Pulverized coal in steam boilers would be on the same basis, with regard to evaporation efficiency, as liquid or gaseous fuel. Its use would largely dispense with the labor of firing ordinary coal, which might under average conditions mean a saving of 20 or 30 cents per ton. If the gross cost of pulverizing be taken at 60 cents and the labor saving at 30 cents, the net additional cost of 30 cents per ton must be contrasted with the thermal saving as between pulverized and ordinary coal. If the latter costs $3 per ton, the 30 cent disadvantage would be just offset by a 10 per cent. gain in efficiency.

The automobile having a steam power plant already uses a liquid fuel, so that there could be no gain in efficiency. Nor could there be any saving in labor expense. In a steam locomotive, these savings might be realized; in part, at least. The independent self-contained type of preparatory apparatus would be necessary, or else pulverizing plants would replace present coaling stations and the locomotive could "coal up" as quickly as it now takes water. It might take on coal even while running. If the power for driving the feeder were derived from the locomotive boiler itself, the latter would cease to be self starting, and outside power would be necessary in order to get the fire going.

The Automobile

Some of these considerations apply with equal force to possible applications of pulverized fuel under automobile conditions. The figures assumed show soft coal to be 13 times cheaper, in proportion to its heat value, than gasoline. If we say that the steam plant to be used is half as efficient as the internal combustion motor (letting this rough estimate cover the cost of preparing the coal), the saving in fuel cost is still 11-13 or 85 per cent. Fuel would need to be taken on twice as frequently as at present. For commercial vehicles, making regular trips, pulverizing stations might be placed at suitable points and this ready prepared fuel discharged into a storage bin under dust-proof connections. In order to start up a cold boiler, a short period of hard feeding might be necessary.

For the ordinary consumer, the charge would be more revolutionary. The self-contained pulverizing and feeding apparatus would be a radical addition to present equipment, one which might prove intolerable. On the other hand, central pulverizing stations with generally distributed supply depots would be hard to inaugurate and would be unavailable unless inaugurated on an extensive scale. The 85 per cent. predicted saving would, however, give an opportunity for considerable profit to both producer and consumer of the fuel.

Should there be developed an internal combustion engine which could use the pulverized coal, the additional saving in fuel would be from present standpoints unimportant; but the maintenance of present radii of action and the possibility of easier arrangement for self-starting would make the fuel more attractive. It seems probable that under such conditions a strong effort would be made to adapt the self-contained preparing and pulverizing apparatus to automobile conditions. Only a small amount of prepared coal would need to be stored; but the unpulverized material for consumption would still occupy about twice the space of the present gasoline supply, so that there would be an enormous addition to the present bulk of power plant.

The outlook for a realization of an 85 per cent. saving in fuel cost by this means is obviously not encouraging, yet this is so large a saving that it necessarily obtains occasional consideration; and it is by no means impossible that we may see stage and trucking lines equipped to burn pulverized coal. Whether this will be in a steam or a gas engine is doubtful. Whether it will involve local coal supply depots and feeding spouts, or coal bins and pulverizers on the automobiles, the answer is also doubtful. It is to be hoped (and, one may say, expected), that a change of the sort, if made, may be made without adding to the present discomfort of machine occupant or passer-by, on the grounds of noise, dust, smoke, odor or any other kind of nuisance.

Quick Methods of Car Painting

By M. C. Hillick.

RAPID transit processes for painting the automobile are being exploited throughout the country and promise to be largely in evidence next year. By temperament and disposition, by the teaching which the use of the horseless vehicle brings to its owner, the latter is inclined to be in a hurry.

This nervous haste follows the car into the paint shop and exacts the greatest possible speed in getting it into a new dress of paint and varnish. This brings us to the question of the briefest method consistent with reasonably durable results.

For the metal body scarcely anything shorter than a 5-day method can be offered, which represents for the first day the work of going over the surface with a coarse rubbing composition stone dipped in benzine or naphtha. Sand blasting the surface, in case of new work such as we are now considering, is the best and surest method of getting the surface free from rust or scale formation; but the sand-blast machine is not always available in the automobile or carriage paint shop, hence the need of some effective hand system which will prove at least a fair substitute for the machine. A stiff wire brush is a very good tool with which to eliminate the rust and foreign matter, but for good work, in the absence of a sand-blast machine, the composition rubbing stone and benzine is a good combination.

Having made the surface clean and receptive, apply a good metal primer, of which there are many being marketed ready to use. All things considered, these ready-to-use primers are cheaper, and, as a rule, more uniform and reliable than those shop-mixed and prepared.

The primer should be dry enough the following day to run over with a thin glaze of hand-drying putty, working the mixture on very smooth and uniform. The morning of the third day sandpaper this putty glaze sufficiently to fetch it down fine and smooth. Then apply a coat of body color, japan ground, and thinned with turpentine to flat out without any gloss. Late in the afternoon of the same day apply a coat of varnish color or glaze color. Late in the afternoon of the day following run over the varnish color with a soft sponge dipped in water and pulverized pumice stone to lay down the gloss and beat off dirt motes, etc. Then apply a coat of rubbing varnish, quick-drying, containing just enough of the pigment to preserve the natural tone of the color.

In the closing hours of the fifth day again water rub, using very little pumice stone flour, wash up and apply a coat of heavy body finishing varnish. During this time the chassis or running parts should be brought along to an equally quick finish.

This sort of finish, however, suffices for only a certain class of trade, and to make a finish acceptable to buyers and users looking for something between the cheapest and the highest-priced it will be necessary to put over the putty glaze at least three coats of rough stuff in due time, rubbing these out with composition rubbing stone and benzine, and using above the color an additional coat of rubbing varnish. This, of course, will lengthen the period for painting and finishing several days, but it will furnish a correspondingly higher class of finish.

Wooden bodies may be finished upon the same schedule outlined for the metal bodies. Upon the former apply a surfacing or glaze material bought ready to use, or made by grinding white lead through a closely set mill and then rubbing it to a working consistency with equal parts of rubbing varnish and coach japan, adding the necessary coloring matter to fetch surfacing base up to the finally selected color.

On the morning of the third day this coat or glazing should be sandpapered down, using the paper over a block, and using for the first sanding No. 1 paper, and for the final dressing down No. 0 paper.

For better surface results omit sandpapering the glaze stuff and apply directly over it, at the rate of two coats per day, four coats of roughstuff. The day following the application of the last coat of stuff rub out with composition rubbing stone and water. Then apply, in case of most colors, two coats of flat color and a coat of varnish color, unless some one of the cake pigments is used, in which case two coats of the varnish color, or glaze color, will be necessary. Upon this, or upon the final coat of varnish color or glaze, after rubbing lightly down with pumice stone flour and water, the striping and ornamental work should be applied. Then follow with a coat of clear rubbing varnish, this in due time to be well rubbed and finished with a stout body of finishing varnish specially adapted to automobile work. This latter is an important item in any system or process of surfacing and painting which may be adopted.

The service imposed upon the varnish of the automobile is by far the most exacting of any to which varnish can reasonably be exposed, the strain upon it being, both during service on the road and in the garage, of an unusual character. Careless methods of washing and caring for the car at garages in which the very life of the varnish is threatened, and, in a measure, taken, constitute the hardest kind of service, being even worse, on the whole, than the blinding dust and the foreign matter settling upon the car in the course of road service.

All methods of painting and finishing the car should be with an eye fixed upon securing with brevity of methods the greatest possible amount of durability, along with an appearance at once neat and effective. It is not always the greatest number of coats of paint and varnish that count for most in the matter of appearance and wearing capacity. Fewer coats, and better drying and application of such coats, will insure for appearance and durability something which less careful methods and any amount of paint and varnish must fail to supply.

Big Oil-Burning Motors for Commercial Use—The largest Diesel motor so far constructed anywhere is of the two-cycle type and develops 2,000 horsepower at 167 revolutions per minute. It has been installed, together with a Diesel motor of 1,000 horsepower, by the Electrical Society of Saint-Chamond, which has heretofore received all its current from a water power plant in the Alps Mountains.—From *Le Génie Civil*, July 29.

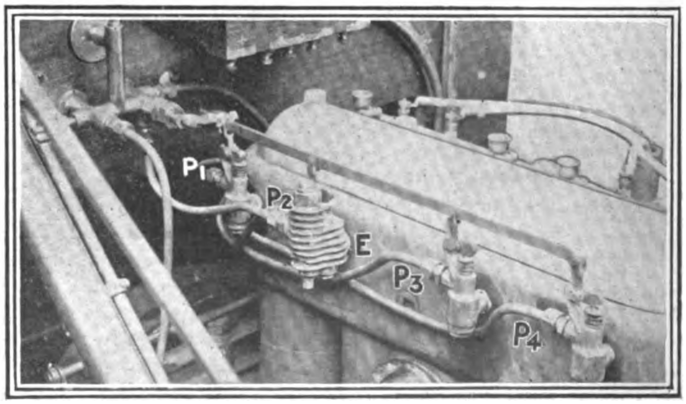


Fig. 1—Showing right-hand side of Everett motor, with self-starting device attached

Novelties in Self-Starting Devices

DISINCLINATION to work any harder than necessary has put the average motorist on the *qui vive* for anything new and promising along the line of self-starting devices. One of the more recent inventions having this object in view is that forming part of the regular equipment of the 1912 Everitt six- and four-cylinder models. This may be briefly described as of the compressed-air type, operated by a push-button on the dashboard. The supply of air pressure is taken from one of the cylinders on the explosion stroke, and in the case of the four-cylinder motor, shown in Fig. 1, it will be seen at E on the third cylinder.

The air-pressure storage tank can be filled by running the motor for five or ten minutes, after which the pump is automatically shut off. A selector valve, or distributor, operating on the same principle as an electric timer is directly connected with the camshaft. As the engine revolves this distributor exposes, in turn, four openings for the four cylinders, and air pipes P1, P2, P3 and P4 are led to each of the cylinders. The timing is so arranged that the air pressure from the tank passing through the distributor is admitted first to the cylinder which is at the top of its stroke.

A needle valve V1, Fig. 2, is provided on the dash for the purpose of closing the tank and connection when the car is left for the night, or for any length of time, the object of which is to guard against any possibility of leakage of air pressure from the tank. The gauge G1 registers the amount of pressure available for starting the motor. When it is desired to start the motor, provided the needle valve is open, it is necessary to press on the push-button B in Fig. 2, which releases the air pressure stored in the tank, and, passing through the distributor, forces one of the pistons down, thereby causing the crankshaft to rotate. The distributor in turn opens the next valve and so on, rapidly turning the engine until the latter takes up its cycle of explosion. The pressure of the knob, besides releasing the compressed air from the tank, opens the valves that are fed from the distributor. These can be clearly seen in Fig. 1.

Goodhart Starter—Another recent example along the same lines, this time from across the water, is known as the Goodhart engine starter. The device consists of a helical spring mounted on the clutch shaft, Fig. 3. This spring is wound up by the motor, which it subsequently restarts by being released. The shaft AB is cut in two and the half carrying the clutch is keyed to the boss A1, having dogs, which engage with others upon a ring C. This ring has a peripheral ratchet wheel, which can be slid along the drum D through the medium of keys D1, thereby sliding the teeth of the wheel in and out of engagement with the pawl F mounted upon some fixed part of the chassis. The drum D contains a flat helical spring, the outer end of which is fixed thereto and the inner end to a flange B1, which is keyed to the transmission half of the clutch shaft.

The drum also carries two dogs D2, which allow of a little less than one revolution being made before they bring up against two similar dogs B2, on the flange B1. The loss of the flange

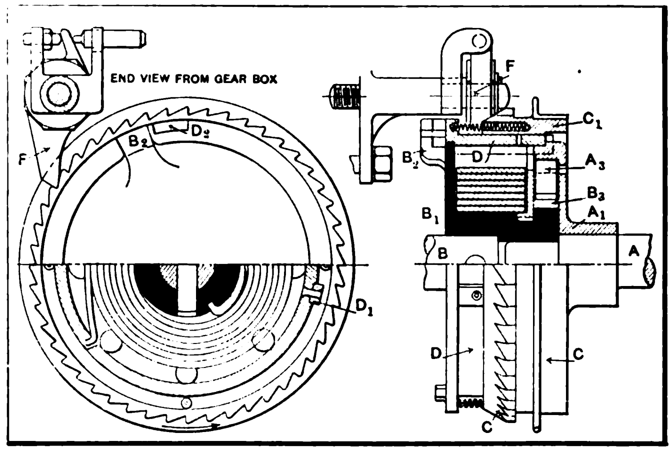

Fig. 3—Sectional view of Goodhart engine starter, an English invention

B carries a ratchet B3, which is held by a pawl A3 fixed to A1. When a load is put upon the clutch shaft through the engine driving the car the drum, with one end of the spring attached to it, rotates and winds up the spring until the dogs D2 and B2 come into contact with one another, when the whole device, being solid, transmits the power in the usual way. The spring having thus been wound up, is retained in this condition by the pawl and ratchet B3 and A3. To start the engine a pedal slides the ratchet ring until it engages with the pawl and also causes the dogs C1 and A2 to disengage.

The spring is then free to unwind and rotate the clutch shaft through the medium of the ratchet and pawl B3 and A3. The pedal being released, the ratchet slides back to its normal position and the spring is again wound up as described above. Some tests were carried out under the control of the Royal Automobile Club, which were satisfactory while the motor was warm, but which failed when an attempt was made to start the motor when it was cold after standing all night.

This may have been due to the make of car, which had automatic intake valves and battery ignition. When the engine was warm it was found that the pull of the contrivance was sufficient to cause the engine to make three complete revolutions.

---

To Fly or Not to Fly: That's the Rub—Intermediate forms have wiped out the sharp distinction between monoplanes and biplanes, and the world is returning to its first classification of flying machines—those which fly and those which don't.—*Pierre Maillard.*

Motorphobia or Philanthropy—Switzerland, accused of motorphobia in her somewhat radical road regulations, retorts that it is not motors but motorists she loves less and the plain humans she loves more.

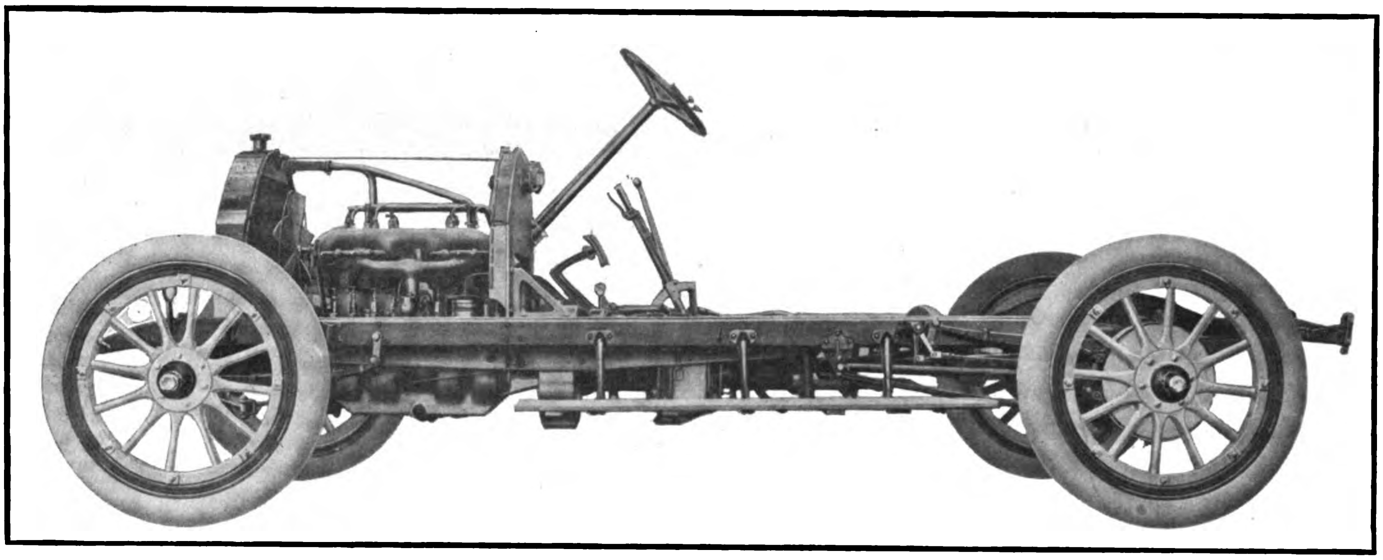

Fig. 1—The standard chassis of the Speedwell line, used with all types of cars

Specifications of the Speedwell

THE chassis used in connection with the 1912 output of the Speedwell Motor Car Company, of Dayton, Ohio, will be fitted with twelve different styles of body. The same chassis is used throughout and is equipped with a standard power plant.

The Speedwell motor is a four-cylinder four-cycle product, with the cylinders cast in pairs The castings are of the L-head type, the valves all being on the left-hand side of the motor and the exhaust and inlet manifolds M and N, Fig. 8, being placed one above the other. The lower manifold N is the inlet. The manifolds are held in place by means of dogs and stud bolts. The waterjackets are cast integrally with the cylinders, but are fitted with removable heads to allow of inspection and cleaning.

The pistons are of gray iron finished from the casting by grinding to a fit and equipped with four piston rings which are hand finished to insure accuracy. This process of manufacture is a longer one than by turning the rings out entirely by machinery, but there is a gain in the fitting of the part when made in this manner.

The valves are interchangeable throughout the motor and are all directly operated off the same camshaft. The valve tappet guides G extend a liberal distance above the crankcase and are detachable by removing the nuts, which are screwed directly into the top of the crankcase. Above the valve tappet guides are the valve rod adjustment nuts, by means of which the valves may be kept properly timed after they are ground or otherwise adjusted. Above the adjusting nuts are the spring seats upon which rest the valve coil springs S. The camshaft is driven through a set of gears at the front end of the motor, the drive passing through an intermediary wheel N, Fig. 6, before being transmitted to the camshaft gear wheel T. This intermediary wheel is the same size as the camshaft wheel, being twice the size of the gear L on the end of the crankshaft.

The remaining wheel O in the timing gearcase is of the same size as the gear on the end of the cranks and actuates the shaft which drives both the magneto M, Fig. 7, and water pump P. This shaft runs along the right-hand side of the motor and drives the fan pulley just after passing through the end bearing of the shaft. Just behind the fan pulley there is a coupling; the shaft then passes to the water pump and fan. The lengths of shaft adjoining the magneto and pump are removable so that either of these parts may be taken out independently of the other, this being effected by means of adjustable companion flanges. The gears which drive these shafts are all of helical cut, a feature which tends to avoid noise.

The crankcase is a two-piece casting of nickel-aluminum alloy, the upper half being entirely separate from the lower. The two cylinder blocks are fastened to the crankcase by means of heavy

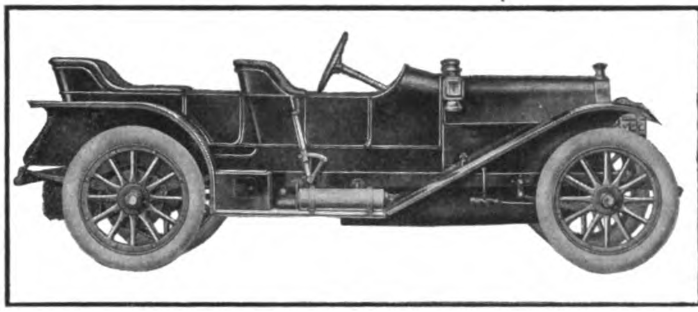

Fig. 4—Showing the Speedwell demi-tonneau

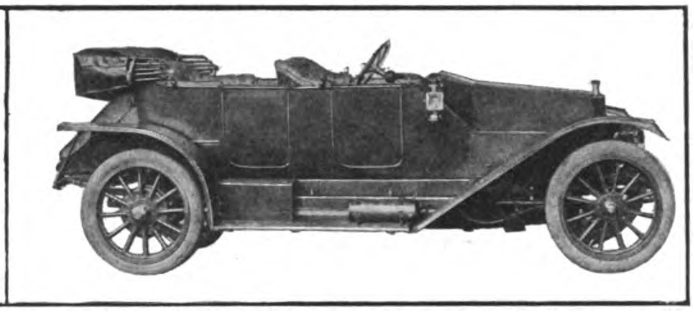

Fig. 5—Speedwell "cruiser," which sells for $3,500

holding down bolts which pass through a broad flange on the base of the cylinder castings and through the crankcase. The casting is so formed that a seating is furnished for each of the valve tappet guide nuts mentioned above, the timing gear casing being also a part of the casting. The cover of the gear housing is removable so that easy inspection of the timing gears is afforded. The motor supporting hangers are cast with the upper part of the crankcase so that the lower half may be dropped entirely by merely removing the bolts which support it and by this means access may be had to the cylinders, pistons, camshafts, crankshaft, connecting rods and wrist-pin bearings.

The crankshaft is of heat-treated alloy steel and is supported upon three plain bearings of good length. The bearings are lined with double white bronze bushings and are located at the ends of the crankshaft and between the two pairs of cylinders. In balancing the crankshaft, the flywheel is bolted thereto and then weighed upon a special instrument made for the purpose.

The lubrication of the motor is effected by means of the splash system. The oil is carried in the lower part of the crankcase, which is divided in such a manner that it consists of two parts. The division is made by a horizontal partition which is placed in the lower half of the crankcase and forms the basis for the troughs used in the splash system as well as the top wall of the oil reservoir. The oil is carried beneath the horizontal partition in the lower half of the crankcase, which has a capacity of about 2 gallons. The oil is supplied to the crankcase reservoir by means of a filler hole F, Fig. 7, on the side of the crankcase. This filler hole is provided with a cap which, when removed, discloses a screen through which the oil is poured when filling the crankcase. The height of the oil in the reservoir is determined by means of a float level gauge on the same side of the motor as the filler hole so that in filling it is not necessary to spill oil on the exterior of the motor, for by watching the gauge it is easy to determine the amount of oil in the crankcase. A gear driven oil pump takes the oil from the base reservoir and leads it to a sight feed which is located on the dash in easy view of the driver. All the oil which passes through the lubricating system of the motor must pass through this sight feed, so that the driver has always an accurate knowledge of the condition of the oil in the motor.

After leaving the sight feed the oil is led to the crankcase through a distributing pipe. The distributing pipe leads to the splash troughs in the upper part of the base casting of the motor.

The motor is cooled by water which is forced through the jackets by a centrifugal pump mounted as described above. The jackets are made of good width and thus aid in an easy circulation. The water intake manifold is on the right-hand side of the motor, the water outlet being at the top of the cylinder castings. The latter consists of a siamesed pipe which runs from the top of the cylinder waterjackets to the top of the radiator, the junction of the two pipes taking place at a point just

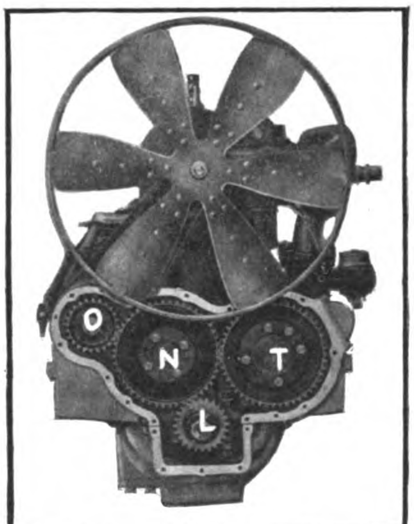

Fig. 6—End view of motor, showing timing gears and fan

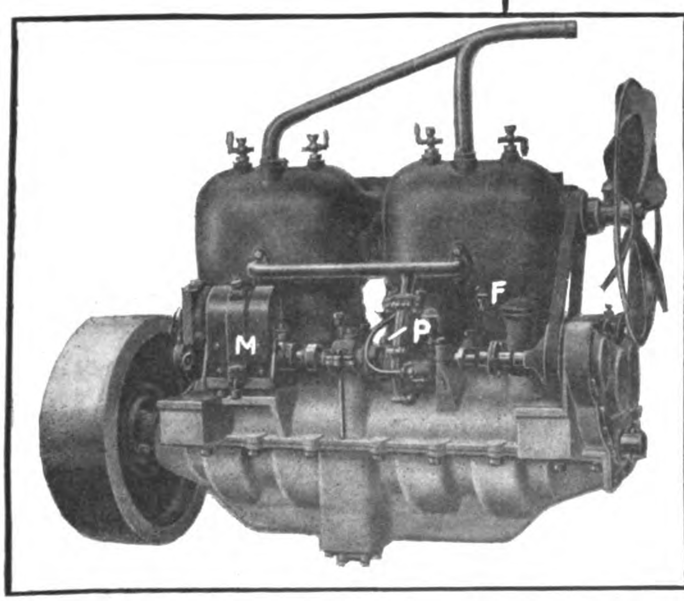

Fig. 7—Magneto side of Speedwell motor

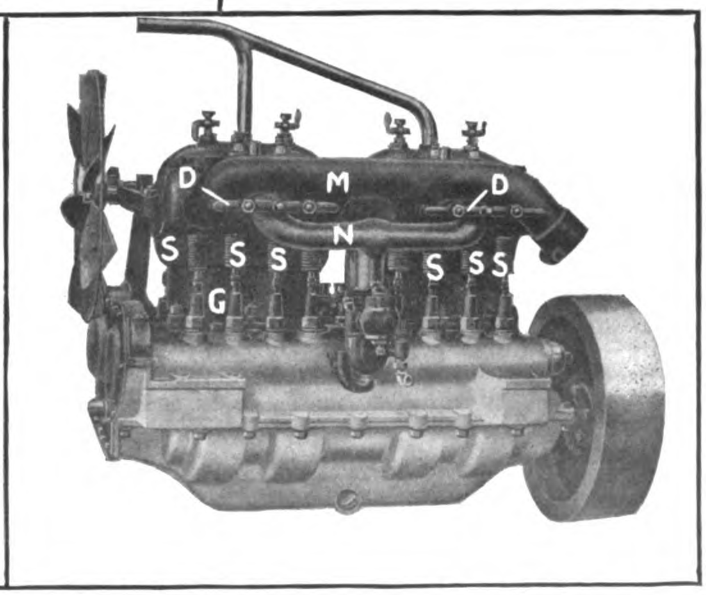

Fig. 8—Showing manifolds and valve actions of the motor

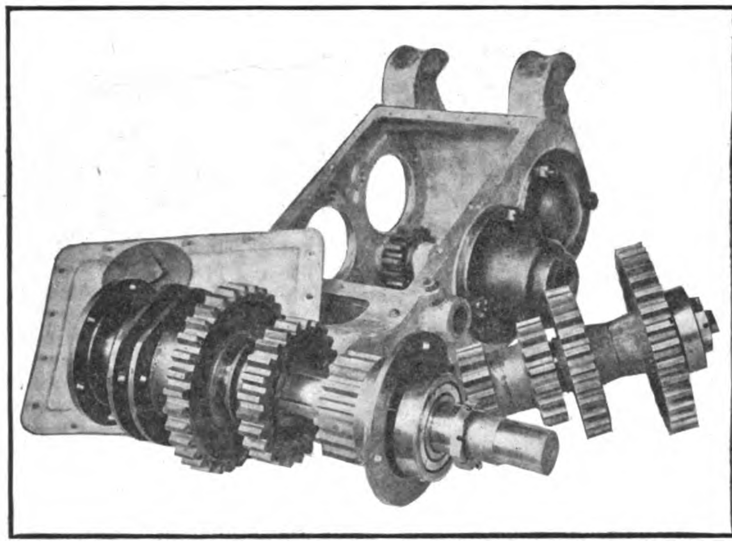

Fig. 9—Disassembly of the gearset

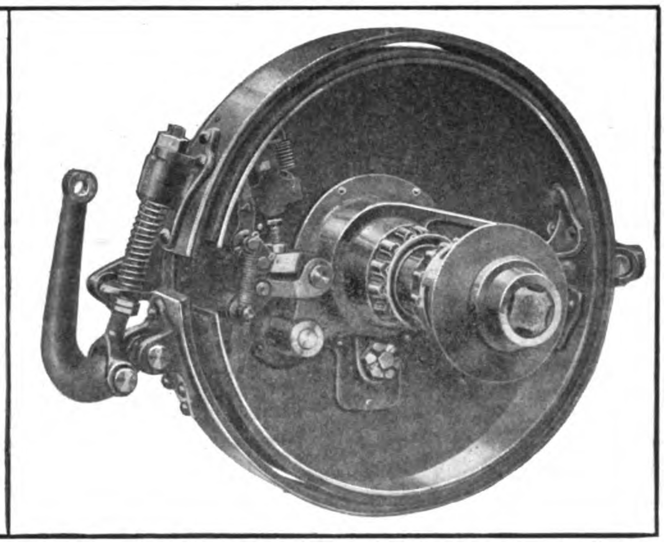

Fig. 10—Showing the brake mechanism

above the center of the foremost pair of cylinders. The radiator is of the Speedwell type and is of cellular construction. A feature of the radiator is that the cells are of square section and that the water circulates in all four sides of each cell. The radiator is cooled by a six-blade fan which is driven by a belt off a pulley located on the pump and magneto shaft. The belt is adjustable so that any stretch may be readily taken up.

The carbureter is hot-water jacketed and is held suspended from the T-shaped inlet manifold. The throttle is augmented by an adjustable cam which controls the opening through which the gasoline passes into the mixing chamber. When the throttle is opened this passage is enlarged. The auxiliary air valve is entirely automatic.

Ignition is accomplished by means of the Bosch dual system. The high-tension magneto is located as has been described. The magneto furnishes the running current while the battery set, which is also provided, furnishes the current for starting the motor. One coil and a single set of spark plugs are employed for both systems. The coil is of the non-vibrating type and is set in the dash so that it is readily accessible from the driver's seat. The appearance presented by the coil is merely that of a circle of 4 inches in diameter. A self-starting button and kick-over switch are fitted on the dash. The timer is not required for this system since it is an integral part of the magneto.

The clutch is of the leather-faced cone type, fitted with a spring engagement so as to insure an easy take-up in starting. The clutch is provided with a ball thrust which is contained in a dust-tight housing. As soon as the clutch is disengaged a clutch brake stops it from rotating. This will tend to produce silence in the changing of gears. The clutch is held to its work by means of a heavy spring which is released through the action of a yoke which in turn acts on a ball thrust ring. A universal joint is provided between the clutch and the gearset so as to provide for any disalignment due to inequalities in the road or other causes. The universal joint and thrust bearing are both enclosed and packed tightly in grease to keep them well lubricated.

The gearset is mounted on a subframe in the center of the chassis and is accessible for adjustment or lubrication by means of a removable cover which can be detached by removing the floor board above it. One of the changes incorporated in the new models is in the gearset, as the size of the gears has been increased and the shafts have been made heavier. The shafts are of nickel steel heat treated, while the gears are of vanadium. The shafts are mounted on annular bearings which are capable of considerable wear before a change in adjustment is necessary. The change gear arrangement provides for three forward and one reverse speeds, the changes being made by means of a hand lever in the usual H-slotted quadrant. By this method the selective type of gearing is used; that is, any desired change may be made without passing through the other speeds. The gearset shafting runs in oil and is closed by means of stuffing boxes which prevent a leakage of the lubricant.

The propeller shaft is provided with universal joints at either end which take up the differences in alignment. The shaft is forged directly with the cross-pieces of the universal joints so that the

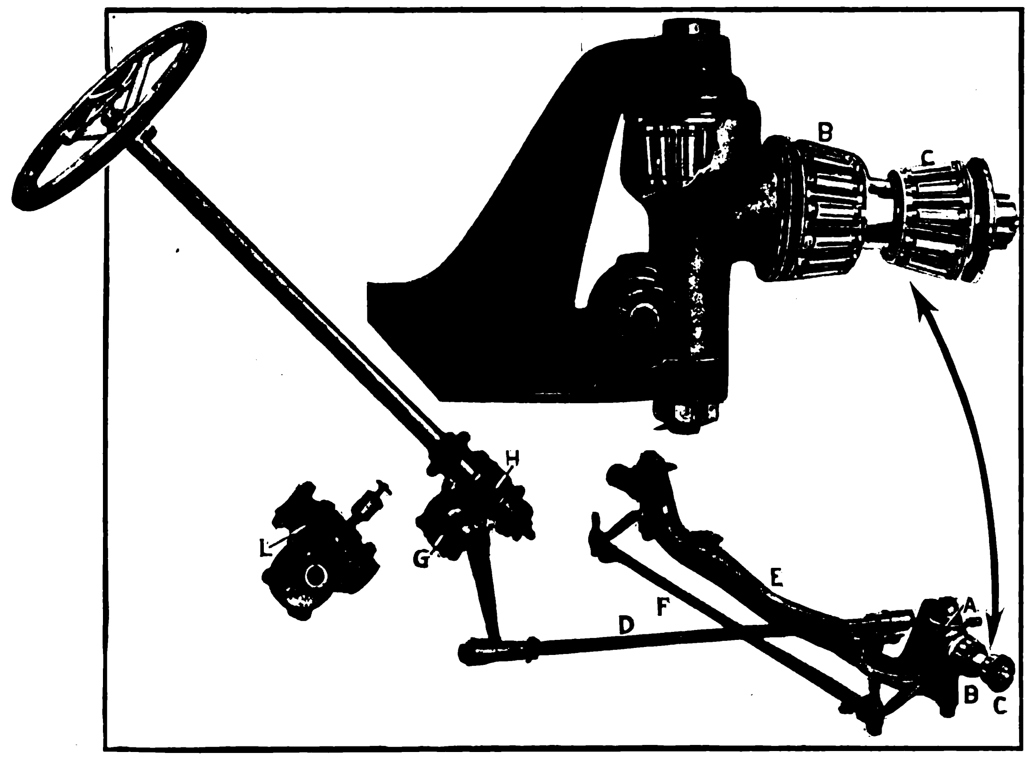

Fig. 11—View of front axle and steering gear with an enlargement of the knuckle

whole integral piece can be given the same degree of heat treatment. An object in the design of the chassis that is worth mention is that when the car is carrying passengers the springs will be deflected to just such a degree that the drive will be very nearly a straight line. This will save a loss in the driving efficiency. The universal joints on the propeller shaft are enclosed in grease-tight casings which protect them very effectively against any accidental derangement.

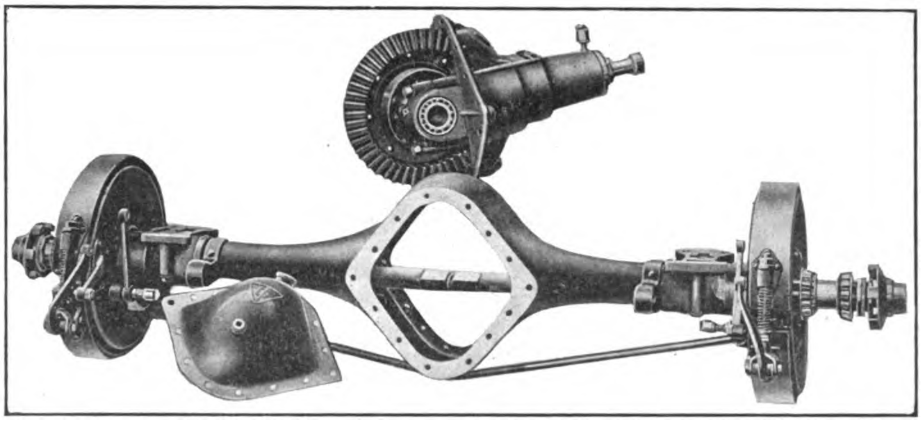

Fig. 12—Rear axle with differential removed. Note squared ends of live axles

The rear axle is of the floating type, the casing containing the differential and live axle being all in one piece, with an inspection cover bolted over the differential. The differential, large and small bevel gears and their bearings may be lifted directly out of the axle housing if it is desired without disturbing any adjustments. All moving parts of the differential and rear axle run on Timken roller bearings. Strut rods are fitted on the axle and are fastened to the frame by ball joints to relieve the frame of driving shocks, while the torque strains are taken up by a torque rod which is suspended between the spring buffers.

The front axle is a drop forging of I-section, the spring seats being forged integrally with the rest of the axle. The front axle E and steering gear are shown in Fig. 11. The steering pivot works on a Timken roller bearing A, which is made large enough to carry the weight of the car. This bearing is shown enlarged in the illustration, as are also the two wheel bearings B and C. The connecting rod F between the two wheels is placed behind the rear axle and the reach rod D which connects the front wheels to the steering gear is placed above the axle.

The steering is effected by an irreversible worm and gear G of vanadium steel which is enclosed in a tubular casing L. Jars and strains are removed from the steering gear by cushion springs which are fitted in the reach rod. The steering wheel is 18 inches in diameter, being of Circassian walnut with an aluminum center. The spark and throttle levers are mounted above the wheel.

Motor and transmission are supported by a subframe which is hot riveted to the main frame and stiffened by means of gusset plates. The springs are semi-elliptic front and rear, being 2 1-4 inches wide and 40 inches long in front and 56 inches in rear.

The wheels are of the artillery type and fitted with Firestone Q. D. rims, except that in the Model H roadster Goodyear rims are substituted. All five-passenger models are fitted with 36 x 4-inch tires, while the seven-passenger models have 36 x 4 1-2-inch tires. The rear wheels are equipped with foot and hand brakes, as shown in Fig. 10. The service or foot brakes and the hand emergency brakes are each furnished with equalizers and are of the expanding and contracting types.

The bodies provided with the standard chassis, are of twelve types and consist of a semi-racer roadster, an open-pony tonneau, five-passenger touring car, close-coupled five-passenger car, four-passenger torpedo, four-passenger semi-racer, three-passenger duck boat, fore-door five-passenger touring car, seven-passenger touring car, seven-passenger limousine and a four-passenger cruiser.

Digest of the Leading Foreign Papers

DEFECTS IN CASEHARDENING WORK are attributable either to the process of cementation or to that of hardening. Those due to errors in the cementation may be (1) deformations, (2) failure to cement, (3) cementing where none is wanted, (4) irregularity of penetration, (5) excess of carbon percentage in the cemented shell, which causes accidents in the hardening, and (6) spots in the metal. The defects which the hardening process may produce are (1) deformations, (2) irregularities in hardness, (3) cracks and (4) spots.

Defects which may be due to other causes or which are not developed until the casehardening piece is taken into use are (1) partial or complete lack of hardness, (2) brittleness of the core, (3) brittleness of the shell (the same breaking off), (4) rupture of the shell and (5) deformations which are developed during use.

Deformations in cementing may be due to placing the piece in its box in such a position that its own weight will bend it when hot. More frequently it is due to twisted grain or fibre of the metal (*écrouissage*). The piece is usually made from rolled or drawn stock or it has been pressed or stamped and its molecular structure is more or less upset or misshapen. To avoid this trouble the stock, before it is machined, should be brought to a uniform heat 50 degrees higher than the critical temperature (which is about 900 degrees centigrade for soft casehardening stock), and should be allowed to cool slowly, especially if the steel is rich in nickel (5 per cent. to 6 per cent.), as otherwise martensite is likely to form, rendering the stock hard to work. At all events the hardening department should not accept deformed pieces, since it is relatively easy to redress pieces which have only been cemented. After all, however, a deformation which has been removed may reappear in the heat before quenching.

Failure to cement is rare and always due to poor workmanship. As has been proved, all steels except gamma steels (of high nickel and manganese) harden by cementation followed by bath.

Both failure to cement and failure to protect certain portions against cementation are discovered only after the quenching, by filing (or the scleroscope).

Irregularities in penetration come from poor distribution and packing of the cementation powder or compound, or from lack of uniformity in the fire. Irregularity in the carbon content of an otherwise equable shell is due to too high or too low heat, to wrong timing of the heat or to a poor cementation compound; rarely to an excess of silicon in the steel.

Too high carbon content in the outer shell is much to be feared. A cement too active, excessive temperature or prolonged exposure to the heat are the causes, and steels of medium carbon are more subject to this trouble than mild steels.

Spots in the metal are usually due to a silicious filler-earth or to a wet cementing compound.

No sure remedy has been devised against deformations resulting from the quenching, though Breshaw has shown that in the case of certain high-carbon steels a double heating reduces the deformation. Irregularity in the hardness, whether it is shown in each piece or by comparison among several pieces which should be of the same hardness, may be due to faults in cementation or to quenching at a wrong temperature (750 degrees C. is right), but it may also be due to loss of carbon in the heating before the bath, and the latter is the more frequent cause. If the atmosphere is oxidizing, which is the rule in furnaces heated by direct coal fire and common in gas furnaces, though perhaps only caused by the repeated opening of the furnace door, a decarbonization takes place which easilly penetrates 1-10 mm. to 1-5 mm. into the shell and is sufficient to reduce the hardness of the finished piece greatly. Cracks in casehardened pieces are seldom due to the treatment, but usually may be traced to flaws in the billets. Spots appearing after the quenching are due to exposure to oxidation.—From treatise on casehardening by Léon Guillet in *Le Génie Civil,* July 29 and August 5.

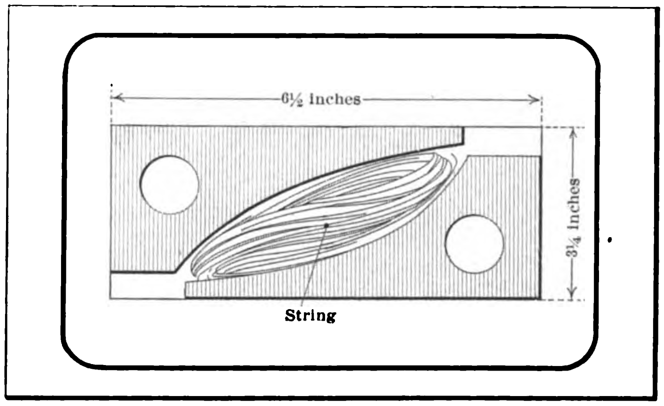
Laboratory and shop inspection of case-hardening work should be distinct and separate. Only the largest establishments can have a laboratory personnel whose function it is to supervise the reception of raw material or to check off materials at the steel works and afterwards verify the partial shipments. Where there is a laboratory force, it should take a certain number of samples from a lot of casehardened pieces and should try them by chemical analysis, especially for carbon content in the shell, and this content should not exceed 1.2 per cent. Further, a micrographic examination should show martensite at the center of the hardened piece, and even finely divided pearlite if the piece has been subjected to the double quenching process, but martensite and ferrite if it has been quenched at 750 degrees only. In large pieces some osmondite should appear. The shell should always be formed of very fine martensite without cementite. Examination of an annealed piece also gives valuable information, showing the thickness and regularity of the cemented layer and the carbon content at the surface, but it must be remembered that, during this annealing, carbon migrates from the periphery toward the center, lowering the carbon content at the surface.

The laboratory force should also look into the matter of possible brittleness of the core. In the majority of shops results are judged by filing with regard to hardness and from the grain of a fracture with regard to brittleness. But these tests are rudimentary and cannot be connected in figures. The grain gives occasion for most erroneous inferences. The result depends mostly upon the method used for producing the fracture and upon the thickness of the piece. As the author has shown (and illustrations are presented of the fractured pieces), the same casehardened bar fractured in several places a few centimeters apart shows a fine grain and a fibrous core wherever it has been broken by many light blows, but a very coarse grain where it has been broken by one severe blow. No importance should be attached to coarseness of grain, unless fractures are produced in a perfectly constant and predetermined fashion and unless it is very well known what kind of fracture each kind of piece should produce under these circumstances. In reality there is only one method for testing brittleness, which is by the notched bar and impact test, as prescribed in the main features by the congress of Copenhagen (1910), and the details of this method are in need of further precisioning. (The author here seems to take distance from those scientists who hold that the relations between tensile strength and the resistance to crushing. in test pieces of prescribed dimensions, always give an exact measure of brittleness).

The methods of shop inspection and control are of wider application and, therefore, perhaps of greater importance than those to be practiced at the laboratory. (1) All pieces arriving at the shop for treatment should be tried for hardness with reference to its uniformity. To this end the Brinell rating should be determined by a steel ball pressure apparatus which should be suitable for receiving pieces of greatly varying size and shape. One of the new Cail apparatus serves the purpose, or else another model which is used at the Derihon factories at Loucin-les-Liège and which the author has reproduced at the Dion-Bouton factories. It consists in a lever carrying the steel ball at one point and a weight at the end of the lever. All pieces intended for treatment should, in the author's opinion, be passed under this apparatus, and one workman can perform this at a shop turning out 250 to 300 casehardened pieces per day. (2) The shop inspection of the cementation process is best served by placing a test piece of the same steel which is used for the work at some certain point of each box—preferably at the middle of it—and breaking this piece after quenching it at 750 degrees. After some experience this will give an approximate idea of the thickness of the shell in other pieces. (3) Shop inspection of hardness after quenching. Until recently it has not been possible to measure hardness. By filing it was only estimated, and the Martens sclerometer is only a laboratory instrument. In practice the scleroscope is now of the greatest utility in casehardening shops, as Portevin and Berjot have shown in *Revue de Métallurgie* for January, 1910. The height to which a steel ball, or rather a little hammer with a diamond point, rebounds from the hardened piece when allowed to drop from the top of scleroscope furnishes a practical means for actually measuring hardness in all its degrees, even if the rebound is to some extent a function of the mass of the test piece.

In brief, shop inspection of casehardening work involves the purchase of one Birnell apparatus and one scleroscope, which is not a highly expensive equipment, while the results are of the highest interest for securing the uniformity of work.—From treatise on casehardening by Léon Guillet in *Le Génie Civil,* July 29 and August 5.

A USEFUL ADDITION TO THE AUTOMOBILIST'S TOOL-BOX—It is sometimes difficult to find a couple of stones of suitable size to chock under the wheels, when a car is left standing at the side of a steep road, and the brake adjustment is not always right for locking the wheels when the driver's foot or hand is not on the pedal or lever. With this difficulty in mind a motorist tells of an arrangement he has made. He has in his tool



Handy tool-box adjunct—chocks to block the wheels, and how to carry them

box two chocks or wedges made of pine wood and packed as shown in the illustration, a large skein of tarred string or cord acting as wedge to press the chocks against the sides of a little kit in which they are kept, thus preventing all rattling. And the string comes very handy for bandaging a sick tire or for wrapping any kind of a package. The two holes in the chocks make it easier to take the contents out of the kit, and also may serve as receptacles for two little rolls of adhesive tape.—*Automobile-Aviation,* September 14.

OKNOF, of the metallurgical laboratory at the Polytechnical Institute of St. Petersburg, details a series of experiments, accompanied with large micrographic plates, in which he comes to the result, among others, that, 1, pearlite consists of curved lamellæ of cementite imbedded in the mass of ferrite, and, 2, martensite consists of straight, flat, but not needleshaped, crystals.—*Métallurgie* (Halle a. d. Saale), Sept. 8.

Harking Back a Decade

TEN years ago this week *The Motor Review* contained notice of the following happenings:

A 9-horsepower Gasmobile, driven by William Walters and carrying Eddie Bald and Sam Brock, broke the record for the run between Buffalo and Niagara Falls by 2 minutes. The car made the distance in 38 minutes, some of the miles being turned in 1:30.

W. C. Janes has purchased the Buffalo branch of the Locomobile.

The capital stock of the newly formed Stearns Automobile Company has been offered to the public at Syracuse, N. Y. The common issue was offered at $5.25 a share, par value $25.

The automobile trade of Philadelphia has formed a permanent organization. The first act of the association was to postpone the show dates until early in 1902.

At Pittsburgh, for the first time, automobiles formed a feature of the industrial displays at the annual exposition.

Floor plans of the Chicago Coliseum, arranged for the show next March, indicate that the demonstrating track around the exhibits will be used again. This feature has been dropped from the New York shows.

Rumors are again in circulation of a merger of the tire-making interests at Akron. August Belmont and Charles R. Flint, who were active in forming the United States Steel Corporation, are said to be engineering the plan.

If some of the many thousands of good mechanics who are struggling to manufacture complete cars would turn their attention to the operation of storage and repair stations the automobile field would be cleared of many so-called manufacturers who are really only experimenters.—Editorial.

Three out of twenty cars that started in the Chicago-Buffalo tour reached the goal. The difficulty in touring is not to make the cars go over the road, but to make them go together. Pleasure on the move is hard to gain for a number of people collectively. The fact that only three cars finished is a reflection neither upon the cars nor the drivers.—Editorial.

A pneumatic self-starter for automobiles is the leading patent treated this week. Auxiliary valve gearing to supply compressed air is the feature. After starting it is necessary to shift the valve gear to supply the gasoline mixture. Patent No. 683,459.

The Shelby Steel Tube Company, of Greenville, O., announces that it will enlarge its plant materially. It is the intention of the company to become the largest seamless, cold-drawn tube plant in the country. A billet-piercing plant is to be installed by the company.

Pittsburgh police have taken a sharp interest in the speed limit recently. The legal rate is 12 miles an hour. Last Tuesday a well-known chauffeur was halted by an officer but he proved such a convincing talker that he was soon allowed to steam away.

The Stearns Steam Carriage Company will send seven types of carriages to be exhibited at the Boston show this Fall. The cars are all of 1902 model.

Six Locomobiles will act in place of horses as conveyances for the Grand Marshal and his aides at the forthcoming bi-centennial parade at Yale.

The race meeting of the Rhode Island Automobile Club will be held at Providence, October 17, 1901, and there are a large number of entries in the various events.

Letters Answered and Discussed

Concerning Engine Design

Editor THE AUTOMOBILE:

[2,862]—I would greatly appreciate it if you would give some information regarding gasoline engine design.

1. What should be the length of the piston used in connection with an engine having a bore of 4 inches?

2. What should be the diameter of the piston pin and what is the best location for it? How should it be fastened to prevent endwise movement?

3. How is the side-thrust on the cylinder walls calculated?

New York City. ADOLPH KLINE.

Referring to the sketch, Fig. 1, the dimensions of the various parts of the piston will be seen. The bearing surface of the piston for an engine of 4-inch bore should be about 4 1-8 inches in length. The wrist-pin may be located very nearly at the center of the piston or it may be located at the exact center and should be fastened by a set bolt and lock nut as shown. The set bolt may be a 3-8-inch bolt. The position of the piston rings is arbitrary to a great extent and the dimensions as given in the illustration need not be rigidly adhered to.

The side thrust on the cylinder walls is calculated by taking the thrust on the top of the piston and multiplying it by the tangent of the angle which the connecting rod makes with the axis of the cylinder. Since the tangent of this angle is a maximum when the crank makes an angle of 90 degrees with the cylinder axis the side thrust will be about a maximum at this

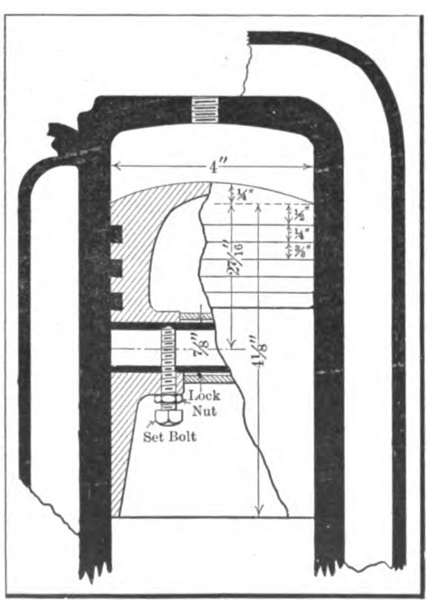


Fig. 1—Showing a section through a piston for a motor of 4 inches bore

The Editor invites subscribers to communicate their automobile troubles and personal experiences, stating them clearly on one side of the paper. If the nature of the case permits, send a sketch, even if it be rough, in order to assist to a clearer understanding. Each communication will receive attention in the order of its receipt, if the writer's signature and address accompany it as an evidence of good faith. If the writer objects to the publication of his name, he may add a nom de plume.

My Best Repair

Temporary automobile repairs made by the driver or owner while on the road and permanent repairs made in the garage after the run is over, are interesting to all automobile owners.

Every driver at one time or another gets up against it. Something breaks or gets out of order on the road—a stop has to be made and some repair effected.

It may be a spring leaf has broken; a shackle bolt or strap may break; a steering tie rod is bent; the car skids into a curb and bends a steering arm or the starting crank; a throttle or magneto connection breaks owing to vibration; a radiator leak is started by a stone or some other means; a leak in the gasoline tank is discovered; there is a small hole in the gasoline feed line; a brake facing may burn out; a brake connection breaks; a front axle gets slightly sprung; a clutch starts slipping, or any one of a thousand things may happen.

Every automobile owner is interested in knowing how repairs have been made, how long it took to make them, how much they cost, and by whom they were made. All this information broadens the knowledge of the automobile owner and so helps the industry.

Thousands of car owners who are readers of THE AUTOMOBILE, *have had experiences of this nature and have made a temporary roadside repair—a permanent cure at the garage. We want you to write in simple language in a letter what repair of this nature you have had to make, how you made it, how long it took you and how much it cost.*

You can make with your lead pencil one or two rough sketches indicating the broken or damaged part and showing how the repair was made.

We are going to publish these repair letters from week to week in these columns. Every reader should send in one experience or repair and how accomplished.

Some have experiences with short circuits, adjusting carbureters, motor knocks, hard starting, noisy timing gears, etc. Information on how these were discovered or rectified are equally interesting.

The experience of each reader is interesting to every other reader. To you, some of your repairs or experiences may be commonplace, but to owners of automobiles with less experience they are most interesting.

Analyze your past experiences and send in one or two of them.

Give your name and address, legibly written. If you do not want your name to appear, make use of a nom de plume.

Editor THE AUTOMOBILE.

point. Since the tangent of the angle used in the calculation is, at this point, the length of crank divided by the connecting rod, the calculation is simply one of multiplying the thrust upon the top of the piston by this fraction. At this point the thrust will not exceed 300 pounds which may be taken for a safe calculation. Taking an example to make the process perfectly clear, a connecting rod 12 inches in length may be assumed, and the crank which will equal one-half the stroke may be taken as 2 1-2 inches. The side thrust will then equal $\frac{300 \times 2\frac{1}{2}}{12} = 62\frac{1}{2}$ pounds. The explosion pressure is all that has to be

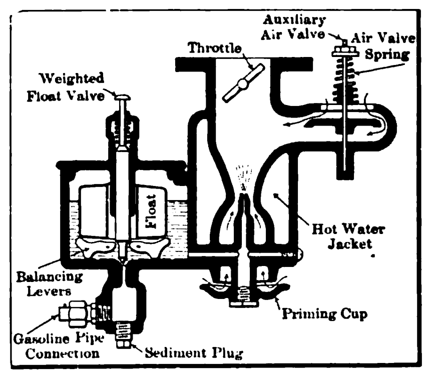

Fig. 2—Section through carbureter with eccentric float

reckoned with in designing the combustion space.

Wants Points of Adjustment

Editor THE AUTOMOBILE:

[2,863]—I followed with great interest your directions as to the manner of adjusting the carbureter. I wish you would point out the positions of the various fixtures for adjusting the gasoline, air, etc., on different types of carbureters.

Plattsburgh, N. Y. AMATEUR.

The adjusting devices on all the carbureters are on the same principle and by the illustration of two of the common types it would be a simple matter to perform the adjustments on any and to locate the points of adjustment. Fig. 2 shows a type of carbureter in which the float is not concentric with the spray nozzle, while Fig. 3 shows a carbureter with the spray nozzle and float concentric. In the latter illustration the needle valve is adjusted at A, the auxiliary air valve at C, by either increasing or decreasing the tension on the spring B. The gasoline inlet is regulated at D, the main air valve at E and the drain cock is located at F. By a comparison with the type depicted in Fig. 2 it is seen that the principles of adjustment are the same.

One Cylinder Dead

Editor The Automobile:

[2,864]—Since you have a page of your magazine devoted to the troubles of your subscribers I am going to take advantage of that fact and ask you to help me out of my trouble.

I have a car which is equipped with a four-cylinder motor. In one of the four cylinders I can get no explosion, and after having run the engine for a time the cylinder which does not fire contains quite an amount of oil. The electrical plant seems to be all right, including battery, wiring, magneto and spark plugs.

I have to prime the motor before it will start and, after priming it have to turn it over several times before getting an explosion. On the first explosion the engine will backfire and then will run all right except that the one cylinder will be dead.

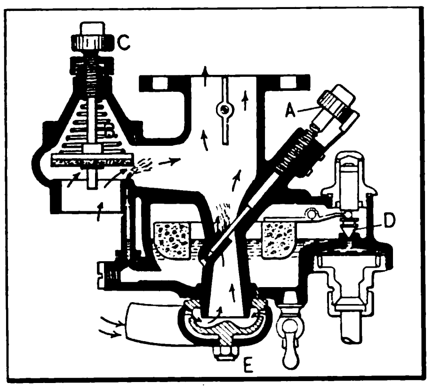

Fig. 3—Section through carbureter with concentric float

Would you kindly let me know what could be the matter?

M. W. Van Amber.

Castorland, N. Y.

Since the other cylinders fire without trouble after the engine is started the trouble will be of such a nature that it is confined to the one cylinder. This eliminates carbureter and magneto adjustments. The only parts of the ignition system which could affect but one cylinder are the spark plugs and the timer; the spark plugs may be eliminated by taking a plug out of one of the cylinders that does fire and trying it in the dead cylinder. The timer may form a perfect connection with all but the point which corresponds to the defective cylinder. Examine the contact points to determine if they are clean or whether the rotor shaft is eccentric and hence misses one of the points altogether. This will eliminate the ignition system.

The search should then turn to the valves. Try the compression of the defective cylinder and notice whether it is leaky. If so, the trouble will be found to be in a pitted, cracked or very dirty valve. If dirt lodges beneath the exhaust valve it will prevent its closing. If the compression is leaky and the valves are in perfect condition the fault lies in a cracked cylinder or in some other cause of leakage between the cylinder wall and jacket. A new cylinder will be required in this case or perhaps the damage may be repaired by some welding process.

The backfiring in starting the motor is due very likely to the fact that when you prime the motor you give it too much gasoline, unless the compression is leaky in these cylinders too which might be the primary cause of the trouble. It is very natural that the dead cylinder would accumulate a quantity of lubricating oil after the motor has been run for a length of time, as it will work its way up from the crankcase.

Wants More Power

Editor The Automobile:

[2,865]—I have a car which I have changed from a touring car to a runabout, the engine having a bore of 3 inches and a stroke of 5 1-2 inches. The exhaust valves are on the left-hand side of the motor and the inlet valves are overhead. The driving gear ratio is 2 2-3 to 1 with 36-inch wheels. Can you suggest a way to get more speed out of the engine?

If I advance my valve timing do I have to have different shaped cams? I am told that I would have to get cams made which would hold the valves open longer. The engine has all the power I need but will not turn over more than 1,300 revolutions per minute. D. B. Blaisdell.

New York City.

The timing diagram illustrated in these columns in the issue of July 20 will give a valve timing which should give the engine a maximum flexibility. If the cams fitted now are not of correct shape to hold the valves open for the period required they will have to be changed for new ones. The exhaust valves are held open for 225 degrees of the crank circle while the inlet valves are held open during a period of 200 degrees.

At 1,300 revolutions per minute the maximum speed attainable with the gear ratio specified would be 52 miles an hour which should be improved by a better timing of the valves.

Has Carbureter Troubles

Editor The Automobile:

[2,866]—After going through a period of tinkering and experimenting on my carbureter I at last conceived the idea of appealing to The Automobile for advice. I intend buying a good carbureter and before purchasing wish to become acquainted with the following points:

1. What are the requirements of an ideal carbureter?

2. Is there a carbureter which offers but a negligible resistance to the ingoing air no matter whether the engine is going fast or slow?

3. Does the increased resistance of the air decrease the power of the engine? I find that if the carbureter is regulated for high speed it is not adjusted correctly for low speed. Wm. Polacheck.

Milwaukee, Wis.

1. The ideal carbureter would furnish a perfect mixture in all senses of the word at all engine speeds and under all conditions of atmospheric humidity.

2. The resistance offered to the incoming air by the carbureter passages is negligible in any of the modern carbureters.

3. The horsepower expended in drawing the air into the mixing chamber is so small that it is not worth attention in figuring the efficiency of the motor.

Has Leaky Tire

Editor The Automobile:

[2,867]—I have a slow puncture in the inner tube and I cannot locate it by listening for a leak, and I would like to know how it is possible to determine the leads in inner tubes when they are so small as to be invisible.

If the tire is porous will it hold the air for a time and then allow it to leak out of the inner tube or will there be a continuous leak? Chas. Cammon.

Burlington, Vt.

The tires are easily tested by placing them when inflated in a deep pan of water such as is shown in Fig. 4. It is a very good plan to hang the tire above the pan as shown and to slowly turn it about. The presence of bubbles will indicate a leak. If the entire surface of the tire is covered with bubbles it will indicate a porous condition of the tire. When a tire is porous the leak will be continuous, the tire not being able to hold the air it contains for any time.

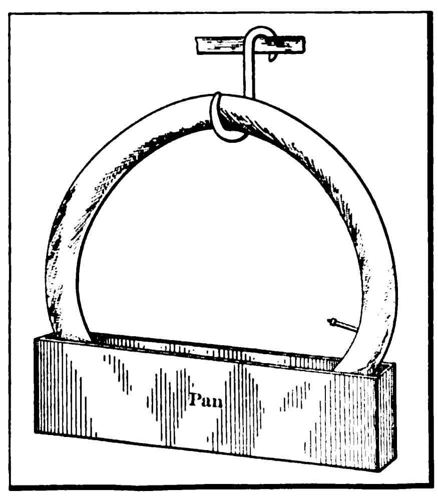

Fig. 4—Method of supporting tire when testing for leaks

Little Bits of Motor Wisdom

Pertinent Pointers for Repairman and Driver

SPRINGS MUST BE CAREFULLY FASTENED—A chassis spring can attain the height of its usefulness and efficiency only when it is fastened in the proper manner. The object of springs is to increase the comfort of riding by arresting shocks which may be transmitted from the road to the body of the car through the chassis. Hence the springs are inserted between the body and the chassis in order to absorb these shocks. Shocks are caused by rapid changes of condition; that is, the rapid arresting of motion or the rapid starting of a stationary body. Hence if the car is started in a downward direction by falling into the small irregularities of the road, instead of being brought to rest with a jar, the shock will be absorbed to a large degree by the springs, which will bring the body of the car slowly to rest. When the wheels of the vehicle pass over an obstruction or sink into a hollow of the road, they alternately expand and compress the springs so that very little of the shock is felt by the passengers.

The three most common springs used in modern automobile body work are the elliptic, three-quarter-elliptic and the semi-elliptic. The first variety, the elliptic, have

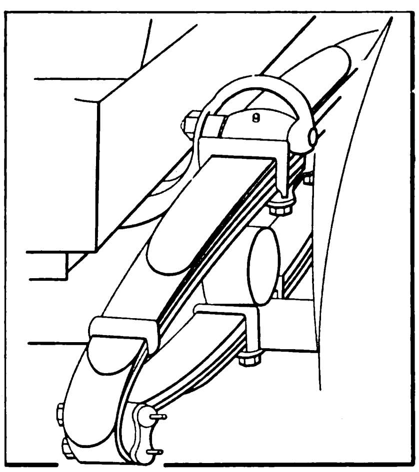

Fig. 1—Showing method of fastening scroll elliptic spring

the halves each a semi-elliptic, fastened together at the ends so that an ellipse is built up. The fastening is generally by means of bolts which pass through the spring ends; the upper and lower halves are connected at the center of their lengths to the frame and axle respectively by means of bolts or clips. These bolts and clips should be fastened in such a way that they do not interfere with the motion of the leaves of the spring, nor should they weaken the spring at the point of application.

The leaves of the springs, which are built up in the manner of those mentioned above, slide over one another as the spring is compressed or expanded. In the elliptic type the spring is elongated under the influence of a load; that is, the members of the spring become more nearly straight as the curvature is reduced. Since the curvature is reduced, each leaf of the spring attains a greater over-all length, and hence the ends of each leaf must slip over the leaf below. It is evident that the springs must not be fastened at any point which will interfere with this motion; therefore they can only be attached rigidly at the center of their length, since this point does not change relatively to the center of the length of any of the other leaves no matter how the spring is compressed or allowed to expand.

Some of the methods of making this fastening are depicted in Figs. 1, 2 and 3. In Fig. 1 a variation of the elliptic type of spring, known as the scroll elliptic, is shown. This spring consists of two members joined by shackles, the top half being a scroll and the lower half a semi-elliptic. The method of joining this spring to the axle and frame may be seen in this illustration. The fastening consists of two clips of inverted U shape, the ends of which pass through a flange of the frame beneath the spring. This is similar in many respects to the method illustrated in Fig. 2. In this case the inverted U clips are used as shown in Fig. 1, and besides this an additional clip is used between the two U clips, consisting of a plate with two bolts passing through it and also through the holding flange.

In Fig. 3 another method of fastening the spring is shown, a special bracket being employed, in this case consisting of two struts and a flange plate through which the bolts pass. The dotted lines indicate a plate which has been removed in order to show the supporting bracket.

The two other springs described, the semi-elliptic and the three-quarter elliptic, are, as suggested by their names, either a half-ellipse or a half-ellipse with a quarter-ellipse added. They are fastened in the same manner at the bottom as the elliptic, the difference being in the manner of supporting the top or frame joint. They are usually held by shackles which are supported by the frame, and in the case of the three-quarter elliptic springs the end of the quarter-ellipse rests upon a platform.

The principal point to observe in fastening the springs is that nothing is done to weaken the spring by piercing it with holes of a dangerous diameter or by cutting it in any way. It must be remembered that the greatest strain on the spring is at the point at which it supports the weight, in the great majority of cases, since this occurs at

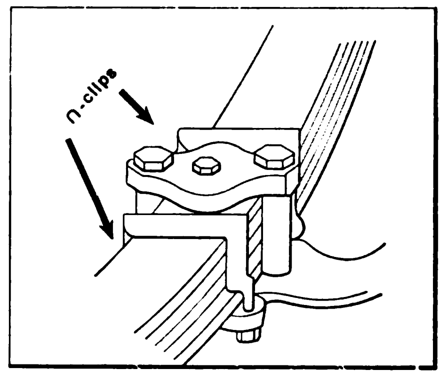

Fig. 2—Illustrating the inverted U-clips employed in holding spring

the center of the spring, and as the fastening is also at that point great care must be taken that too much material is not cut away in making the fixture.

ADJUSTING VALVE STEMS—As the valves are ground down the valve stems are gradually lowered. The lowering is very slight on each grinding of the valve, as very little material is taken off the surface of the valve at each grinding; but after the valve has been repeatedly reseated the lowering of the valve stem will be so great that it will be necessary to adjust it in order that the lift of the valves will be correct. The space between the valve push rods and stems should be about 1-32 inch and can be determined by inserting a feeler gauge, or if there is no feeler gauge available at the time a piece of cardboard about twice the thickness of the average business card may be employed.

The adjusting nuts are then turned so that the valve stem will have the proper clearance as determined by the gauge or doubled card. After the adjustment is made it should always be checked by determining if the valve remains closed during the period required. This is done by taking a piece of thin paper and inserting it beneath the stem of the valve and the engine turned slowly over through the part of the stroke in which the valve is supposed to remain closed. The paper is frequently moved about during this process and if it is pinched at any time it is a sign that the adjustment is not correct, since the pinching of the paper indicates the point at which the valve starts to open. If the pinching takes place at the proper time for the opening of the valve the closing time should also be noted. This is done in just the opposite manner in which the opening time is determined. The paper is continually pinched by the valve stem until it is time for the valve to close, when the paper should be released. The flywheel is generally marked so that the timing as given by the card test can be checked by this. If it is not marked the position of the crank handle will act as a guide in the matter or the position of the piston may be determined by removing a pet-cock or other fitting from

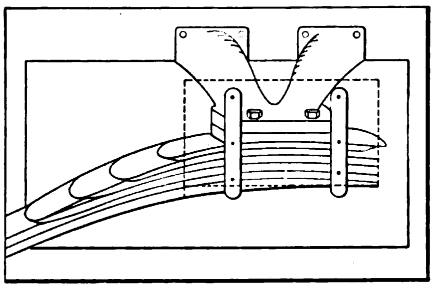

Fig. 3—Method of supporting spring by means of a flanged bracket

the top of the cylinder and inserting a stick which will be lifted by the piston on its travel. It is much better and handier, however, to have the flywheel marked for the opening and closing position of each valve as well as for the upper and lower dead centers of the motor.

The clearance allowed between the valve stem and push rod is very necessary and should not be overlooked in adjusting the valve-lifting mechanism, as the rod will materially expand after the engine has been running for a length of time and has become warmed up. The clearance should not be too great, however, as this would cause the valve to open later than was intended. In the case of the exhaust valve the exploded gases would not have time to be well cleared out of the cylinder, and what remained would dilute the fresh charge to such an extent that the power of the engine would be materially cut down. In the case of an inlet valve the opening of the valve would be delayed and the required weight of charge would not be drawn into the cylinder and the consequence would also be a loss of power.

LUBRICATING SPRINGS—Lubrication is another great factor in the well-being of the spring and is next to the fastening in importance. In absorbing the shocks of the road the different laminations of the spring slide upon each other and in order that they do so in as easy a manner as possible it is necessary that they be well lubricated. There are various means in use of keeping the springs properly greased, most of these consisting of a series of grooves and slots. The oil is generally applied by jacking up the frame of the motor, which will cause the various leaves of the spring to separate, since all the strain is taken off the spring; it is then very easy to cover the leaves with heavy cylinder oil.

The spring bolts and shackles are fitted, as a rule, with grease cups, which should be given a full turn about every 100 miles or once a day. This is a very important operation so far as the noiseless action of the car is concerned. The oil not only insures easy action of the springs but also acts as a rust preventive while the car is not in use.

DO NOT START ON SPARK—A practice which has been in vogue for some time is to open the throttle after the spark has been shut off when stopping the engine, and while it is still running under its own momentum to allow it to draw in a charge of gas in at least one of the cylinders. The spark is then switched on when the driver wishes to start the engine, and in the case of a six-cylinder motor, and very often in a four-cylinder, the piston will be in firing position in one of the cylinders and the motor will start. While this does away with the necessity of cranking the motor, it is not by any means beneficial to it, as the full shock of the explosion is taken up by the motionless parts and the consequent inertia is very great.

The effect of starting upon the spark is very much the same as if the head of the motor were hit a very severe blow with a heavy sledge, muffled in such a way that there is no metallic contact between the cylinder head and the sledge. The jar given to the motor is extremely heavy and is hence to be avoided. The life of a motor which has been continually started upon the spark will be decreased materially as compared with one which is always started by cranking.

KEEPING MAIN BEARINGS COOL—Within the crankcase of the automobile motor there is always present a mist of oil without regard to the system of oiling used. When the splash system of oiling is used this mist assumes the proportions of a spray and pervades the crankcase to such an extent that the actual running temperature of the lower part of the motor is reduced owing to its cooling influence.

The main bearings are often lubricated solely by the oil mist which works its way into the bearings; but this in some cases is not sufficient, a long bearing being apt to overheat. To prevent an occurrence of this nature the bearing casing is often recessed so as to form a sort of cup on the upper half. Holes are then drilled through the upper part of the bearing casing, so that there is a lead from the cup to the bearing through which the oil slowly seeps and distributes itself along the length of the bearing and drips out at the ends. The manner in which these ducts are often cut in the bearing casing is shown in Fig. 4, where the pockets are labeled and the holes from these are shown leading down to the bearing surface.

The main bearings are usually amply supplied where the force-feed system is used, as there is a lead from the pump directly to each of these bearings. The oil is often supplied in a case of this kind under considerable pressure, so that when a hollow crankshaft is employed to distribute the oil the centrifugal force due to the revolving crankshaft may be overcome in forcing the oil into the center of the shaft. The oil lead to the bearing registers with the opening into the crankshaft during a part of each revolution, and during this time the oil is forced into the crankshaft. During the remainder of the time the oil is forced into the bearing itself.

A very common means of lubricating the main bearings which has found considerable favor in recent years is to employ a combination force-feed and splash system. When this method is used there is a lead from the source of oil supply, whether it be from the sight feed or pump, to the main bearings. Thus far the system is the same as the force-feed type, but instead of leading the oil through a hollow crankshaft, or through independent leads to the cylinder walls and connecting rod bearings, the remainder of the lubrication outside of the main bearings is accomplished by the splash system. The oil is allowed to overflow from the main bearings into the splash compartments on either side of the main bearing bridges. Since the oil is supplied to the main bearings in this case very rapidly, the splash troughs are always kept

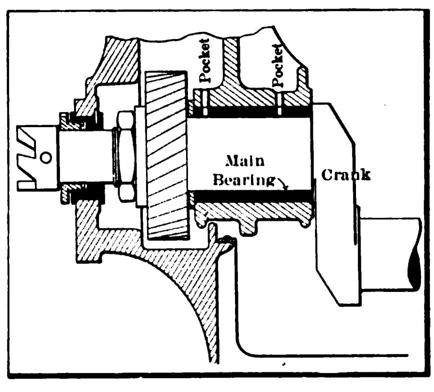

Fig. 4—Showing the oil ducts often cut through the main bearings

full and overflowing, and the main bearings very amply lubricated and adequately cooled. When this method of oiling is employed it should be made a point that the oil is allowed to flow to either end of the bearing so that there is an overflow in either direction. This can be done by having the oil lead directly in the center of the bearing and by suppling an adequate quantity of oil.

My 1912 Automobile

Some Conceptions of What the Ideal Car Should Be

A $5,000 Car

Editor The Automobile:

I would like to see an announcement along the following lines by some leading producer of high-grade cars: Motor, six-cylinder, Knight type; bore, 4 3-4; stroke, 6 inches; four speed selective transmission with direct drive on fourth.

Self-contained force feed and splash oiling systems.

I would specify a worm drive for the sake of silence and gas and spark control on top of steering wheel.

Double ignition should be installed and also a high-tension complete electric-lighting system, including dynamo.

Compressed air starting device, available for inflating tires, should be installed and also a carburetor air adjustment on steering column. The multiple disc clutch should run in oil.

The radiator and hood should be similar to Renault type, giving protection to radiator, better view of road, and (in my opinion) handsomer lines. I would specify an underslung frame for following reasons: 1st. A very large per cent of fatal accidents are caused by overturning. Any feature which lessens this danger seems to me important. 2d. Ease of entering car. 3d. Appearance.

The wheels should be of a size to give minimum road clearance of 11 inches. Steering column should have an extreme inclination (as in Lozier torpedo) for ease in steering, while the tires should be carried at rear, in an upright position.

Fore-door torpedo body, with comfortably high sides and backs and thick upholstery, is my choice, with overhanging cowl, carried well up and back toward steering wheel; seats 12 inches high from floor and a wheelbase of length to insure ample foot room for all occupants, especially in the front seats (say, 140 inches for six-passenger torpedo). Extra seats should be removable and a clamp for baggage should be on the running board. To insure beauty of outline the body lines should not exceed in height the top of the radiator and hood. Particular attention ought to be paid to all parts and adjustments, especially grease cups, the replenishing of which, on many cars, causes sinful language daily. A two-gallon reserve oil tank and a gas tank of 250 miles capacity, with drain cock for quick emptying of same, should be fitted. Rubber cushions between chassis and body to prevent squeaks should be a feature.

I would specify a full equipment, including speedometer, clock and windshield, with stay rods extending no farther in front than the dash. Top and demountable rims of course. The above figures are in no particular intended as exact. They merely express in a general way my ideal of a car and costing around $5,000. It is my impression that such a car would take with the class of buyers who want the best. C. O. M.

Putnam, Conn.

Likes a Heavy Car

Editor The Automobile:

No two people have the same ideas of cars, and each one believes in his own selections, but I am sure that a great many people will agree with most of my selections. I shall not give specifications of body design or length, width and number of spring leaves, etc., but will confine myself to the following:

The motor should be of the (T) head type, five-inch bore and six-inch stroke, four cylinders cast in pairs, with three-bearing crankshaft and valves two and three-fourth inches in diameter.

Four-speed transmission with three to one on fourth would give plenty of speed when desired and also produce a very quiet and easy running engine at moderate speed. The large engine would give plenty of power on the hills and with this transmission would prove more economical than a smaller engine. The gearset should be carried amidships, bolted to the frame.

The ignition should be double. I mean by double two separate systems even down to the switches. This allows both systems to be used at once.

The carbureter should be a multiple jet with auxiliary air intake to be regulated by hand from under the steering-wheel. This would give a very strong and flexible carbureter.

Lubrication should be by splash from oil troughs, oil reservoir being in bottom of crankcase. Oil should be pumped through a sight feed on dash; after being used it should be strained and sent through again.

Clutch would be of the expanding band type with cork inserts and a screw adjustment. This clutch would be extremely easy to remove and to adjust.

Drive should be through a shaft, direct drive being on fourth speed.

Steering should be by irreversible worm and sector gear. This design is adjustable and does not allow any of the road shocks to be transmitted to the driver's arms.

The springs should be of the platform type in the rear and semi-elliptic in front which ought to make an easy riding car.

Wheelbase should be 120 inches and tires all round 36 x 4 1-2.

Front axles should be I-beam with full floating axles in the rear. Full floating axles allow all weight to be carried upon the axle housing and wheels, while the axle has only the driving strain to take care of.

The body should have plenty of leg room in both seats; eleven inch clearance is required. Special attention should be given to the depth of seats and a space in car for extra tires.

Control should be above the steering wheel, moving upward. Acceleerator outside of clutch and brake pedals.

The two brakes should both work on the wheel drums, foot brake contracting, with emergency expanding.

This car could be built and marketed for $2,500 and should not weigh more than 3,400 pounds. Most people want light weight cars on account of the tire cost, but they must be careful not to rob the easy riding qualities of the car by making it light, besides the strength of each part necessarily comes before the question of weight.

W. J. Marlin.

Du Bois, Pa.

Wants the Car Well Made

Editor The Automobile:

There is an old saying that we want but little here below, but in my ideal car I might add that we want that little good. A motor with about 4-inch bore and 4 3-4-inch stroke capable of attaining 2,500 revolutions per minute. cone clutch, three speed selective transmission and worm drive would be the main characteristics. The magneto should be of the double-distributor type and the chassis should not weigh more than 1,600 pounds.

Price cutting in automobile manufacture must entail some cut either in material or workmanship and it is my firm belief that if a car were made of the best and the makers satisfied with a reasonable margin of profit there would be room for such a concern in the automobile business. The time will come when a car will sell on its merits rather than the fact that it is a few dollars cheaper than that made by some other competitor. M. P. H.

New York.

My Best Repair

A Chapter of Accidents

I WAS once confronted by what seemed to be a breakdown that would necessitate the car being towed into the nearest town or taking the gasoline tank off the car and taking it to some repair shop.

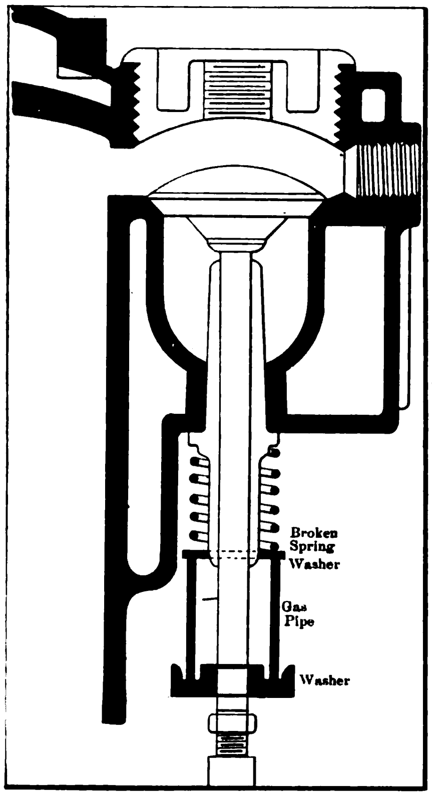

Fig. 1—Method of temporarily repairing a broken valve spring with a piece of gas pipe

Briefly what happened was as follows: I was driving a car over some very bumpy roads and the pipe inside the gasoline tank became unsoldered. The pipe carried the gasoline from the bottom of the tank under pressure so that when it broke it was impossible to feed the carbureter from the tank. The tank contained about 18 gallons of gasoline and at first I thought that there was a leak in the pressure circuit, but upon removing the cover of the float chamber I found that the pressure passed clean through the gasoline line. The filler of the tank was rather small; too small, in fact, to allow of putting the hand inside. Just at that moment a small boy was passing and with the aid of a few cents I prevailed upon him to put his hand inside and feel around to see if the pipe was broken or not. He was able to reach it, but as it lay at the bottom of the tank and there were baffle plates it was not possible to remove it.

The thought occurred to me to use a spare can of gasoline and syphon it out, but as I did not have a can on board I had to walk some distance to a house to procure one. Then came the question of syphoning the gasoline from the main tank to the improvised one and from the latter to the carbureter. The rubber connection of the tire pump served for the first operation all right, but was not long enough for the second. I took the copper pipe from the acetylene system and attached a piece of rubber tubing at each end, inserting one end in the emergency tank, which I placed in my companion's arms, as shown in Fig. 2.

A triangular file served as a hack-saw to cut the gasoline pipe about 10 inches from the carbureter. The only way to start the syphon working was to suck on it with my mouth and quickly connecting up the rubber tube to the feed pipe. The contraption lasted for about one hour, just sufficient to get me home, as the rubber was eaten away by the gasoline passing through it.

I learned, however, that using a flame on the gasoline tank was a very delicate operation even after leaving it for several hours with the filler and drain plugs removed. To make sure I pumped air with a tire pump through the tank for fully half an hour, but as soon as a flame was applied to remove the solder around the joint a terrific explosion took place and a fantail flame exuded from the filler, lapping the right side of my face. There happened to be a gear box that had been opened up, and I plunged my hand into it and smeared my face with the lubricant, which prevented the burn from taking much more effect than singeing my hair and causing the skin to peel.

New York. H. M.

Broken Valve Spring Repair

Being away on a tour and trusting to others to see that the car was in good shape before starting I had the misfortune to break a valve spring. Such a thing had never happened to me before, and I had neglected to carry a spare spring. I believe in always carrying a good piece of copper wire, a pair of pliers, adjustable wrench and hacksaw. With these three a repair can be made, as was proven in the present instance. The jack handle of my car was tubular, in fact, similar to a piece of gas pipe, so I cut off a sufficient length so as to insert it between the valve washer and a washer I happened to have on the car. By "happened" I mean I looked around the car till I came to one of the brake connections that had washers fitted and I removed it. The sketch shown in Fig. 1 illustrates the repair as executed.

Philadelphia. T. W. Wolf.

Burnt-Out Bearing—Got Home

I cannot remember ever having been called upon to exert any gray matter on the road in extricating myself from an embarrassing situation.

I remember once, however, that my engine began to pound in the front cylinder and upon removing the inspection cover I found that the bearing, which was of white metal, had started to run. Upon removing the connecting rod and piston from the cylinder I ran home on "three," averaging about 10 miles per hour.

Hartford. Burnt Out.

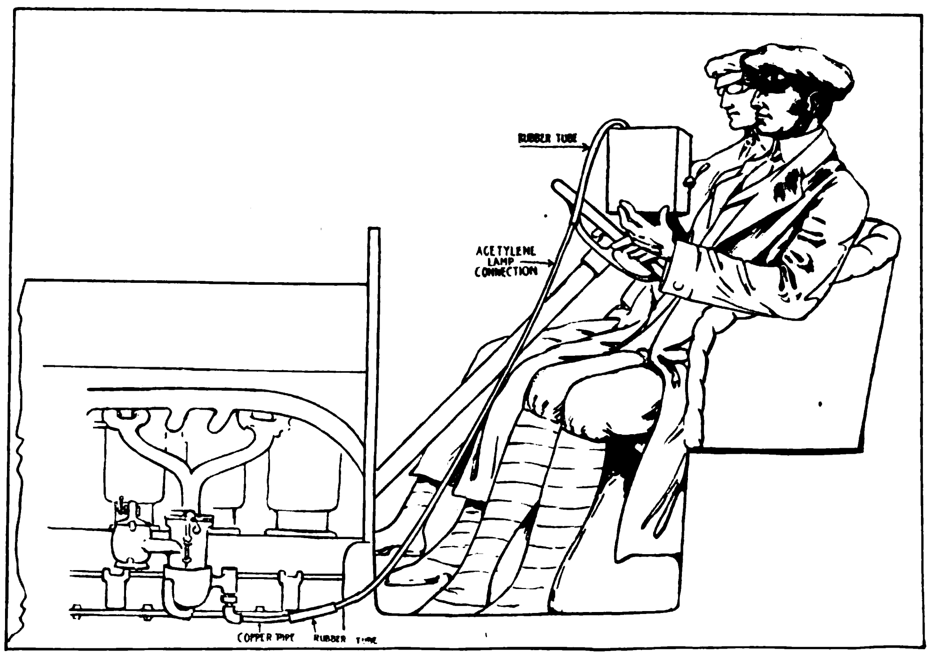

Fig. 2—Getting home with a defective gasoline tank by using the acetylene connections

M. & A. M. Allots Show Spaces

COMPLETE allotments of space for the shows in Madison Square Garden, New York; Coliseum and Armory, Chicago, and Mechanics' Hall, Boston, have been announced by the Motor and Accessory Manufacturers. The spaces for the exhibition in the New Grand Central Palace have not yet been assigned. Below is a list of the accessories exhibitors at the three shows mentioned:

Madison Square Garden for Both Weeks.

Ajax-Grieb Rubber Co., New York, N. Y.
American Ball-Bearing Co., Cleveland, Ohio.
American Circular Loom Co., Aldene, N. J.
Apple Electric Co., Dayton, Ohio.
The Badger Brass Mfg. Co., Kenosha, Wis.
The Baldwin Chain & Mfg. Co., Worcester, Mass.
Bosch Magneto Co., New York, N. Y.
S. F. Bowser & Co., Fort Wayne, Ind.
Briscoe Mfg. Co., Detroit, Mich.
Brown-Lipe Gear Co., Syracuse, N. Y.
Byrne, Kingston & Co., Kokomo, Ind.
Champion Ignition Co., Flint, Mich.
The Chandler Co., Springfield, Mass.
Chicago Telephone Supply Co., Elkhart, Ind.
Coes Wrench Co., Worcester, Mass.
Columbia Lubricants Co., New York, N. Y.
Columbia Nut & Bolt Co., Bridgeport, Conn.
The Connecticut Telephone & Electric Co., Meriden, Conn.
Consolidated Rubber Tire Co., New York, N. Y.
Continental Caoutchouc Co., New York, N. Y.
Covert Motor Vehicle Co., Lockport, N. Y.
The Wm. Cramp & Sons Ship & Engine Building Co., Philadelphia, Pa.
Crucible Steel Co., Pittsburgh, Pa.
The Dean Electric Co., Elyria, Ohio.
Diamond Chain & Mfg. Co., Indianapolis, Ind.
The Diamond Rubber Co., Akron, Ohio.
Jos. Dixon Crucible Co., Jersey City, N. J.
Dorian Remountable Rim Co., New York, N. Y.
Driggs-Seabury Ordnance Corp., Sharon, Pa.
Edison Storage Battery Co., West Orange, N. J.
The Edmunds & Jones Mfg. Co., Detroit, Mich.
Eiseman Magneto Co, New York, N. Y.
The Electric Storage Battery Co., Philadelphia, Pa.
Empire Tire Co., Trenton, N. J.
Firestone Tire & Rubber Co., Akron, Ohio.
The Fisk Rubber Co., Chicopee Falls, Mass.
G. & J. Tire Co., Indianapolis, Ind.
Gemmer Mfg. Co., Detroit, Mich.
The B. F. Goodrich Co., Akron, Ohio.
The Goodyear Tire & Rubber Co., Akron, Ohio.
Gray & Davis, Amesbury, Mass.
The R. E. Hardy Co.,
A. W. Harris Oil Co., Providence, R. I.
Hartford Rubber Works Co., Hartford, Conn.
Hartford Suspension Co., Jersey City, N. J.
Havoline Oil Co., New York, N. Y.
Herz & Co., New York, N. Y.
The Hess-Bright Mfg. Co., Philadelphia, Pa.
The Hoffecker Co., Boston, Mass.
Hyatt Roller Bearing Co., Newark, N. J.
Janney-Steinmetz & Co., Philadelphia, Pa.
Isaac G. Johnson & Co., New York, N. Y.
Phineas Jones & Co., Newark, N. J.
Jones Speedometer Co., New York, N. Y.
Atwater Kent Mfg. Works, Philadelphia, Pa.
Kokomo Electric Co., Kokomo, Ind.
Leather Tire Goods Co., Niagara Falls, N. Y.
Lebanon Steel Casting Co., Lebanon, Pa.
J. Ellwood Lee Co., Conshohocken, Pa.
Light Mfg. & Foundry Co., Pottstown, Pa.
Link-Belt Co., Indianapolis, Ind.
Lovell-McConnell Mfg. Co., Newark, N. J.
McCord Mfg. Co., Detroit, Mich.
The McCue Co., Buffalo, N. Y.
C. A. Mezger, New York, N. Y.
Michelin Tire Co., Milltown, N. J.
Morgan & Wright, Detroit, Mich.
A. R. Mosler & Co., New York, N. Y.
The Motz Clincher Tire & Rubber Co., Akron, Ohio.
Muncie Gear Works, Muncie, Ind.
National Carbon Co., Cleveland, Ohio.
National Tube Co., Pittsburgh, Pa.
The New Departure Mfg. Co., Bristol, Conn.
N. Y. & N. J. Lubricant Co., New York, N. Y.
The Noera Mfg. Co., Waterbury, Conn.
Oliver Mfg. Co., Chicago, Ill.
Pennsylvania Rubber Co., Jeannette, Pa.
Pittsfield Spark Coil Co., Dalton, Mass.
Remy Electric Co., Anderson, Ind.
The Republic Rubber Co., Youngstown, Ohio.
The Royal Equipment Co., Bridgeport, Conn.
A. O. Smith Co., Milwaukee, Wis.
The Sparks-Withington Co., Jackson, Mich.
Spicer Mfg. Co., Plainfield, N. J.
C. F. Splitdorf, New York, N. Y.
Standard Roller Bearing Co., Philadelphia, Pa.
The Standard Welding Co., Cleveland, Ohio.
Stewart & Clark Mfg. Co., Chicago, Ill.
Stromberg Motor Devices Co., Chicago, Ill.
Swinehart Tire & Rubber Co., Akron, Ohio.
The Timken-Detroit Axle Co., Detroit, Mich.
The Timker Roller Bearing Co., Canton, Ohio.
The Turner Brass Works, Sycamore, Ill.
U. S. Light & Heating Co., New York, N. Y.
Vacuum Oil Co., New York, N. Y.
Vanadium Metals Co., Pittsburgh, Pa.
The Veeder Mfg. Co., Hartford, Conn.
Warner Gear Co., Muncie, Ind.
Warner Mfg. Co., Toledo, Ohio.
Weed Chain Tire Grip Co., New York, N. Y.
Weston-Mott Co., Flint, Mich.
Wheeler & Schebler, Indianapolis, Ind.
Whitney Mfg. Co., Hartford, Conn.
J. H. Williams Co., Brooklyn, N. Y.
O. W. Young, Newark, N. J.
Federal Rubber Mfg. Co., Cudahy, Wis.
Detroit Electric Appliance Co., Detroit, Mich.
Carnegie Steel Co., Pittsburgh, Pa.
Automobile Supply Mfg. Co., Brooklyn, N. Y.
The Simms Magneto Co., New York, N. Y.
International Acheson Graphite Co., Niagara Falls, N. Y.
The Buda Co., Harvey, Ill.
Stutz Auto Parts Co., Indianapolis, Ind.
Bower Roller Bearing Co., Detroit, Mich.
United Rim Co., Akron, Ohio.
Jacobson-Brandow Co., Pittsfield, Mass.
General Electric Co., Schenectady, N. Y.

Madison Square Garden for First Week Only

Gustave Gobron, head of the Société Gobron-Brillie, and for many years a leader in automobile circles in France, is dead. He was born in 1846 and received high honors during his life. He was chevalier of the Legion of Honor.

Albany, N. Y., Oct. 9—William H. Catlin, state superintendent of roads, died recently. Col. Catlin had been at the head of the New York road department only a short time, but during his brief administration made many improvements.

Big Entry List for Santa Monica

LOS ANGELES, Oct. 6—Forty cars are promised to start in the four events to be run in the third annual road races at Santa Monica on Saturday, October 14. This is the largest entry list ever gotten together for any western road race. The course has been put in excellent shape and the drivers expect to see a new record set for the course, which has proven to be the fastest in America.

Three of the four events will be classified by piston displacement only, all of the events will be non-stock.

In the free-for-all, which will be twenty-four laps of the 8.417 mile course, some of the fastest cars in America will be contenders.

Heading the entry list is a Fiat 90, driven by Teddy Tetzlaff, who set a new American record on the course last year with a Lozier averaging 73.27 miles per hour. Harris Hanshue, who won the first Santa Monica race with an Apperson, will pilot a Mercer.

Bert Dingley has purchased and entered the Pope-Hartford that he drove into first place this year in the Oakland-Portola road race.

Harvey Herrick will pilot a National. Herrick won the Los Angeles to Phoenix road race of nearly 500 miles last year with a Kissel.

Another of the local Western drivers that will be well placed in this race is Joe Nickrent, who has joined forces with the Marmon team.

These Western boys will have to compete with Wilcox and his National, Joe Dawson, Bill Endicott and Cyrus Patschke of the Marmon team, Disbrow and his Ohio, T. S. Duby and the Midland six, Dave Lewis on the Stutz and Harry Endicott, with the Inter-state.

The National team will have Merz and Aiken in reserve to be used if necessary. Ray Harroun will be here as manager of the Marmon team and may decide to take the wheel of one of the cars himself. The heavy car class with its minimum limit of 301 inches and the medium class running from 231 to 300 will be run simultaneously. The distance will be 151 miles or eighteen laps of the course.

There are four entries so far in the heavy car class most of the drivers preferring to hold out for the free-for-all with its larger purse and finer trophy.

In the 300 and under class will be entered two Coles with Johnny Jenkins and Frank Siefert driving. Hanshue will pilot the Mercer, Joe Nickrent and Bill Endicott will have Marmons, Louis Nickrent will handle the Buick, C. E. Bigelow will pilot the Lexington, McKeague who drove the Durocar into first place in this class last year will try to repeat his winning. A Schacht and a Parry are promised but no drivers nominated as yet.

In the mosquito fleet, limited to 230 inches, the line-up will consist of the Maxwell that won last year, with Clarence Smith driving. Smith purchased the car and is entering it himself. Frank Charle will drive a Ford, Frank Siefert a Paige-Detroit, Louis Nickrent a Buick, and Anthony a Regal. Hanshue will be in this event also at the wheel of a Reo. This will give Hanshue 450 miles to go to finish in all of the three events in which he has entered. A Flanders and an E-M-F promised will complete the list for the midgets.

Bert Dingley, Frank Siefert, Joe Nickrent and Harvey Herrick are each entered in two out of the three races.

The course will be open for early morning practice to-morrow. The National team is here and has established a camp at Santa Monica, and will be out early to get the cars tuned up.

A number of the cars are ready for the final road tests and the coming week will see the residents along the course among the list of early risers whether it will be from choice or not.

Four big silver trophies are offered. The perpetual challenge cup given by Dick Ferris will go to the winner of the free-for-all. Leon T. Shettler's trophy will go to the winner in the heavy car class while two new trophies offered by Chanslor & Lyon and J. A. Jepson will go to the winners in the medium and light car class respectively.

In addition to the trophies over $10,000 in cash will be divided among the cars that run in the money. Part of the cash prizes are offered by tire and ignition firms and only cars carrying their equipment are eligible for that part of the purse. Races run over the Santa Monica course in former years have been productive of notable contests. The course is acknowledged to be one of the fastest and safest in the United States.

Colby Star Performer at Omaha

OMAHA, NEB., Oct. 9—The rain has proved the most consistent winner in the automobile races at the Omaha Speedway. The races were originally scheduled for September 30 and October 1, 2 and 4. They had to be postponed twice, but finally the first day's events were pulled off Wednesday, October 4. The second day's races were to have been held Friday, but again the rain interfered.

Pierce in a Colby carried off every contest he was allowed to enter on Wednesday in some of the fastest racing ever witnessed on this track.

In the 10-mile race for cars under 231 cubic inches displacement the Firestone-Columbus and Abbott-Detroit fought for first place throughout, the former winning by a quarter of a second.

In the first race the Colby was followed closely by the Firestone-Columbus and the Abbott-Detroit, but won the last easily. In a speed trial the Colby did 5 miles in 4:48. Following are the summaries:

10 Miles. 301 Cubic Inches Displacement or under

Position.	Car.	Driver.	Time.
1.	Colby	William Pierce	10:09
2.	Firestone-Columbus	Ed. Richenbacher	.....
3.	Chalmers	William Bruner	.....

10 Miles. Under 231 Cubic Inches Displacement

Position.	Car.	Driver.	Time.
1.	Firestone-Columbus	Richenbacher	11:47⅘
2.	Abbott-Detroit	Smith	11:48
3.	Chalmers	Bruner	.....
4.	Page-Detroit		withdrawn

25 Mile Free-for-All for Speedway Cup

Position.	Car.	Driver.	Time.
1.	Colby	Pierce	24:52¼
2.	Firestone-Columbus	Rickenbacher	.....
3.	Abbott-Detroit	Smith	.....
4.	Paige-Detroit		withdrawn in fifth lap

Second Day

OMAHA, Oct. 10—The races in Omaha had to be postponed again until Sunday. Pierce in his Colby 40 again carried off the honor, winning the Speedway cup. Summary:

50-Mile Free-for-All

Position.	Car.	Driver.	Time.
1	Colby	Pierce	48:45½
2	Cutting	Ernest Delaney	70:23
3	Firestone-Columbus withdrew,	end of 45th mile.	
4	Mercer	Baker	Withdrew

5-Mile Speed Trials

Position.	Car.	Driver.	Time.
1	Colby	Pierce	4:44
2	Cutting	Delaney	5:21½
3	Firestone-Columbus	Rickenbacher	5:24½

Obstacle Race, 10 Miles

Position.	Car.	Driver.	Time.
1	Mercer	Baker	19:09¾
2	Chalmers	Bruner	

Truck Wheel Standards Extended

AT the meeting of the Division on Wheel Dimensions and Fastenings for Tires of the Standards Committee of the Society of Automobile Engineers held at the office of the society, 1451 Broadway, New York City, on Oct. 5 the following were in attendance: S. A. E. committee, W. P. Kennedy, chairma C. L. Schwarz, E. R. Whitney, C. B. Whittelsey, J A. Anglada and Coker F. Clarkson, secretary. Those representing the tire companies included H. W. Dupuy, Polack Tyre Company; A. Hauschild, Polack Tyre Company; E. R. Hall, Goodyear Tire & Rubber Company; W. H. Allen, The B. F. Goodrich Company; P. A. Aspell, The B. F. Goodrich Company; John C. Cole, Fisk Rubber Company; B. C. Swinehart, Republic Rubber Company; W. W. Wuchter, Swinehart Tire & Rubber Company; C. A. Swinehart, Swinehart Tire & Rubber Company; A. A. Brewster, Diamond Rubber Company; F. F. Phillips, U. S. Tire Company; J. L. Gibney, James L. Gibney & Bro.; J. W. Thomas, Firestone Tire & Rubber Company; S. G. Carschuff, Firestone Tire & Rubber Company; B. C. Swander, Firestone Tire & Rubber Company; E. Roberts, Kelly-Springfield.

The first subject taken up was the matter of a standard bolt hole circle for the flange type of solid motor tire. It was the sense of the meeting that the S. A. E. committee be requested to recommend the adoption of 1-2 inch as the diameter of through bolts for all sizes of solid motor tires.

Also that the diameter of the bolt hole circle for 36-inch tires should be 28 1-2 inches, and increase or decrease by even 2 inches for tires larger or smaller than 36 inches.

As to the number of bolts to be used, it was the sense of the meeting that for tires up to and including 36 inches diameter there should be 8, 12 or 24 bolts equally spaced where required; for tires above 36 inches and up to and including 42 inches there should be 10, 15 or 30 bolts equally spaced where required; for tires above 42 inches and up to and including 48 inches there should be 12, 18 or 36 bolts equally spaced where required and for tires above 48 inches and up to and including 54 inches there should be 14, 21 or 42 bolts equally spaced where required.

It was voted that the manufacturers of commercial motor vehicles should be requested to inspect wheels which they purchase according to S. A. E. standards and to mark the same with a symbol visible at all times in the life of the wheels.

William E. Metzger, president of the National Association of Automobile Manufacturers, expressed the gratification of the manufacturers as to the S. A. E. standardization work and the belief that they would fully support the particular standardization under consideration at this meeting, namely the truck wheel having a constant diameter for all widths of solid motor tires of a given diameter, and a permanent metal band of 1-4 inch thickness for some sizes and 3-8 inch for others, the idea being that this metal band should never be removed from the wheel under any circumstances, but remain as the common basic point from which all the makers of solid tires are to work, all special steel equipment necessary to the application of the respective makes of solid tires being attached to the outside of this permanent metal band.

The society has just announced the details of the S. A. E. screw standard which supplants the A. L. A. M. screw standard, which was adopted by the Association of Licensed Automobile Manufacturers in April, 1906. The standardizing of nuts and bolts was a work of such magnitude and far-reaching usefulness that it may well constitute an enduring monument. It was work akin to bringing order out of chaos. The standard was an almost immediate mechanical success, the good results being felt not more by manufacturers than by dealers and drivers.

The only changes which have been made by the S. A. E. in the old standard are as to the distance across flats of the heads and nuts of the 1-4, 7-16 and 3-4-inch screws, the changes being from 3-8 to 7-16, from 11-16 to 5-8 and from 1 1-8 to 1 1-16 inch respectively. The A. L. A. M. screw standard did not go beyond 1-inch diameter screw. The S. A. E. standard proceeds by 1-8 and including 1 1-2-inch diameter screw.

Calendar of Coming Events

Shows

Oct. 7-14..........Chicago, Ill., Show of Chicago Automobile Trade Association.
Jan. 6-13..........New York City, Madison Square Garden, Twelfth Annual Show, Pleasure Car Division, Automobile Board of Trade.
Jan. 6-20..........New York City, Madison Square Garden, Annual Show, Motor and Accessory Manufacturers.
Jan. 10-17........New York City, Grand Central Palace, Twelfth Annual Show, National Association of Automobile Manufacturers; also Motor and Accessory Manufacturers.
Jan. 15-20.........New York City, Madison Square Garden, Twelfth Annual Show, Commercial Division, Automobile Board of Trade.
Jan. 27-Feb. 10....Chicago Coliseum, Eleventh Annual Automobile Show under the auspices of the National Association of Automobile Manufacturers. Pleasure cars, first week. Commercial vehicles, second week.
Feb. 14-17.........Grand Rapids, Mich., Third Annual Show.
Feb. 19-24.........Hartford, Conn., Annual Show, Automobile Club of Hartford, State Armory.
Week Feb. 22.....Cincinnati, O., Annual Show, Cincinnati Automobile Dealers' Association.
March 2-9.........Boston, Mass., Tenth Annual Show, Boston Automobile Dealers' Association, Inc.

Meetings, Etc.

Nov. 20-24........Richmond, Va., First American Road Congress, under auspices of American Association for Highway Improvement.
Nov. 23........ . Road Users' Day, under direction of Touring Club of America.
Jan. 18-20.........New York City, Annual Meeting of the Society of Automobile Engineers.

Race Meets, Runs, Hill-Climbs, Etc.

Oct. 9-13..........Denver, Colo., Reliability Run, Denver Motor Club.
Oct. 11-18.........San Francisco, Cal., Reliability Run, Good Roads Assn. of Northern California.
Oct. 13-14..........Peoria, Ill., Track Races, Peoria National Implement and Vehicle Show.
Oct. 14............Santa Monica, Cal., Road Races.
Oct. 14 (to 26)....New York City, Start of the Annual Glidden Tour, en route for Jacksonville, Fla.
Oct. 30...........Minneapolis, Minn., Hill Climb.
Oct. 20-21.........Sioux City, Iowa, Track Races, Sioux City Automobile Club.
Oct. 21........... Atlanta, Ga., Track Races.
Oct. 21............ White Plains, N. Y., Track Races, Westchester Driving Club.
Oct. 27-Nov. 3.....Chicago, Ill., Thousand-Mile Reliability Run, Chicago Motor Club.
Oct. 28...........Newark, N. J., Reliability Run, Newark Motor Club.
Oct. 30............Harrisburg, Pa., Economy Run, Motor Club of Harrisburg.
Oct. 31............Shreveport, La., Track Races, Shreveport Automobile Club.
Nov. 2-4...........Philadelphia, Reliability Run, Quaker City Motor Club.
Nov. 3-4...........Columbia, S. C., Track Races, Automobile Club of Columbia.
Nov. 4-6...........Los Angeles-Phoenix Road Race, Maricopa Auto Club.
Nov. 9.............Phoenix, Ariz., Track Races, Maricopa Automobile Club
Nov. 9, 10, 12.....San Antonio, Tex., Track Races, San Antonio Auto Club.
Nov. 27...........Savannah, Ga., Vanderbilt Cup Race, Savannah Automobile Club.
Nov. 30...........Los Angeles, Cal., Track Races, Motordrome.
Nov. 30...........Savannah, Ga., Grand Prize Race, Savannah Automobile Club.

THE AUTOMOBILE

Vol. XXV Thursday, October 12, 1911 No. 15

THE CLASS JOURNAL COMPANY
H. M. SWETLAND, President
CONDE NAST, Vice-President and General Manager
E. M. COREY, Secretary and Treasurer

Entered at New York, N. Y., as second-class matter.
The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

Comfort Is Essential

AUTOMOBILE buyers are looking for comfort in the cars they are going to purchase for the coming year. Two or more years ago the buyer did not give comfort much thought; he was glad to get a car in those halcyon days and it was of more concern to him to get a car with a good motor, a good gearset and a good running gear than one with special body comforts. To-day the situation is different. The majority of the buyers acknowledge that there are over two-score cars in which the motors are so well made that they will give all that is demanded in the matter of satisfaction; there are to-day two-score or more cars in which the gearsets and axles meet the expectations of the most fastidious; but there are not so many cars to-day that give everything that is asked for in the way of easy riding. Easy riding and comfortable seats with comfortable foot room are factors that will sell cars for 1912. Take two cars of equal reputation for stability in the motor, clutch, gearset and axles, that car with the better body suspension, with the better upholstery and with the more foot-and-leg comforts will prove the better seller. Some makers have grasped this idea already; they are up to date: others will grasp it when they have allowed the rival to get the benefit of the early bird.

It is natural that good spring suspension should be a factor in determining which automobile is to be purchased. It is natural that the woman who has to ride in the tonneau should instruct her husband to purchase the car that is the more comfortable to ride in. Not a few sales of 1912 cars have been clinched by the verdict of the tonneau should instruct her husband to purchase the motor of one may be better than that of another: the magneto on one may have some advantages over that of the other; but to the rear-seat passenger the comfort factor is one that cannot be overlooked. It is a prime consideration in the matter of selling cars; it is so important in these days when real salesmanship is needed that those concerns whose cars have stiff springs and uncomfortable seats will discover that it is time to use good springs, good upholstery and other body comforts.

The automobile manufacturer must wrestle with the matter of passenger comfort. Some are doing it to-day, but they have not succeeded as well as others. Naturally the first offered solution is that of fitting shock absorbers. This is a good solution providing the shock absorber is suited to the car load, and further provided that the absorber is kept in proper adjustment. But a shock absorber adjusted to a three-passenger load in a big touring car will not act well if seven or eight adults are in the machine; on the other hand, when the shock absorber is adjusted to a load of seven people the car suspension will not be the best when there is one lone person in the back seat. A simple solution would be the fitting of a device to the shock absorber that would allow of very quickly changing the adjustment to suit the different loads; but what driver would think of making the adjustment? Such an adjustment should be made before going on long cross-country trips.

The final solution of the problem is an engineering one. It is not always the shock absorber and it is not always the set of springs; the general design of the car plays its part. Every car owner has ridden in automobiles that will hold the road perfectly at fairly high speeds, whereas others at the same speed will be jumping all over the road. The reason is at hand: One is a well-balanced car, the other one is poorly balanced. The well-balanced car, if it holds the road perfectly, must of necessity ride more easily. It may not have much better springs than the poorly-balanced car, it may not have any better shock absorbers, but still it is a more comfortable car; it is a better-balanced car.

The matter of balance is attracting the attention of engineers to-day, but they do not know enough about the other engineer's car to pick out the bad points in their own. There is a solution, at least there is a way of bringing to the attention of the engineers that matter of suspension, and that is a contest in which suspension will be featured. In the early days of the automobile, when the cars were not properly braked, it was the reliability runs over the mountainous roads that impressed on the makers the necessity of more and better braking surface; when fenders were not strong enough to withstand continuous rough road usage it was the technical examination at the end of the endurance run that impressed it on the engineer; and to-day there is not any reason why a test on suspension would not serve to inform the engineer of the exact status of the suspension of his car. Such a test would not be a difficult one. It would require the attachment of some form of pointer, or needle, to the car axle and another needle to the car frame. Both should trace their up-and-down movement, or vibration, on a chart. All of the contesting cars would be fitted with the same device, which could be so designed as to be readily attached to any car. With a device of this nature in place, all of the contesting cars, with required load, would have to drive at different speeds over a certain surface, which might contain such road irregularities as street car crossings, cross ridge, cross rut and other holes. The tracings of the pointers on the chart would tell the story. There would not be any chance for deception in such a contest. The expertness of the driver would be a factor as it is in any form of contest, but in spite of this the test would be a really practical one. It would be an eye-opener to a good few makers. It would be a car seller to the concerns that had a good suspension.

There are some body comforts which are factors in making car sales, which call for immediate attention. It is a certainty that some of the engineers would never have made the clutch and service brake pedals so high if they had driven the car for an entire day. In others the sloping part of the floor boards in front is too short to accommodate the foot without the toe of the shoe rubbing against the highly-finished mahogany dash. The dash is soon disfigured. A little common sense would have remedied this before the car left the designing department. On some cars it is impossible for one person to ride with any degree of comfort in the tonneau seat. Instead of there being a comfortable rearward slope to the upholstery, there is a forward slope tending to throw the passenger ahead. At other times the foot rail is either too far away or too near, and without any means of adjustment. The lack of body comforts could be enlarged upon, but it is not necessary. It is becoming more and more a necessity and the time is at hand when body comforts will be perhaps more of a selling factor than the particular make of carbureter, magneto or axle used. It is a field to which makers should give attention.

Twenty Three-Car Teams in Glidden

SHARPLY at 9 o'clock Saturday morning, the touring column of the 1911 Glidden Tour will start from Fifth avenue and Thirty-ninth street on its journey to Jacksonville, Fla. The procession will be headed by a platoon of mounted police, behind which will be ranged 82 automobiles. Of this number 72 will be contestants for the Glidden Trophy or for the individual trophy offered by the city of Anderson, S. C.

Arrangements have been made with the State of New Jersey for touring privileges. For a time this phase of the tour looked dark as the officials of the State said that they wanted a full yearly touring license from each entrant and official car for the privilege of passing through the sacred precincts. This rule was later modified for the sake of general results and the tourists will not be required to take out licenses for a year.

The course will be across the Cortland street ferry, where the cars will be officially checked out. From there the route carries the party through Jersey City and Newark, reaching Philadelphia late in the afternoon.

Any State license carried by automobiles in the column will be good everywhere else that the route touches. In Virginia the cars will have to bow to the mediæval toll-gate regulations and it is understood that the rates have been raised down through the Old Dominion on the broad general ground that times are hard.

There will be approximately twenty three-car teams contesting for the Glidden Trophy. The other dozen cars will go along for the individual prize.

The teams so far as they have been formed are as follows:

Atlanta Team 1: Flanders 8, C. S. Winn; Flanders 61, E-M-F Atlanta Company; Flanders 63, Decatur, Ga. Board of Trade.

Tarrytown team: Maxwells 1, 2 and 3, U. S. Motor Company.

Nashville team: Marathons 56, 57 and 58, entered by J. M. Downing, Dr. R. L. Dozier and Dr. Vernon Hutton.

Atlanta Journal team: Inman Gray, American 5; James R. Gray, Thomas 6; Maj. J. S. Cohen, White 7.

Waltham team: Metz 15, 16 and 17, Metz Company.

Albany, Ga., team: Halladays 34, 35 and 36, entered by D. P. DeBerry, C. E. Fryer and Streator Motor Car Company.

Atlanta team 2: C. H. Johnson, Stevens-Duryea, 11; Crawford Wheatley, Stevens-Duryea, 39; Brooks Morgan, Stevens-Duryea 66.

Detroit team: Flanders 53, 54 and 55, entered by the Studebaker Corporation.

Atlanta team 3: St. E. Massengale, Garford 18; L. C. Brown, Mitchel 19; Griffith Implement Company, Schacht 20.

Atlanta team 4: Fords 43, 44 and 45, entered by Carolina Portland Cement Company, E. M. Willingham and I. O. Teasley.

Atlanta team 5: E. P. Ansley, Pierce-Arrow, 10; B. M. Grant, Marmon, 12; E. Rivers, Pierce-Arrow, 64.

Atlanta team 6: Hoke Smith, Maxwell 4; William D. Alexander, White, 14; J. Epps Brown, Thomas 22.

Athens-Commerce team: C. J. Hood, Columbia, 24; Athens Motor Car Company, Columbia 49; Bishop and Varner, Maxwell, 50.

South Georgia team: W. E. Aycock, Moultrie, Knox, 25; Henry Tift, Tifton, Rambler, 38; Martin and Reese, Hahira, Cadillac, 59.

Ad Men's Club team: Atlanta Club, Corbin, 21; Anderson, S. C. Club, Mitchell; Greensboro Chamber of Commerce, Case, 71.

In addition to the foregoing there will be fifteen Florida cars, mostly Cadillacs which will be formed into five more teams. Some of the remaining individual entrants may team up with friends and acquaintances just before the column of automobiles is sent away.

New A. B. of T. Committees Named

The new committees for the year were announced at the quarterly meeting of the members of the Automobile Board of Trade, held last week at the New York headquarters, 7 East Forty-second street. The new committees are as follows:

Patents—C. C. Hanch, W. H. Van Dervoort, L. H. Kittredge, A. Macauley.

Legislation and Law—G. H. Stilwell, Wm. B. Hoyt, Albert L. Pope.

Trade—H. O. Smith, E. R. Benson, W. E. Metzger, C. W. Churchill, W. T. White.

Intercourse and Arbitration—G. E. Daniels, W. C. Shepherd, J. W. Gilson.

Good Roads—R. D. Chapin, S. D. Waldon, J. N. Willys.

Statistical—Benj. Briscoe, E. P. Chalfant, J. S. Clarke.

Publicity—Alfred Reeves, E. R. Estep, H. W. Ford.

Show—George Pope, Alfred Reeves, M. L. Downs.

Mechanical Co-operation—A. L. Riker, D. Ferguson, F. B. Stearns, C. W. Nash, H. E. Coffin.

Road Enthusiasts Will Tour to Richmond

Several road tours with Richmond, Va., as the objective point are being organized by good roads associations in various sections. The tours that are forming will be composed of those working for and interested in the good roads movement who purpose to attend the forthcoming convention of the American Road Congress at Richmond, November 20-24, under the auspices of the American Association for Highway Improvement.

The Touring Club of America reports that among the tours being projected are the following: From Quebec, under the direction of Howard D. Hadley, covering Canada, New England and New York; from Atlanta, under the leadership of Leonard Tufts, taking in a large part of the South and another tour from the Southwest, particularly reaching Tennessee.

Electrics at the Palace

THE new Grand Central Palace opened its doors Wednesday to the Electric Exhibition. The main floor contained appliances for electrical cars, both pleasure and commercial, as well as for motors and other electrical devices. An opening lunch was given by the Edison Electric Company to the different exhibitors on the first floor, which afterwards is to be used as a demonstration ground for interested spectators to take trials of the vehicles. A model garage is being erected on this floor to show the latest improvements in the matter of fittings.

A goodly number of manufacturers of electrically propelled vehicles have taken space and are exhibiting different models of their manufacture. They have taken the situation in hand wholeheartedly and feel confident that in the field to which they particularly cater, viz., the town and suburban service, they are holding their own. The question of batteries, according to one prominent manufacturer, is no longer the bugbear to be overcome. These have been greatly perfected in the last few years so that it is now possible to cover a large area without recharging. With this and the improvements made in construction in general the mileage radius has been materially increased. Pneumatic tires are extensively used on pleasure cars, but the cushion type tire is favored by some, as it relieves the driver of all anxiety on this score, at the same time rendering the vehicle simple to handle—a great feature in cars intended for ladies' use.

The general characteristic features of the chassis and suspension of the gasoline car shows signs of being more closely followed and in the case of a few makers runabouts have been built resembling the gasoline runabout, with wheel steering and control on the wheel. Among these may be mentioned the Detroit electric and the Bailey. The makers of the latter have on exhibition a runabout that is capable of attaining a speed of 30 miles per hour and the identical car shown ran from Boston to New York in 12 hours' running time, averaging 20 miles per hour.

Shaft drive for the pleasure electric seems to be making converts and one maker who caters to both trades stated that he was selling many more shaft-driven electrics than the chain-driven variety. Practically every car on exhibition in the main hall was fitted with independent brakes operating on drums attached to the driving wheels, controlled by a pedal independent of the motor brake, which is operated by the control lever. Various types of control are shown and this part of the cars' mechanism seems to have been simplified.

A note struck by one manufacturer seems to be a possible solution of one of the difficulties at present in the minds of prospective buyers of commercial vehicles. Salesmen in their endeavor to make sales are not confining themselves to facts, and instead of coming out in the open and stating that the electric vehicle is primarily a town and short delivery vehicle are endeavoring to overestimate its value. Most of the makers are turning out at least one and in some cases two new models for the coming season. The general feeling is that when people become more educated to the possibilities of the electric that many more sales will result.

The Edison Company is placing two new batteries on the market similar in construction to the present type, but with larger capacity. They will be known as the A-10 and A-12 types, for 3 1-2 and 5-ton work respectively. The unit is comprised of 60 cells and the A-10 type has a 275 ampere-hour capacity, while the A-12 type has a capacity of 450 ampere-hour. The weight of each cell respectively is 32 and 29 pounds.

Detroit in Week's News

DETROIT, MICH., Oct. 9—As a result of a movement now under way in the Detroit Board of Commerce, shipments of Detroit-made automobiles to South America and other foreign markets are likely to be very materially increased in the future. The first steps toward the organization of an export bureau, as an adjunct of the board, were taken last week, when President Milton A. McRae pointed out the possibilities that await local manufacturers in many of the foreign markets, especially in South America.

The Elmore Automobile Company, 754 Woodward avenue, has taken the agency for the Reo.

In addition to the extensive improvements that are being made at its Detroit plants, the Studebaker Corporation is planning to add 40,000 square feet of floor space to its Windsor plant. The Dominion Stamping plant, which is a branch of a Detroit company, will also be enlarged.

The Harger Steam Truck Company, of New York, has been organized by several prominent Detroiters, headed by John S. Harger.

Rotary valve construction was the subject of an interesting discussion at the meeting of the Detroit chapter of the Society of Automobile Engineers, Friday evening.

Bristol Scouts Reach Washington

RICHMOND, VA., Oct. 9—The highway scouts promoting the connecting link in the National Highway between Bristol, Tenn., Va., and Washington, D. C., met with rousing receptions at every stopping point and reached Washington to-day.

The scouting party left Bristol with five cars in line.

After attending the third annual meeting of the Appalachian Good Roads Association the scouts started on a tour of the Shenandoah Valley, on the way to Washington.

Flanders Stars at Bedford Climb

INDIANAPOLIS, IND., Oct. 11—About 4,000 persons attended the hill climb held on Bright's Hill, Bedford, an 8 per cent. grade. There were no serious accidents. Spectators were present from a radius of 100 miles and the climb was arranged by motor car interests of Bedford. A summary of events follows:

Pos.	Car.	Driver	Time
	Cars of 230 Cubic Inches and Under		
1	Flanders "20"	Clayton Pierce	:53 3/5
2	Flanders "20"	Frank B. Willis	
3	Buick	D. H. McCoy	
	Cars of 231 to 350 Cubic Inches		
1	Marion	Ira Matthews	:47 3/5
2	Westcott	John D. Glover	
	Free-for-All		
1	Flanders "20"	Clayton Pierce	:42
2	National "40"	Ross McCoy	
3	Pope-Hartford	Frank Fox	

Bad Weather Kills Danbury Meet

DANBURY, CONN., Oct. 7—The automobile races which were to be held in connection with the county fair here were called off by Secretary Schumaker, of the Contest Board of the A. A. A., owing to the slippery condition of the track following the rain.

The track is a half-mile dirt course of elliptic shape. The stretches are comparatively long, making sharp turns at either end of the ellipse. It was on this track that De Palma went through the fence two years ago and sustained a broken leg. Two other drivers went through the fence at the same spot last year. The track was in good condition when these accidents happened.

Place and Show Money in Savannah Races

SAVANNAH, GA., Oct. 9—Additional purses for the placed cars in the Vanderbilt Cup, Tiedeman Trophy and Savannah Challenge Cup races have been hung up by the Savannah Automobile Club. In the Vanderbilt, a second prize of $500 and a third prize of $250 have been offered, while in each of the other races second money amounting to $250 and third money of $125 will be paid.

Springfield Sees Races

SPRINGFIELD, ILL., Oct. 9—The automobile races on Saturday, the closing date of the Illinois State Fair, served to draw out the largest crowd of the week.

The large crowd was only partially pleased with the meet, the close finishes which were staged and the lapping of cars at the grand stand being the only redeeming features of the exhibition.

There were only three real races in the entire card, the pursuit, the special race for the club championship and the 5-mile battle between the two Staver-Chicagos and the Case. All the others were flukes and failed to excite applause or appreciation.

McNay drove a great race in the Illinois Club championship, winning the $600 trophy for the Springfield automobile club from Monckmeier in his Staver-Chicago, representing the Chicago Motor Club, after Wonderlick, representing Bloomington in a Buick, had dropped out in the second mile.

Heineman, driving a Case, defeated Monckmeier in the 5-mile race with Knudson, also in a Staver-Chicago, third. The summary:

Match Race, 2 Miles; Automobile Versus Aeroplane

Car.	Driver	Position	Time
Marmon	Harroun	1	2:49¼
Wright-Biplane	Turpin	2	

Stock Cars, 2 Miles

Staver-Chicago	Monckmeier	1	2:22
Staver-Chicago	Knudson	2	

Time of tire change, 54½ seconds.

Exhibition, 3 Miles with Tire Change

Marmon	Harroun		3:28

Handicap, 3 Miles

Marmon	Harroun	1	3:25
Case	Heineman	2	

Class C, 300 Inches and Uunder, 5 Miles

Case	Heineman	1	5:38¼
Staver-Chicago	Monckmeier	2	
Staver-Chicago	Knudson	3	

Free-for-All, 3 Miles

Mercedes	Burman	1	2:52¼
Hotchkiss	Kilpatrick	2	
Benz	McNay	3	

Illinois Club Championship

Staver-Chicago	McNay	1	10:21½
Benz	Monckmeier	2	

Free-for-All Handicap, 5 Miles

Staver-Chicago	Monckmeier	1	4:29
Staver-Chicago	Knudson	2	
Hotchkiss	Kilpatrick	3	

Bergdoll Won Fairmount

(Continued from page 611.)

cian must be carrier over the full route except in case of illness. As the claim has not been advanced that Willoughby was taken suddenly ill, the referee had nothing else to do but to disqualify the car.

The appearance of the stands was somewhat different from last year. According to the new rules, the pits must be stationed at least 15 feet away from the nearest portion of the stands. As the Fairmount Park course is quite narrow at the place used for the official stands, it was found necessary to remove the pits to the west side of the main seats and entirely away from the view of the press and official quarters.

Thus, when a car signalled the pits from the upper end of the home stretch, it was with much difficulty that the newspapermen and officials could determine its identity until it started away again. There was very little mechanical difficulty experienced by the cars. The Fiat and Mercer No. 5 were the only ones to succumb to such. It was found functional trouble that put out the Cole, while the sole accident of the day fell to the lot of the Case. It was plain slowness and tire trouble that ailed the other losers. Only about half of the tire repairs were made at the pits, thus the impression was received that there was an abnormal lack of tire trouble for the Fairmount Park course. This was not true, because the cars averaged about four changes during the running, but the changes were largely made out of range of the official stands.

Chairman Edwards was exceedingly active. Prior to the race he examined the cars, measuring the cylinders to establish their classes. He acted as assistant starter and during the race itself he maintained a kind of running inspection of the cars to insure against accidents that might happen as the result of neglected wear and damage.

At the finishing line he nodded to the starter to wave the various flags. Not once did he order the white flag used, signifying danger, but on two occasions he authorized the yellow signal which meant that the drivers must continue with caution.

One of these occasions was in the early part of the race when a car in making tire changes on the back stretch, failed to clear the whole width of the course. The yellow flags waved for two rounds, which probably caused several of the cars to lose ground as a result of obedience to orders. It was frequently remarked at the time that the warning was displayed too long, but on the other hand, no accident happened, as it might have done if the cars had been allowed to go over the course at full speed despite the partial obstruction of the track.

The officials all performed their duties with admirable precision and all are deserving of commendation.

The timing and scoring were excellently done. The mechanical timer worked splendidly and the Quaker City Timers' and Scorers' Club under the direction of President Paul B. Huyette checked and posted the lap scores with much celerity and exactness.

The score-board was divided into squares representing each lap and the elapsed time was painted into the squares after it had been announced by megaphone to the press and the grandstands.

A few errors were made, but these were corrected almost instantly and by the time the last car had finished, the complete standing of all the contestants had been posted in detail on the board.

Best Laps at Fairmount Park

Fastest laps made by the cars in the Fairmount Park 200-mile road race. The length of the course is 8.1 miles according to survey and is not what is known as a fast course owing to the number of bends in its length.

Class 3-C

Wishart Says He Will Take an Appeal

Spencer Wishart, driver of Mercedes 17 in the Fairmount Park road race decided Monday, has declared that he will file an appeal with the Contest Board against the ruling of Referee Dunlap which disqualified his mount after the car had finished first in Division 5C. Wishart has until Thursday night to perfect his appeal.

NEWS of the WEEK CONDENSED

SYRACUSE, N. Y.—On September 30 foremen and assistant foremen of the H. H. Franklin Manufacturing Company held their annual clam bake at Pleasant Beach on Onondaga Lake, near Syracuse. Besides the clam dinner and the usual trimmings, baseball games and other impromptu sports helped make the day a very enjoyable one.

COLUMBUS, OHIO—The Charles Shiear Motor Car Company, Fourth and Spring streets, has taken the 1912 agency for the Hupmobile.

OMAHA, NEB.—The Auburn factory has just opened a branch here. W. T. Wilson will be the manager of the Omaha-Auburn Auto Company.

INDIANAPOLIS, IND.—O. H. Pearsall has been appointed general agent for Ideal motor trucks and has established quarters at 44 South Senate avenue.

OMAHA, NEB.—The E. R. Wilson Automobile Company has taken the agency for the Paige-Detroit car. The company at present handles the Lexington.

OMAHA, NEB.—The Marion Automobile Company has taken the agency for the Marmon cars. The company already has the Marion and Overland cars.

COLUMBUS, OHIO—O. G. Roberts & Company, 933 East Gay street, has closed contracts to handle the Marmon and Overland in nine counties in central Ohio for 1912.

BOSTON, MASS.—The S. G. V. agency is now located on Boylston street in the salesrooms formerly occupied by the Napier company, having moved from Ipswich street.

CONCORD, N. H.—The New Hampshire Automobile Company, of which W. E. Darrah is proprietor, has contracted to represent the Franklin Automobile Company this season.

ELMIRA, N. Y.—The Southern Tier Motor Company has been signed up by the Franklin Automobile Company as its representative in this locality. G. W. Shoemaker is president.

HARTFORD, CONN.—The Automobile Club of Hartford has undertaken the publication of a monthly magazine, to be known as *The Bulletin*. The magazine will make its initial appearance next month.

WILMINGTON, DEL.—The Bowe Carriage Company, of this city, has completed a fine automobile ambulance for the Phoenix Fire Company, which is ready for delivery and will be placed in service during the coming week.

SYRACUSE, N. Y.—A. A. Ledermann, formerly of Utica, has opened offices in the Rosenbloom building on South Salina street, where he will carry a full line of Pierce-Arrow automobiles and motor trucks.

ANDERSON, IND.—The Remy Electric Company has announced that $400 will be given the drivers taking first, second and third places in the Los Angeles-Phoenix great desert road race, November 4 and 6, 1911.

SYRACUSE, N. Y.—W. E. Hookway has formed the Hookway Motor Truck Company to handle the Atterbury line and the Reliance. Mr. H. T. Windel, formerly salesman for the Buick, is manager of the company.

GRAND RAPIDS, MICH.—The Moran Auto Sales Company has moved from its old location on Kent street to 91 Jefferson avenue, the garage formerly operated by the Riley Auto Company, whose stock has been taken over.

NEW YORK CITY—Fred P. Nehrbas, formerly connected with the Thomas Motor Car Company, has become factory manager of the American Locomotive Company's plant at Providence, where the Alco cars and Alco trucks are built.

COLUMBUS, OHIO—The Oscar S. Gear Automobile Company, 288 East Long street, has taken the agency in seven counties in Central Ohio for the Oldsmobile and Oakland for 1912. The Kelly truck will be represented in the same territory.

COLUMBUS, OHIO—The Cummins Auto Sales Company, 153-155 North Fourth street, has taken the central Ohio agency for the Elmore for 1912. Subagents have been contracted for as follows: Cambridge, E. O. Fogle; Thornville, D. S. Spangler.

RICHMOND, IND.—The following dealers have been given the agency for the Westcott line for 1912: Price Implement Company, Zanesville, Ohio; Ye Motor Shop, Connersville, Ind.; W. H. Miller, Champaign, Ill., and George J. Smith, Peoria, Ill.

DETROIT, MICH.—Joseph E. Warren has recently become connected with the Metzger Motor Car Company, of Detroit, manufacturers of the Everitt. Mr. Warren will be associated with Sales Manager Hood, in the capacity of chief of district managers.

BOSTON, MASS.—A 3-ton Board recently completed a 500-mile trip from Washington to this city in 4 1-2 days. The truck was finished just one day previous to the start of the trip. It carried 6,458 pounds of merchandise and ran on a schedule averaging 100 miles each day.

COLUMBUS, OHIO—The Reliance Truck & Garage Company, 111 East Lynn street, has closed contracts to handle all of the lines of the General Motors Truck Company, which will include electrics and gasoline trucks and delivery wagons. George Bohn is general manager.

ATLANTA, GA.—The Atlanta Automobile & Accessory Association held its annual banquet on Tuesday last. Plans were discussed for the holding of races on the Atlanta Speedway the day the Glidden tourists are in Atlanta, October 23, but nothing definite was done.

COLUMBUS, OHIO—Kimmell Brothers, 215 North Fourth street, have taken the agency in this section for the Speedwell and Empire for 1912. Subagencies have been contracted for the Empire as follows: Point Pleasant, W. Va., Edward L. Felson; Dayton, Ohio, Baker & Weaver.

PONTIAC, MICH.—The contract for a combination automobile chemical and hose wagon to cost $5,000 was awarded the American-LaFrance Company, of Elmira, N. Y., by the city commission. The wagon is to be built especially for the city's requirements and will be ready for delivery about the last of December.

NEW YORK CITY—William H. Chadwick has been appointed superintendent of the New York branch of the Locomobile Company of America. He will have entire charge of the mechanical and service departments. Mr. Chadwick was formerly with the Bosch Magneto Company, where he handled the repair and service departments.

OMAHA, NEB.—The dealers in Omaha took advantage of the Fall Ak-Sar-Ben carnival last week to have a garage show. All of the salesrooms were handsomely decorated, and special forms of displaying the cars were adopted. Automobile Row proved a rival to the street fair in attracting attention, and many cars were sold during the week.

PHILADELPHIA—Plans for a handsome two-story brick and terra cotta front clubhouse to cost in the neighborhood of $100,000 are being prepared for the Automobile Club of Philadelphia. The new home of the organization will be located at the southeast corner of Twenty-third and Ludlow streets, having a frontage of 136 feet and a depth of 152 feet.

FINDLEY, OHIO—The work of taking an inventory of the Findley Motor Company's stock under the direction of Receiver John M. Barr has begun and will probably take ten days. Coupled with this fact comes the announcement that eastern stockholders of the company are working out a plan for reorganizing the company, and that the same will be promulgated shortly after an inventory is filed.

WILKES-BARRE, PA.—J. H. Fleming, proprietor of the City Hall Garage, has been selected to handle the Matheson "Silent Six" cars in Scranton and Lackawanna county, Pa. On Saturday, September 30, a dinner was served at the Hotel Jermyn to the officers of the Matheson company and their guests, after which a general demonstration of all the Matheson "Silent Six" models was made.

MILWAUKEE, WIS.—The Chamber of Commerce has purchased a Buick light delivery car for its weighing and inspection department. Among the many advantages of motor service it has been found that with the truck samples of grain can be delivered on the floor of the chamber about one hour earlier than formerly, giving a big advantage to cash traders, to whom an hour a day is worth thousands.

NORWALK, OHIO.—The application for the transfer of the bankruptcy matter of the Norwalk Motor Car Company from Ben B. Wickham, referee for Huron county, to some other person on the ground that he is a stockholder in the company and an interested person, was acted upon favorably by Judge Killets, at Toledo. The judge appointed Frank E. Seager, of Fremont, referee in bankruptcy for Sandusky county, to have charge of the matter.

GRAND RAPIDS, MICH.—Grand Rapids' Third Annual Automobile Show is scheduled for February 14-15-16-17, 1912. By the selection of these dates it will again be possible for exhibitors at the Chicago show to come directly to the Grand Rapids exposition. The show will be held either in the Klingman building, as heretofore, or in the new Coliseum. C. L. Merriman, of the Herald Publishing Company, will have charge of space allotments.

TOLEDO, OHIO—The big addition to the Willys-Overland Company's plant at Toledo is nearing completion. The new building is four stories high, 300 feet wide and 400 feet long and of concrete construction. It was expected that with the completion of this addition all Overland cars could be constructed in Toledo, but an announcement has been made that the concern has been forced by the volume of trade to continue operations at the Indianapolis plant.

BUFFALO, N. Y.—The local Automobile Trade Association gave Mr. Norman E. Oliver a farewell dinner at the Automobile clubhouse Saturday, September 30. Mr. Oliver has been manager of the Diamond Rubber Company, of Buffalo, for the past ten years and has been promoted to secretary and general manager of the New York branch of the Diamond Rubber Company, which covers the States of New York, Pennsylvania and New Jersey.

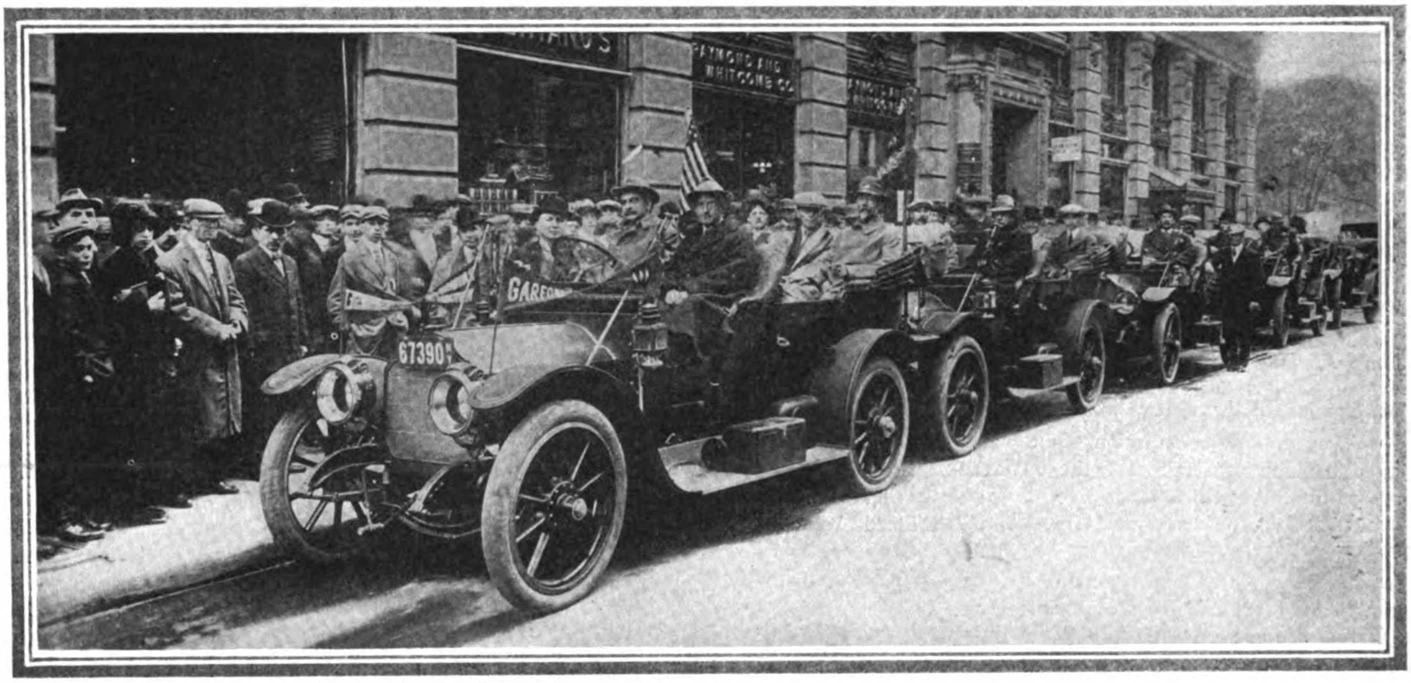
SIOUX CITY, IA.—A two-days' race meet will be held by the Sioux City Automobile Club October 20 and 21. Entries will close October 15. Each day there will be a 10-mile race for cars with a displacement of 161 to 230 inches, another for cars of 231 to 300 and a third for cars of 301 to 450. The first day there will be an Australian pursuit race and a 25-mile free-for-all. The second day there will be a 50-mile free-for-all. A total of $1,525 in prizes has been offered.

SYRACUSE, N. Y.—From data received by the Automobile Club of Syracuse the estimate of the number of automobiles under operation in this country is given at 500,000, representing an estimated outlay of $500,000,000. It is estimated that New York State has 50,000 machines. Pennsylvania is given second place, being accredited with from 40,000 to 50,000. Nevada and New Mexico are credited with the fewest number of automobiles, each having about 200 cars.

LANSING, MICH.—The Reo plant has resumed operations following the annual inventory. General Manager Richard H. Scott is authority for the statement that contracts with deposits have been closed for 10,243 cars to be delivered during the coming year, and he also states that the list of agencies has been increased 100 per cent. over that of last year. The report rendered at the annual stockholders' meeting of the company shows a surplus of $1,250,000, with $1,000,000 in cash on hand.

LANSING, MICH.—At the annual meeting of the board of directors of the Reo Motor Truck Company a 10 per cent. dividend was declared. During the past year certain parts of the truck have been manufactured

P. E. Sands and the Flanders "20," which won the "First to Hazelton" medal of the Pacific Highway Association, going 1,000 miles over a practically roadless country



Line-up of Garford cars at New York before they started on the trans-continental trip under the auspices of a well-known tourist agency

at the Reo factory, while other parts have been built at the plant on South Grand avenue formerly occupied by the Bement company. Hereafter the entire truck will be constructed and assembled at the Grand avenue factory, and it is estimated that about 500 men will be employed in this branch.

MINNEAPOLIS, MINN.—The Baker Electric is to be handled here by M. L. Hughes and A. H. C. Dalley in the twin cities and the Northwest.

KANSAS CITY, MO.—The A. J. Davies company, distributors for the Knox and Chadwick cars has taken the agency for the Bergdoll car.

PITTSBURGH, PA.—Director Howard B. Oursler, of the Department of Supplies, has bought three more auto propelled combination chemical and hose trucks to be delivered December 1st.

OKLAHOMA CITY, OKLA.—Makers and dealers having failed to support the proposed reliability run under the management of the Oklahoma State Automobile Association, it has been decided to call the event off.

MINNEAPOLIS, MINN.—The date for the hill climb to be held under the auspices of the Minneapolis Motor Club has been definitely fixed for October 21, weather permitting. It will take place on the Columbia Heights hill.

KANSAS CITY, MO.—C. E. Christian has taken charge of the Hupmobile branch and has removed to 3013 Main street. The Hupp-Yeats Electric branch has removed to the large and handsome quarters formerly occupied by the Detroit Electric branch at 3501 Main street. W. N. McWade, of Detroit, is the manager of the local branch of the Hupp-Yeats concern.

COLUMBUS, OHIO—Ohio and Indiana E. M. F. and Flanders automobile dealers to the number of 150 left recently via the T. & O. C. Railway on a special train consisting of nine Pullman cars for a two days' outing at Detroit as the guests of the Studebaker Automobile Company. The Twyman Motor Car Company, Columbus, representatives of the Studebaker Corporation, sent eighty of their dealers on the trip. The party will visit the ten Studebaker plants in Detroit and neighboring towns.

TOLEDO, OHIO—Automobiles will be pressed into service by the United States Government at Toledo for the purpose of conveying mail carriers in the business district to the starting point of their routes, thus saving all annoying delays which might otherwise result when the postal business is housed in its new post office some distance from the business section. The auto service will be inaugurated as soon as the main office is changed to the new building, which will be within the next few weeks.

INDIANAPOLIS, IND.—The Rajah Auto Supply Company recently brought suit in the Federal Court in Indianapolis against George F. Kreitlein, operating under the name of the Guarantee Tire & Rubber Company and the Dealers' Auto Supply Company, alleging Kreitlein was manufacturing and selling a spark plug infringing on patents covering the Rajah plug. Kreitlein has filed an answer, denying the allegation and stating that no less than eleven brands of spark plugs are on the market which are similar to the type manufactured by the Rajah company.

MILWAUKEE, WIS.—Albert Smith, 169 West Water street, representative of the Palmer-Singer in this territory, and for many years a well-known electrical man, died after a short illness, aged 48 years. Mr. Smith's death is attributed directly to a bantering wager with George Harvey, of Cleveland, Ohio, that he could drive from Milwaukee to Cleveland in two days' time without extra effort. With Mr. Harvey as a passenger, Mr. Smith easily won the wager in a two-passenger Palmer-Singer, but in doing so he contracted pneumonia, which resulted fatally within a week.

WILMINGTON, DEL.—A new law enacted by the General Assembly of Delaware this year for the protection of motor vehicles is to be given its first test at the November term of the court of General Sessions in and for New Castle county, in which Wilmington is located. This is a special law intended to put a stop to joy riding. For some time there had been a law on the statute books making it a punishable offense to drive off a horse without the consent of the owner, but automobilists had no such protection, but they have now and naturally there is some rejoicing. An arrest has recently been made and a test case will be tried.

INDIANAPOLIS, IND.—Judge Albert B. Anderson of the United States Circuit Court here has entered a decree enjoining Orion K. Stuart from obtaining empty Presto-O-Lite and Autogas tanks and refilling them for the purpose of putting them on the market. Judge Anderson has also referred the matter to Edward Daniels, master in chancery, who is to determine the amount of damages the Presto-O-Lite company has suffered by Stuart having filled such tanks. The decree also finds that the Autogas company has manufactured tanks infringing on the patents of the plaintiffs and that Stuart refilled tanks manufactured by the Autogas company.

Automobile Incorporations

AUTOMOBILES AND PARTS

ALEXANDRIA, VA.—B. F. Board Motor Truck Co.; capital, $25,000; to make freight automobiles. Incorporators: B. F. Board, Douglas Stuart, W. E. Bain, George S. Hinkins.

BROOKLYN, N. Y.—Osgood Motor Car Co.; capital, $10,000; to deal in automobiles. Incorporators: Samuel H. Misleind, Paul W. Smith, Irving J. Joseph.

BUFFALO, N. Y.—Baker Bros. Motor Co.; capital, $10,000; to deal in motor cars. Incorporators: Edward A. Green, Edward H. Baker, Clarence W. Baker.

MONTREAL, CAN.—Dunnings Limited; capital, $20,000; to deal in automobiles.

NOVATA, OKLA.—Nowata Motor Car Co.; capital, $2,500; to sell automobiles. Incorporators: Walter K. Campbell, George Gordon, Stanley J. Campbell.

OAKLAND, CAL.—S. & D. Motor Vehicle Co.; capital, $280,000; to deal in automobiles. Incorporators: B. E. Duckworth, A. A. Montague, Carlos Schmidt.

PEORIA, ILL.—Cadillac Automobile Co.; capital, $5,000; to sell automobiles. Incorporators: Rollin Travis, Henry Numann, H. H. Moody.

PROVIDENCE, R. I.—Providence Motor Car Co.; capital, $25,000; to deal in automobiles. Incorporators: John A. McDonald, Wm. H. McSoley, Alice Stanton.

RICHMOND, VA.—Grasberger Vehicle Co., Inc.; capital, $50,000; to deal in pleasure and freight automobiles. Incorporators: J. A. Grasberger, J. F. Sorg, Robert N. Wildbore.

RICHMOND, VA.—Motor Truck Co.; capital, $25,000; to sell freight automobiles. Incorporators: H. A. Gillis, Charles Laurens, T. M. Garrity, E. P. Cox.

AUTOMOBILE GARAGES, ACCESSORIES,

BUFFALO, N. Y.—Buffalo Reliable Garage; capital, $2,000; to conduct a general garage business. Incorporators: John J. Timmerman, Irving L. Carpenter, Charles H. Cutting.

BUFFALO, N. Y.—Kunz-Adams-McNamara Co.; capital, $10,000. Incorporators: H. M. Adams, William Kunz, O. B. McNamara.

CLEVELAND, OHIO.—Richardson-Neighbors Motor Co.; capital, $5,000; to sell accessories. Incorporators: F. E. Richardson, H. F. Neighbors; W. J. Dawley, Sidney Seidman, Stephen M. Young.

DAYTON, OHIO.—Acme Carbureter Co.; capital, $10,000; to manufacture carbureters and other accessories. Incorporators: Chas. S. Barkelew, E. Leiber McCallay, Chas. C. Margerum, W. H. Johnson, Lester Corson.

DAYTON, OHIO—Baker Taxicab Co.; capital, $10,000; to operate a garage and taxi business. Incorporators: George L. Baker, Frank R. Baker, Harry W. Baker, John N. Van Deman, Chas. D. Heald.

ELMIRA, N. Y.—Heater-Muffler Co.; capital, $50,000; to manufacture appliances for automobiles and engines. Incorporators: Wilber Kinzzie, Lanson D. Curran, Ansel G. Ingham.

INDIANAPOLIS, IND.—Merchants Auto Co.; capital, $50,000; to conduct a garage business. Incorporators: E. Darrow, Wm. E. Burk, Chas. S. Shotwell, H. H. Rice, C. L. Marshall, W. A. Atkins, Harvey B. Stout.

NEW YORK, N. Y.—Manhattan Top & Body Co.; capital, $50,000; to manufacture automobile equipments. Incorporators: Guy B. Radford, Herman Schuler, Chas. D. Heintze.

UTICA, N. Y.—Divine Tire Demonstrating Co.; capital, $10,000. Incorporators: Bradford H. Divine, Edmund G. Munson, T. Harvey Ferris.

NEW YORK CITY—A. R. Mosler & Co., are erecting a new factory at the corner of Wakefield and Webster avenues, Wakefield Park, New York City. The new building is constructed of brick and concrete, 100 x 150 feet and is two stories high. Two hundred and fifty people will be employed.

INDIANAPOLIS, IND.—Another three-story reinforced concrete building is being added to Auto Row, in North Capitol avenue, by the Globe Realty Company. It will cost $60,000 and will be completed February 1. The building will be occupied by the Henderson Motor Sales Company and the B. F. Goodrich Company's tire sales branch.

MINNEAPOLIS, MINN.—A show coliseum for Minneapolis, which is to be completed by next January in time for the automobile exhibition, was assured last Tuesday when the Board of Tax Levy appropriated $25,000 for an annex to the National Guard Armory in this city. When completed the entire building will hold more than 9,000 people, and will have a floor space of 72,000 square feet.

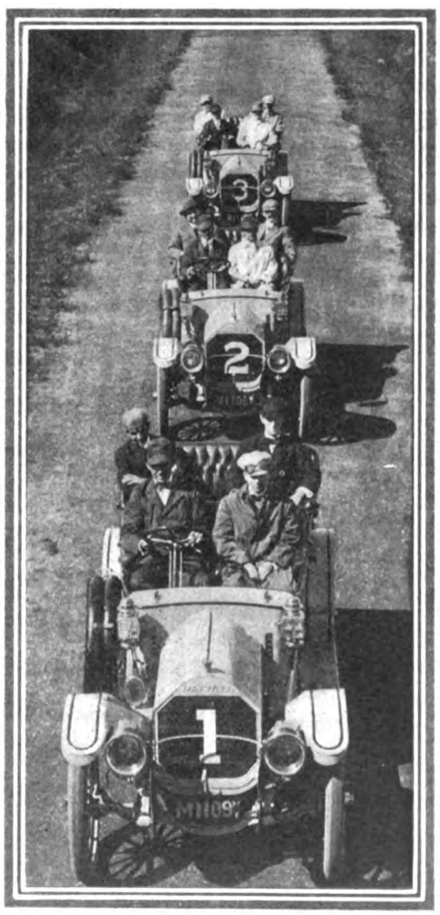
SOUTH BEND, IND.—One of the first steps taken by the city to install motor vehicles in all the fire stations during the next few years has been taken by the City Council appropriating $6,500 with which to purchase an automobile chemical engine. The Board of Safety has received specifications prepared by Fire Chief Wilfrid Grant, and will ask for a machine to conform to the plans of the chief.

MINNEAPOLIS, MINN.—On its return to the list of Minneapolis-sold cars the Marion makes its home with the new Marion Motor Car Company, 1027 Hennepin avenue. The company is officered by men old in the business. W. A. Crowe is president; W. A. Crowe, Jr., is vice-president; H. A. Crowe is secretary-treasurer. C. G. Wernicke, of Minneapolis, is sales manager.

BOSTON, MASS.—The Cork Insert Company announces that a reduction in the royalty charged for the right to use cork inserts in automobile clutches and brakes has been made. The royalty charged is now 90 cents on clutches transmitting less than 25 horsepower and $1.25 on clutches transmitting 25 horsepower or more, and 50 cents per vehicle for brakes.

CINCINNATI, O.—The announcement is made here that the Kruse Motor Car Company will hereafter control the complete line of Maxwell bodies and chassis, for this city, contracts to that effect having been concluded, and arrangements made, to become operative at once. The first specimens of the 1912 Maxwell, will soon be on exhibit at the Kruse Warerooms, on Seventh avenue.

NEW HAVEN, CONN.—The White Motors Company, which sells White cars and trucks in Connecticut, until recently located at 666 State street, has opened a handsome office and salesroom at 1004 Chapel street, where a complete line of the White Company's products will be carried. The officers are: P. R. Greist, president; H. M. Greist, treasurer, and W. A. Rutz, secretary and general manager.



Maxwell team which will represent Tarrytown, N. Y., in the Glidden tour—No. 1, Harry Walls; No. 2, E. G. Gager; No. 3, Thos. Costello

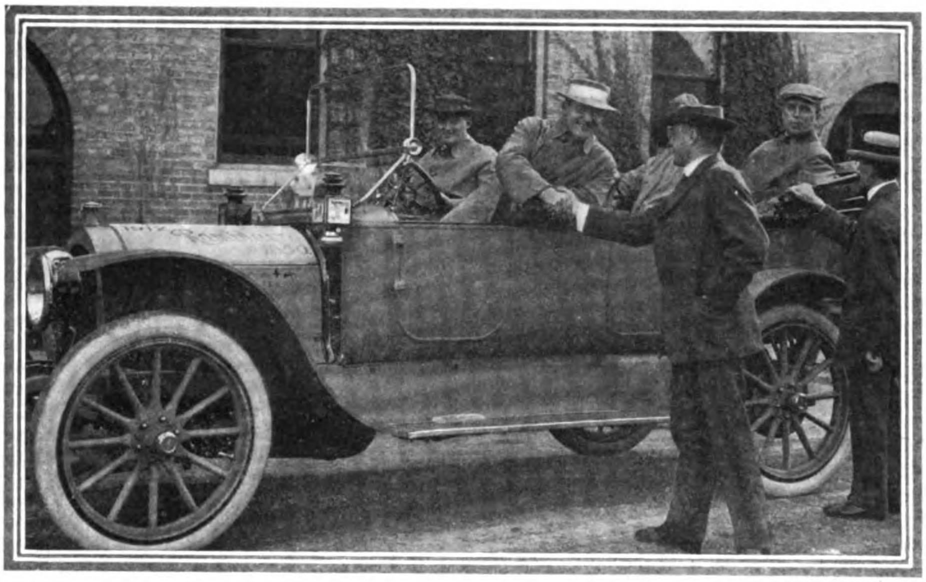
RACINE, WIS.—The motor car department of the J. I. Case Threshing Machine Company has started construction work on a new building to replace a large frame structure situated between Twenty-third and Twenty-fourth streets.

PITTSFIELD, MASS.—The Cortland Motor Wagon Company has moved its plant from Cortland, N. Y., to this city, in order to secure better shipping facilities. The new plant has a floor space of 50,000 square feet, and while the machinery has not yet been completely installed the management expect to have the manufacture of 1500-pound and one-ton trucks under way within a week.

BOSTON, MASS.—George W. Houk, manager of the New England branch of the Oldsmobile Company, with headquarters in Boston, has resigned and his successor is W. B. Fewell. Mr. Houk has not decided on his future plans, but he is considering an offer to go to London to manage a branch there. He spent several years in England previous to coming to Boston two years ago.

MILWAUKEE, WIS. — Manufacturers of motor vehicles are granted the lowest rates of all in the list arranged by the Employers' Mutual Liability Insurance Company of Wisconsin, organized to insure manufacturers against the hazards of the new workingmen's compensation or industrial insurance act passed by the Wisconsin Legislature and now in force. The rate per $100 of wages is fixed in a large number of cases and for motor manufacturers is 67 cents for Class A, 75 cents for Class B and 84 cents for Class C. The next lowest class pays 66 2-3 per cent. more.

OF INTEREST to the INDUSTRY



KENOSHA, WIS.—There left the Rambler factory on Tuesday, October 3, the flagbearer of the Rambler line for 1912, which is to be relayed through the East by representatives of that company in the various cities on the route. The car was manned on the first lap by Walter R. Simkin, of Chicago, and Al Reeke, of Milwaukee, who drove it to Chicago, where Webb Jay took the wheel. In the illustration Charles T. Jeffery, president of the Thomas B. Jeffery Company, is seen bidding the first crew Godspeed.

BOSTON, MASS.—George L. Cooke has been appointed manager of the local agency for the Morse car.

BOSTON, MASS.—Lin McKie has been given charge of the Velie truck sales and maintenance in the Boston territory.

PHILADELPHIA—The local agency of the Krit car, the Kline-Krit Company, has been moved to Nos. 1405-1407 Race street.

BOSTON, MASS.—W. Mason Turner will represent the Amplex car here. He has secured quarters at 261 Dartmouth stret.

COLUMBUS, OHIO—F. E. Avery, 1199 Franklin avenue, has taken the central Ohio agency for the Packard and the Waverley Electric.

ATLANTA, GA.—The Velie Motor Company will soon open a branch in Atlanta. This company has secured a location at 447 Peachtree street.

MONTREAL, CANADA—The Motor Import of Canada, Ltd., have been appointed sales agents in the Province of Quebec for Pierce-Arrow motor cars.

ATLANTA, GA.—Hupp-Yeats Electrics and R. C. H. cars will soon be sold from their own branch in Atlanta, the new store at Peachtree and North avenue being now nearly completed.

INDIANAPOLIS, IND.—A factory sales branch of the Auburn Automobile Company was opened at 518 North Capitol avenue on October 2, with F. P. Bellinger in charge as manager.

BOSTON, MASS.—The Nance Six is a newcomer to Boston motor circles and salesrooms for it have been opened at 94 Massachusetts avenue. It is being handled by the Motor Car Company, recently organized.

MILWAUKEE, WIS.—The Lozier Motor Sales Company, 197-199 Ogden avenue, State distributor for the Lozier, has been appointed agent for the Marion, which heretofore has been represented by George W. Browne, 460 Milwaukee street.

BOSTON, MASS.—The Teel Manufacturing Company, of Medford, one of the suburbs of Boston, a concern that has been building wagons and automobile tops for years, has embarked in the commercial truck field and is now manufacturing a 5-ton vehicle.

KENOSHA, WIS.—Frederick Purdy, for many years a foreman in the shops of the Thomas B. Jeffery Company, has purchased the interest of the Kent Brothers in the Kent Motor Car Company and will henceforth conduct the garage on Church street.

GREEN BAY, WIS.—Lawrence Kittell and Charles W. Collier have formed a partnership under the style of Fox River Motor Car Company and will handle the Ford in this territory. A garage and salesrooms have been opened at 510-512 South Monroe street.

COLUMBUS, OHIO—The Board of Education has purchased a motor car for the use of Superintendent J. A. Shawan of the public schools. The car is to be at the disposal of the members of the Board of Education also when they are on official business.

MONTREAL, CANADA—The liquidators of the National Motor Car Company of Canada, Ltd., are calling for tenders for the sale of the business, which consists principally of stock in trade, furniture, fixtures, machinery and tools, the whole valued at $3,971.24.

MILWAUKEE, WIS.—The Wisconsin Auto Sales Company has been appointed Wisconsin distributor for the National, Cutting, Herreshoff and Westcott cars. The company has temporary headquarters at 114 Mason street in the Colby-Abbott building.

KANSAS CITY, MO.—W. S. Hathaway, general supervisor for the United States Motor Company has decided to retire from the automobile business. Mr. Hathaway represented the Buick company in this city for four years and the United States Motor Company the same length of time.

BOSTON, MASS.—C. F. Whitney, who handles the Alco in Boston and who had the Stoddard-Dayton until a week ago, has vacated the quarters on Commonwealth avenue and has moved downtown to Boylston street in Copley square. The Alco plans to establish its own branch in Boston.

PITTSBURGH, PA.—The Universal Motor Truck Company, of Warren, Ohio, which was formed in Denver a few years ago, is considering a change of location. Its officials have been considering Fairmont, W. Va., as a new home for the plant, which will employ 500 skilled workmen.

PITTSBURGH, PA.—The Penn Motor Car Company, which established a plant about a year ago in the East End and in which A. G. Breitwieser, a wholesale lumberman of this city, is largely interested, has finally decided to locate its immense plant at New Castle, Pa., 30 miles north of here. It has secured 9 acres of ground, 4 of which will be covered with buildings, it is announced. The initial investment for building and machinery will be about $350,000.

HAMILTON, ONTARIO — The Schacht Motor Company, of Cincinnati, Ohio, has purchased the plant of the Tilden-Jackson Typewriter Company, Hamilton, Ont., and has organized a Canadian company to manufacture commercial motor vehicles in Canada. The officers of the company are: President, Thomas P. Rolph, Toronto; vice-president, T. H. Schacht, Cincinnati; treasurer, Gerrard Muntz, Toronto; secretary and sales manager, J. S. Innes, Toronto.

PATENTS GONE TO ISSUE

CLUTCH MECHANISM—Motion is transmitted by means of a plurality of friction surfaces.

2. In the clutch shown in Fig. 1 a driving member is mounted on a shaft and having friction bearing surfaces thereon, while a driven member longitudinally slidable along the same shaft is provided and locked against rotation relatively thereto. A friction shoe is longitudinally movable along the shaft, another friction shoe radially, and independent yielding means are interposed between the driven member and the two friction shoes, so that, when the driven member is moved longitudinally and radially of the shaft, the shoes may be moved longitudinally and radially of the shaft respectively, and forced against the friction bearing surfaces on the driving member with a yielding pressure.

No. 1,004,940—To Frederick A. Thurston, assignor of forty-eight one-hundredths to Henry Mayberry Jones, both of Lynn, Mass. Granted October 3, 1911; filed July 19, 1910.

ACETYLENE GENERATOR—A plant for generating acetylene gas.

The invention which is protected by this patent consists in the combination of a carbide holder with, and mounted on top of, a generating tank; from this holder a pivoted feed-shoe is suspended which normally tends to assume a non-dumping position. A gasometer bell is provided, also an actuating shaft for the feed shoe, the shaft having a crank on which a pivoted lever is pivotally mounted, the crank engaging a counterweighted hook. Pivoted lever and gasometer bell communicate through actuating connections, and there is provided on the carbide holder an interference device which, when moved to a position permitting the opening of the carbide holder, engages the counterweighted hook.

No. 1,004,909—to Paul A. Rose, Chicago, Ill., assignor to Acetylene Apparatus Mfg. Co., Chicago, Ill. Granted October 3, 1911; filed March 9, 1910.

LIGHT PROJECTOR—Containing a reflector and a Fresnel type of lens.

3. The patent relates to the combination (Fig. 2) of a casing and lamp with a lens of the Fresnel type. The inner edge of an outwardly flaring and reflecting hood meets and surrounds the operative face of the lens, and a glass is provided at the outer edge of the hood. The angle of the reflecting surface of the hood is such that the lights rays projected through the miters of the lens and caused by them to be diverged away from the axis of the beam are caught and reflected by this surface and collected into an approximately parallel beam.

No. 1,004,628—To William Churchill, Corning, N. Y., assignor to Corning Glass Works, Corning, N. Y. Granted October 3, 1911; filed September 14, 1910.

PISTON RING—Consisting of a packing ring and supplementary member.

4. This patent refers to the combination of a piston head, a face plate secured thereto (Fig. 3), a split packing ring and a supplemental packing member, the ring and member being located between the piston head and face plate. Means are provided to normally hold the packing member toward the cylinder wall on the side where the split is located in the ring, and also means to secure all the members against rotation.

No. 1,004,631—To Thomas Davis, Pittsburgh, Pa. Granted October 3, 1911; filed January 13, 1911.

RUBBER TIRE—Containing a plurality of resilient sections and an externally mounted retaining ring.

A greater number of the sections than normally required form a continuous circle of the diameter of the retaining ring, which holds the sections in a compressed state.

No. 1,004,642—To George H. Gillette, New York Granted October 3, 1911; filed November 28, 1910.

ELECTRIC WELDING—Method of fixing a pin or rod to a plate.

The process consists in forming a countersink in the end of the pin or rod and one or more projections extending beyond the outer wall of the countersink and in uniting the pin or rod to the plate by an electric butt welding operation.

No. 1,004,795—To Laurence S. Lachman, New York, assignor to Universal Electric Welding Co., New York. Granted October 3, 1911; filed October 15, 1908.

STEERING MECHANISM LOCK—Toothed bars serve to hold steering knuckle in place.

In the device covered by this patent (Fig. 4) a toothed bar is fixed to the front axle of an automobile, and a movable toothed bar is connected to a steering knuckle. Means are provided to force the teeth of the two toothed bars into engagement, so that the movable bar is locked against movement under the influence of the steering knuckles to which it is connected.

No. 1,004,973—To George W. Benton, Finley, N. D. Granted October 3, 1911; filed January 26, 1911.

PNEUMATIC TIRE RIM—A rim having flanges overlapping and bolted to the felloe. The rim patented fits around a wheel felloe and has a portion of it beveled, the rim having a tire flange and another flange contacting with the felloe. A removable flanged ring fits the beveled portion of the rim and has a tire holding flange and a flange in contact with the felloe, bolts passing through the flanges contacting with the felloe and nuts being used to secure removable ring and beveled ring in place on the felloe. Lugs carried by the removable ring project over the flanged nuts.

No. 1,004,639—to Sylvester Cline Force, San Francisco, Cal. Granted October 3, 1911; filed January 6, 1910.

Newest Ideas Among the Accessories

Speedo Air Valve

SPEEDO, shown in Figs. 1 and 2 serves to regulate the air supplied to the engine at all speeds or to feed finely divided kerosene to the motor, when the latter needs decarbonizing. The exterior appearance of the device is shown in Fig. 1, illustrating the manner of attaching the Speedo to the intake manifold of the motor.

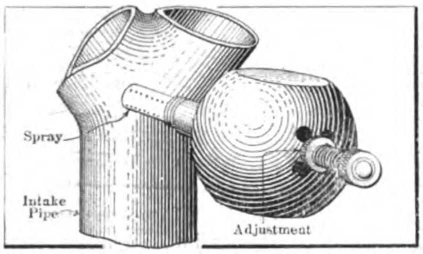

Fig. 1—Speedo auxiliary air supply on intake manifold

To install the Speedo it is necessary to drill a hole in the manifold at any suitable point above the carbureter and to tap it for 1-4-inch pipe thread.

After inserting the threaded stem of the Speedo in the opening made in the manifold, the nut marked for adjustment is loosened and the projecting stem of the device screwed inward as far as it may be advanced. It is necessary that in installing this accessory one flat side comes to the top position, so as to completely break up the gasoline molecules struck by the air entering the manifold from the Speedo.

The device having been installed, the engine is started and throttled down as low as possible; then the projecting stem is slowly screwed outward until the motor begins to pick up. At this point the retracting movement of the stem is stopped, the same is given a full turn in the inward direction and the adjustment nut locked tightly.

The Speedo now being ready for use, it will be well to examine Fig. 2 for an explanation of its operation. The casing is threaded at one end to fit into the manifold, twenty-eight holes being provided at that end of the stem, which is hollow and communicates with the inner space of the round portion of the Speedo. This portion is tapped to accommodate the projecting stem on which the air valve slides, the valve having an inner and an outer seating. If it falls on the latter, it covers up four holes serving as air intakes. The wall of the chamber in which the valve moves is tapered, so that as the valve is moved outward the space surrounding it increases.

The proper adjustment of the device insures a certain amount of spring tension, which tends to draw the valve away from its inner seat. When the motor is throttled down, the suction through the Speedo is naturally a comparatively great one, but it only tends to seat the valve more securely. If, however, the throttle opening is increased, the suction through the device decreases and is finally overcome by the spring tension, which then lifts the valve off its seat and permits air to pass through the Speedo into the manifold. The air leaving the outlet pipe crosswise in relation to the mixture traveling toward the motor strikes the gasoline molecules with a maximum of strength and breaks them up into finer parts. The effect of the Speedo and the air supplied by it to the motor increase with the engine speed.

If the Speedo is to be used for removing the carbon accumulated in the engine cylinders, kerosene is injected through it into the manifold. In this case a small rubber tube furnished with the Speedo and carrying at one end a brass connection is screwed onto the end of the projecting stem, after the cap shown in Fig. 2 has been removed for the purpose. The other end of the tube is made to hang down into a vessel containing one pint of kerosene, and if the motor is started, the oil is drawn into the hollow projecting stem, atomized through the nozzle formed by the inner end of this stem and mixed with the charge flowing from the carbureter to the motor. One pint of oil applied twice a month will remove the carbon settling in the cylinders during this time. This device is made by the International Accessories Corporation, of New York, Chicago and Los Angeles.

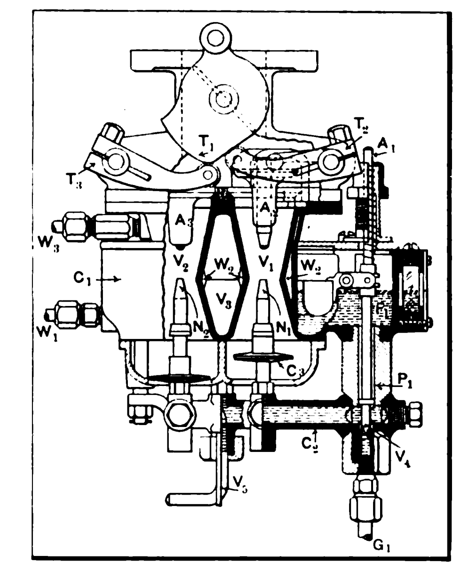

Fig. 2—Section showing details of C R G carbureter

C R G Carbureter

The special feature of the C R G carbureter shown in Fig. 3 is the fact that use is made in it of three Venturi tubes which are assembled in one casing C1 of the carbureter. These Venturi tubes V1, V2 and V3 have a gasoline nozzle concentrically located in each of them, as shown at N1 and N2, situated in V1 and

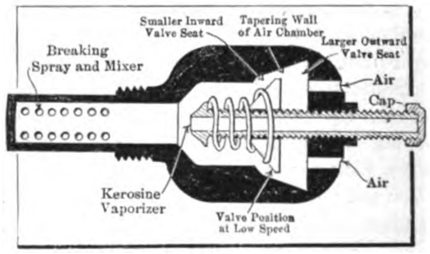

Fig. 2—Section showing principle of Speedo operation

V2 respectively. The nozzles are screwed into the gasoline connection C2. The gasoline enters at G1, fills the space of the connection C2 and then rises through pipe P1 to the float chamber F1 which surrounds the Venturi tubes on all sides. The gasoline flow is regulated by the needle valve V4, adjustable at A1, and after rising to a certain level in the float chamber the gasoline flows back into C2 to the nozzles, lifting the clappet valve C3 from its seating and permitting the fuel to flow into Venturi tube V1. The air is supplied through the seats of the clappet valves, when these are lifted through the suction of the motor.

In the operation of this carbureter, V1 is the Venturi tube which first comes into play. The throttle cam T1 operates the throttle lever T2, and opening the throttle position by the lever on the steering wheel moves the throttle cam in the direction indicated by the arrow, thus relieving the air valve A2 of the pressure holding it down and creating in the tube V1 a partial vacuum which lifts clappet valve C3 and permits gasoline and air to enter the Venturi tube. The needle valve V5 serves to adjust the flow of gasoline to a minimum at the slow speeds of the motor. If the position of the throttle cam T1 is advanced further, the second air valve A3 and the corresponding Venturi tube V2 are brought into action, giving the motor an additional supply of gasoline and air, the proportion of which, however, remains unaltered. Likewise, advancing the throttle cam to its ultimate position brings the high-speed Venturi tube V3 into play.

The C R G carbureter is manufactured by the C R G Manufacturing Co., Saugus, Mass.

VOL. XXV NEW YORK—THURSDAY, OCTOBER 19, 1911—CHICAGO NO. 16

THE AUTOMOBILE

Only Two Teams Perfect in Glidden

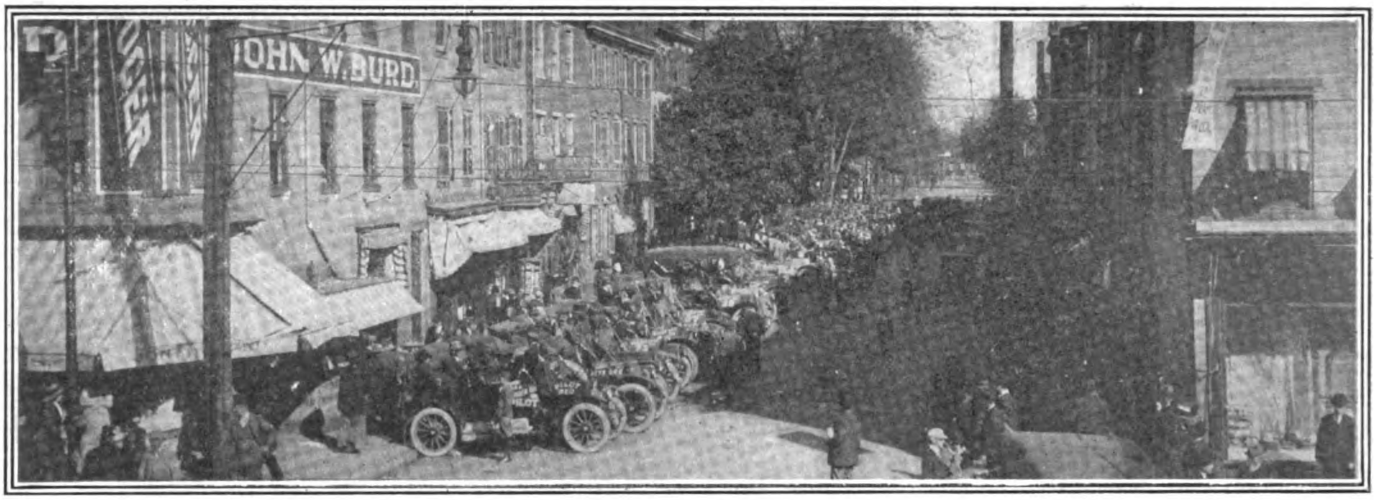
The Start of the Glidden Tour from New York, the Maxwell Team Waiting at the Line

Governor Hoke Smith, of Georgia, and Governor Woodrow Wilson, of New Jersey, Tourists on the First Day's Run

ROANOKE, VA., Oct. 17—Special Telegram—Mud and hospitality combine to make the Glidden tour up to this city one of intense interest to those who are accompanying it through the vicissitudes of the route. There is a unanimous opinion current among the tourists that the contest is sufficiently eventful to satisfy the cravings for excitement and discomfort of the most exacting. The invitations which pour in amply uphold the reputation of the hospitable South and go far in alleviating the dismal feelings and thoughts inspired by the tropical downpour which has met and all but conquered the Glidden tour.

Four days of the tour are now past, and in the expectations of all the worst is yet to come as far as the condition of the roads is concerned, as the rain is falling heavily over the districts through which the tour is scheduled and there is no apparent relief in sight. Many of the tourists are of the opinion that a delay will be necessary to allow the streams to sink back to their normal level after the terrible rains of to-day. The fords are in many cases so high that the magnetos are flooded whenever an attempt is made to cross them; while in other cases the roads themselves are gushing streams.

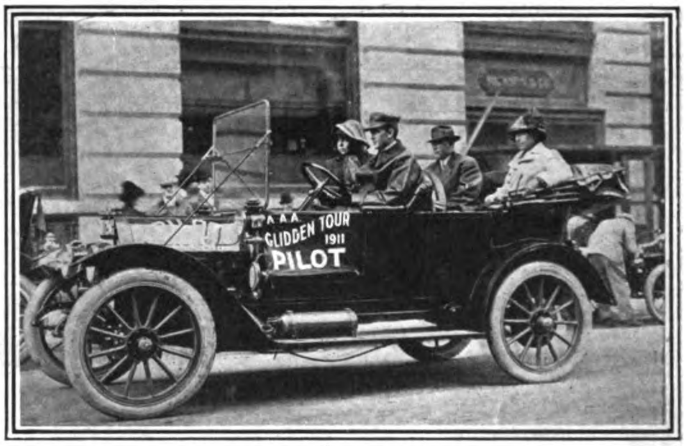
Engine troubles have been few, nearly all the delays being directly traceable to the heavy roads through which the cars have bravely struggled and the number of perfect scores is remarkable when the stringent conditions which have arisen are considered. Many teams have imperfect scores owing to the fact that one of the cars in the team fell a victim to the heavy going of to-day while the other two managed to reach the control to-night on time, which is all that is required to escape penalization. There are now but two teams remaining with perfect scores; they are, the Tarrytown team consisting **of three Maxwell cars and the Waltham team composed of three Metz machines. To-day's run was responsible for the slaughter of the perfect scores, that part of the road from Natural Bridge to this city doing the**



Gliddenites in the checking station at Trenton, N. J., on first day's tour

work. Had it not been for the cloudburst all would have been well.

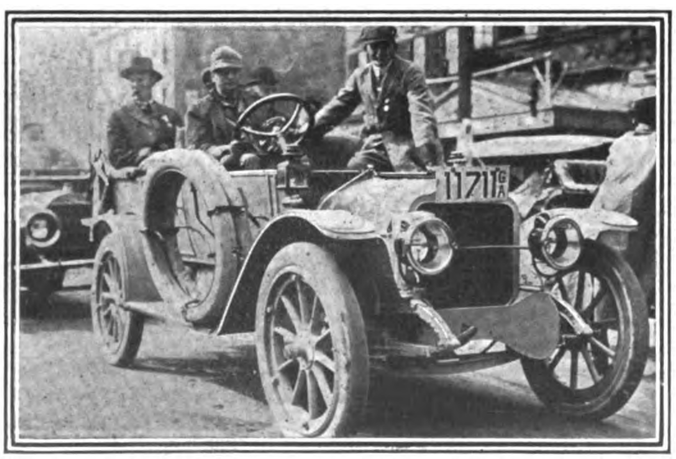
Up to a late hour to-night the following cars had not checked into the Roanoke night control: No. 6, Thomas; No. 8, Flanders; No. 14, White; No. 18, Garford; No. 29, Cadillac; No. 42, E-M-F; No. 50, Maxwell; No. 55, Flanders, and No. 71, Case. The following penalties have up to this hour been announced on the other cars for to-day's run; No. 33, Cole, 87 points; No. 41, Winton, 21 points; No. 43, Ford, 125 points: No. 4, White, 4 points; No. 47, Cadillac, 23 points; No. 51, Cadillac, 13 points; No. 52, Packard, 14 points; No. 56, Marathon, 72 points; No. 58, Marathon, 9 points; No. 59, Cadillac, 5 points; No. 60, Oldsmobile, 4 points; No. 61, Flanders, 7 points; No. 64, Pierce-Arrow, 3 points; No. 66, Stevens-Duryea, 10 points, and No. 69, Oldsmobile Autocrat, 1 point. The majority of these penalties, it is understood, have been imposed for lateness due to the wretched condition of the roads.



R. M. Owen in the Reo Pathfinder on tour

Perfect Scores Slaughtered

Roanoke, Va., Oct. 17—Special telegram. To-day was the real Waterloo of the 1911 Glidden tour, at least so far as it has progressed. The tour to-day staggered, tottered for a moment and went on, but it was a spattered remnant of the proud array of automobiles that left New York last Saturday that limped into night control at Roanoke. A cloudburst, such as has not been seen in this section for 20 years, overwhelmed the tour this afternoon and plucked clean scores by the dozens. The scene of the convulsion of nature was in the north end of Roanoke Valley, just south of Natural Bridge. For an hour the rain fell solidly and when it ceased to the volume of a mere downpour roads were under water. As a result there will probably be no run to-morrow because creeks are running bank full and fords are impossible if deep enough to flood the magnetos.



Major Cohen of Atlanta in his White car

Along the way from Natural Bridge contesting cars are lying to-night in the blinding rain abandoned by their crews or are limping towards Roanoke. Nine cars failed to report at night control up to its closing time and fifteen cars were penalized for lateness. President Hooper's Garford non-contestant is in the ditch 17 miles from this city; and accidents were so frequent that they are not being considered individually. Fortunately nobody received serious injuries. There would have been but few clean scores left to-night had it not been for an allowance of 26 minutes made to the running time of each contestant by Referee Walker. The grounds for the allowance rest upon the blockading of the road by two automobile fire engines proceeding toward Roanoke. These engines became mired and held back the procession materially.

The route to-day was from Staunton through the Shenandoah valley to Lexington, with a detour to Lee and Jackson's tombs and the Virginia military institute. Noon control was at Natural Bridge.

The going was poor most of the way into noon control and from Natural Bridge to a point 10 miles from Roanoke they were beyond description under the circumstances. Red clay is the road bed and a pedestrian simply could not stand upon it. The road is narrow and once a car, with a fast schedule, got behind time it was almost worth human life to try to regain position.

Penalizations imposed upon the participants during the first four days of the tour are given in the following table:

Team	No.	Car.	Penalties by days. 1	2	3	4	Total
Tarrytown	1	Maxwell	0	0	0	0	0

*Not reported at night control.

Atlanta men in Corbin on the Glidden tour

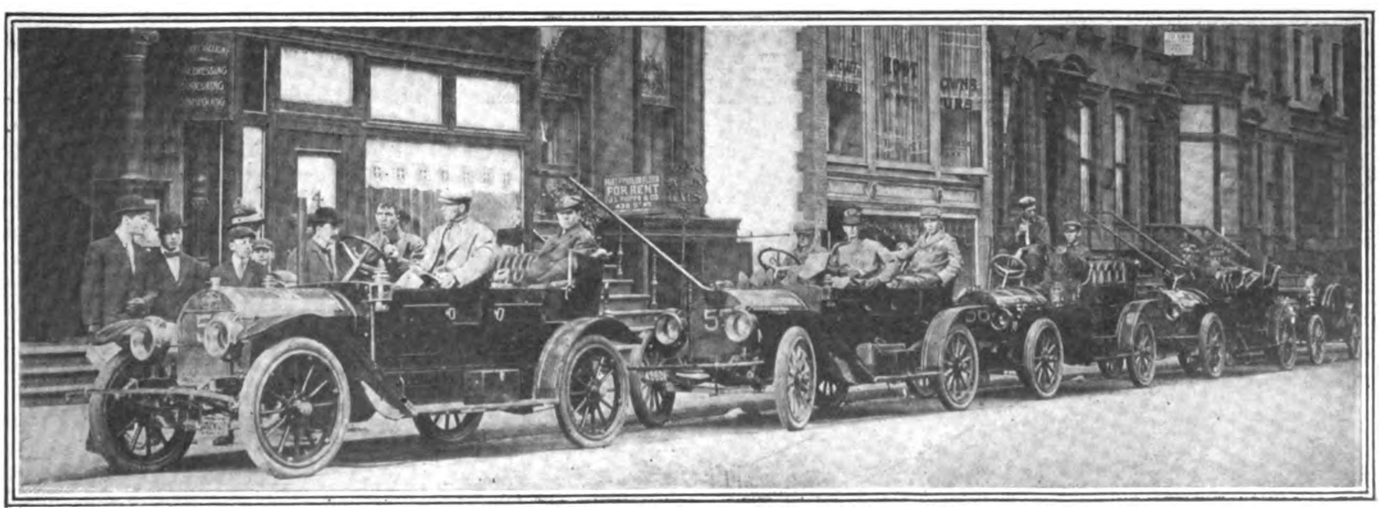
One of the Flanders cars in the Glidden

The First Day's Run

PHILADELPHIA, PA., Oct. 14—The first day's running of the Glidden tour failed to produce any penalizations, all contestants checking into noon and night controls within their schedules.

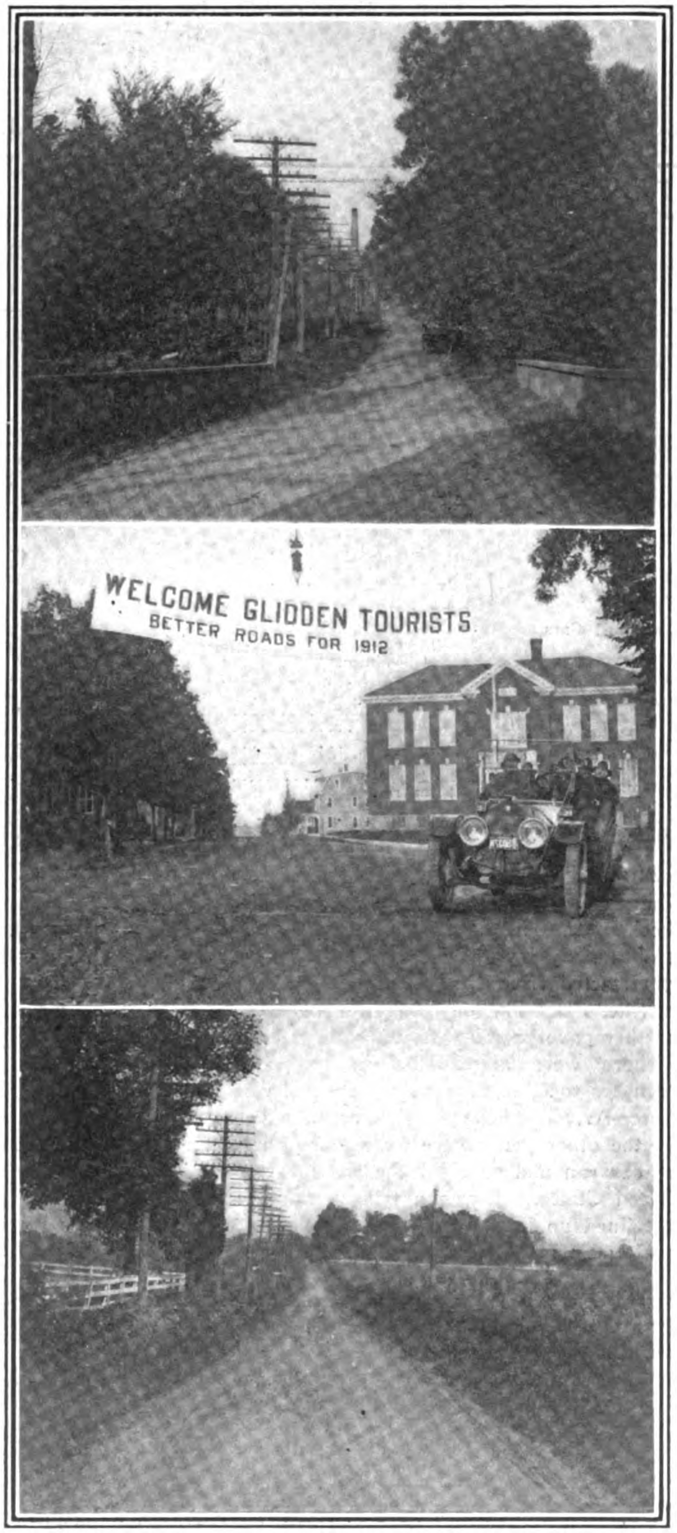
With sixty-four contesting cars in line, the Glidden tour of 1911 started from New York this morning on its way to Jacksonville, Fla. The day was fair overhead, but the recent dry weather gave promise of much dust.

There were automobiles in the column that have been strangers to Glidden tours for several years, among them being Pierce-Arrow, Packard, Thomas, Stevens, Winton and others. On the other hand there were many cars of moderate price in the caravan and some of the smallest automobiles made in the United States. It was a typical exhibition of American cars that lined up in West Thirty-ninth street, facing Fifth avenue in New York at the start.



The team of three Marathon cars from Nashville, Tenn., waiting for start of the tour

Glidden Tour Road Scenes



These are typical views of the roads through Pennsylvania and New Jersey on the first day's run of the Glidden Tour. The New Jersey roads are proverbial for their excellent condition. The two lower illustrations are Pennsylvania scenes, the middle one being near Gettysburg and the bottom one in the vicinity of Lanhorn. The State of Pennsylvania has built miles of good stone road within the last 5 years, but the great problem has been that of keeping the surface in a good state of repair. It is one thing to build a good road and it is another problem to keep the road in a proper condition. To-day the maintenance problem is the big one in the road building field.

Behind the wheels of the cars were millionaires, business and professional men, representing the most progressive element of the New South, factory drivers of tried ability and a few chauffeurs. Riding as passengers were at least a dozen men whose names have a significance that is nation-wide.

Governor Hoke Smith of Georgia entertained Governor Woodrow Wilson of New Jersey as far as noon-control at Trenton and it is said that the Governor of Georgia remarked to the Governor of New Jersey on one occasion when it seemed as if there might be some lateness at noon-control: "Let's beat it."

There were big welcoming delegations at Newark, New Brunswick and Trenton. The column reached Philadelphia in perfect order and with no perceptible straggling.

Besides the contesting cars there were thirteen officials, non-contesting and press cars attached to the caravan. All told there were about 275 persons riding in the cars.

At Philadelphia the associated automobile clubs tendered the tourists a smoker and entertainment at the Hotel Walton which was liberally attended. The day's route was 101.1 miles, all of which was over excellent roads.

This is primarily a good roads tour. There are no technical penalties to be imposed, reliability in reaching controls on time being the single requisite for a clean score. The total mileage to Jacksonville is 1460.6 and the daily routes are not particularly strenuous.

The main trophy presented by Charles J. Glidden and which bears his name will be awarded to the three-car team that finishes the run with the least number of demerits. The Anderson S. C. trophy will go to the car having the best score and in addition cash prizes of $199 will be given to the runabouts and touring cars in each of the seven divisions of Class A under the rules of the A. A. A. In case of ties for either trophy the winners will be selected by drawing for numbers or flipping a penny.

Philadelphia to Gettysburg

Gettysburg, Pa., Oct. 15—To-day's penalties are: Chalmers No. 27, 13 points; Cadillacs Nos. 28 and 29, 4 and 15 points respectively; Halladays Nos. 34 and 36, 63 and 31 points respectively. Besides these Flanders 53 broke an axle and was not in at midnight.

Three teams lost their chances for a clean score as a result of to-day's run in the Glidden tour. One unattached car, Chalmers 27, was also penalized for lateness into night control. The sufferers were: Cadillac 28, which loafed along this morning and then had tire trouble while trying to make up time; Cadillac 29, which went astray from the confettied course and experienced tire trouble while racing to control; Halladay 34, which skidded into a curb while in control at Lancaster and bent its right front spindle and axle and smashed its running board; Halladay 36, which took its points for standing by its disabled teammate, and Flanders 53, which suffered a broken axle near Gettysburg and is still out at midnight.

Sunday dawned with leaden skies and at checking out time the rain commenced to fall dismally. All day it continued intermittently and despite the good roads traversed before reaching Lancaster, Pa., several of the cars were in trouble at noon control. The route was only 120.1 miles and was all good except about 8 miles into night control. These 8 miles, however, are notoriously the worst in Pennsylvania and they racked and strained the cars so that many of them will show the effects between this time and final control at Jacksonville.

A visit to the battlefield at Gettysburg was the feature of entertainment offered the tourists this afternoon and many of them took advantage of it. A canvass of the party disclosed the fact that almost without exception the tourists were represented in the great battle of 1863 by near relatives. As the party is composed largely of Southerners, the side that fought under the Stars and Bars received the more general scrutiny as to position on the battlefield. Governor Smith of Georgia entertained Governor Tener of Pennsylvania over part of the course to-day.

Out of the contesting column, which consists of eighteen teams and ten unattached cars, all have clean scores except the Albany, Ga., team, Florida State team, Detroit team and the Chalmers car as stated. The Maxwell, Marathon and Metz teams are being very carefully driven and have not suffered so far. The big cars have performed splendidly so far, Thomas, Packard and Pierce-Arrows going along without a skip and the Stevens team doing brilliant work. One noteworthy feature of the run has been the freedom from engine trouble, practically none of it having been encountered by the participants of the Glidden Tour up to this time.

Entering Dixie Land

STAUNTON, VA., Oct. 16—The only penalty to-day was E-M-F No. 42, which has not reported yet. To the inspiring strains of "Dixie," the Tour rolled into Staunton this afternoon after the longest run of the tour and what will certainly be one of the pleasantest. The dust and rain and fog disappeared at the entrance to the smiling Southland and the Virginia roads fulfilled all the pleasant promises that had been made for them.

Three of the greatest battlefields of the Civil War were traversed to-day when the cars passed over a part of the Gettysburg field, where the pivotal contest of the war was fought; Antietam, where the blue and gray battled to a desperate draw and the great Shenandoah Valley, where Early, Stewart, Sheridan and Warren battled to and fro and devastated it for three fierce years.

To-day there is no sign of that struggle in the peace and prosperity that enwraps the valley save that here and there the beloved Stars and Bars are displayed in honor of the tourists alongside the Stars and Stripes.

Winchester, seated at the gateway, is one of the best automobile towns of its size in the country. There are over 300 small cars of one make owned in Winchester and through a radius of ten miles. The city has five lively and prosperous agencies which handle a typical line of automobiles. Winchester is immortalized in heroic verse of Buchanan, describing Sheridan's wild ride to rally his disordered troops and gain a fundamental victory from what looked like disaster.

One of the features of the reception at Staunton was the parade of the cadet corps of the Virginia Military Institute. This battalion stood at Present Arms during the passage of the contest in cars.

There was only one penalization as the result of to-day's run. E-M-F 42 ran into a chuckhole near Charleston, W. Va., and wrecked two wheels. The car had not reported at 9 o'clock to-night and will receive a large number of demerits. It is being repaired as rapidly as possible.

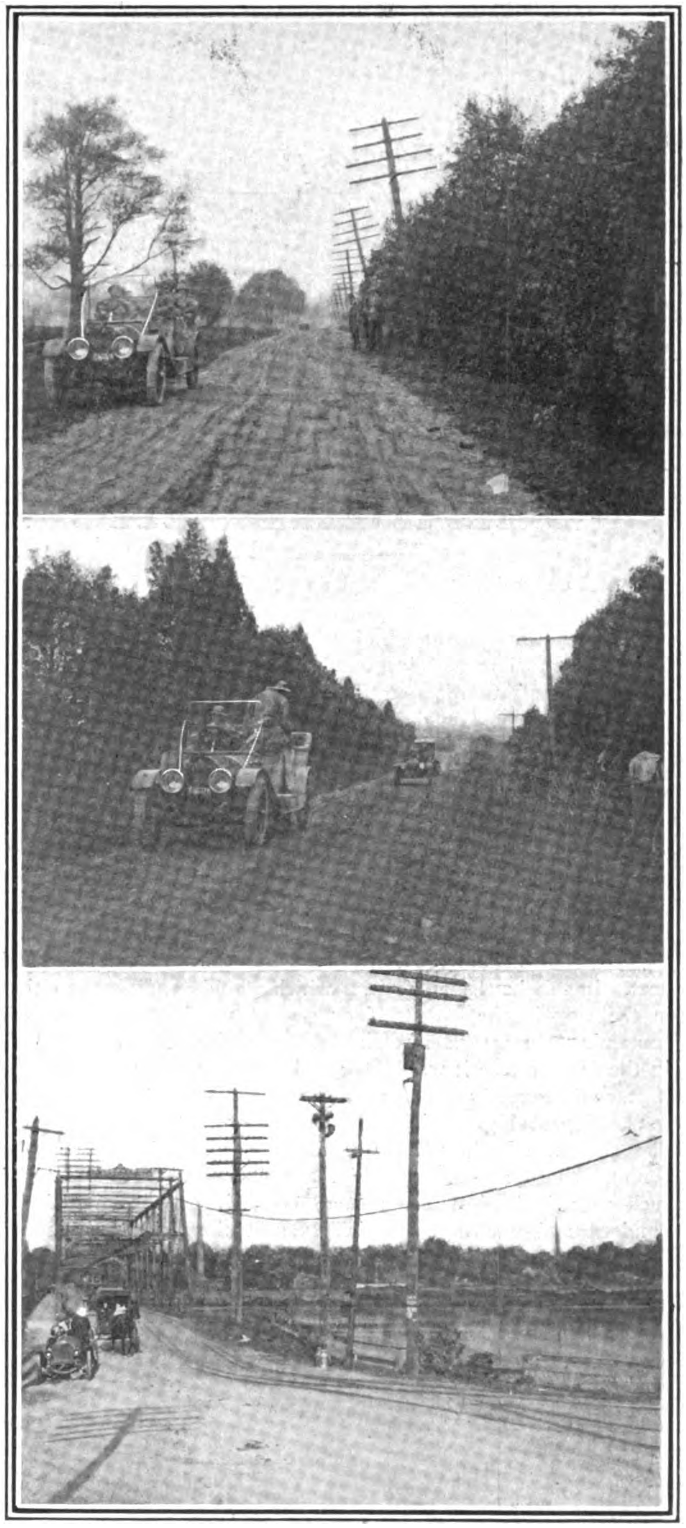
There was one accident during the run. The Pierce-Arrow press car carrying the starter and his assistant and driven by O. A. Brictson of Brookings, S. D., rammed a telegraph pole while going at a high rate of speed and turned turtle. Nobody was hurt but the car was badly damaged. The fault lay in the fact that too much speed was being used.

There were two additional penalizations for yesterday's run that were not included in yesterday's scores. These were Cadillac 74, which was given 3 points for being late after losing its way, and E-M-F 42, which was demerited 53 points after suffering a road accident in the heavy going east of Gettysburg. Flanders 53, which broke an axle on the second day, reached control at Gettysburg at 3 o'clock this morning, joined the column and made a perfect score to-day. Its penalty for lateness was 591 points.

There were no penalties posted to-night as the result of to-day's run.

Governor Smith entertained Governor Glasscock of West Virginia for part of the day's run and is booked to ride with the governors of all the States traversed by the tour.

Glidden Tour Road Scenes



These illustrations show typical road scenes on the route of the Glidden tour through the State of Pennsylvania. Both of the upper illustrations are photographic reproductions of roads in the vicinity of the famous Gettysburg battlefield, which point was reached on Sunday evening after travelling all day in a steady rain. The bottom illustration shows the bridge over the Delaware River on the boundary line between New Jersey and Pennsylvania; this point was passed on the first day of the tour. The roads on the first portions of the tour will be much better than those near the end of the tour in Southern Georgia and Florida.

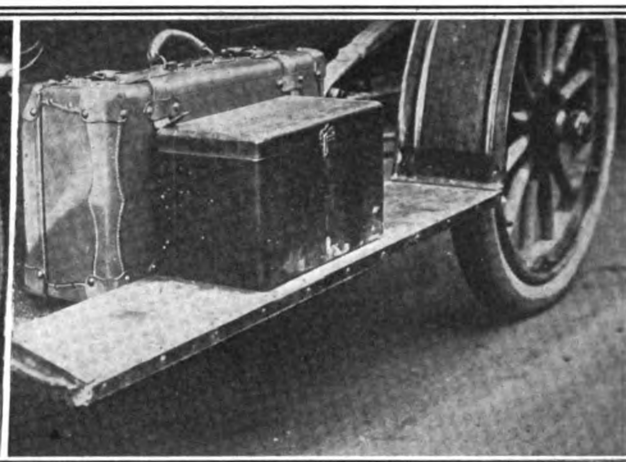

Fig. 2—A suit case can be placed between the running board and body

Subduing the Baggage Problem

THE cars which were lined up for the start of the Glidden tour could not but inspire a large amount of food for reflection in the mind of one who strolled along the length of the line and inspected the various methods adopted by the entrants to the tour in storing their baggage and spare parts. The inspection did not have to be more than casual to disclose the fact that while neatness was the predominant feature with a majority of the contestants, there were many whose baggage arrangements could have been markedly improved.

With very few exceptions, the running boards of the cars were called upon to play a significant part in the transportation of the dead weight. The arrangements were many and indicated wide variations in the ideas of security held by the owners of the different cars. In many cases an extra box was fitted alongside the toolbox and the appearance was very workmanlike and neat. In this box small articles which would generally be either in the way in the car itself or else at the bottom of a pack containing a mass of material of large size, could be packed. In the former case it would as a rule be thrown away in disgust if it could possibly be dispensed with, while in the latter case it would probably be dispensed with after a vain search and a like amount of disgust. With the small box fitted upon the running board as shown in Fig. 1, the little pieces of material such as a ball of twine, a small coil of wire or any of the hundred and one things which suggest themselves as needed upon a tour of any length, may be comfortably stowed away where they will be at hand whenever they are required.

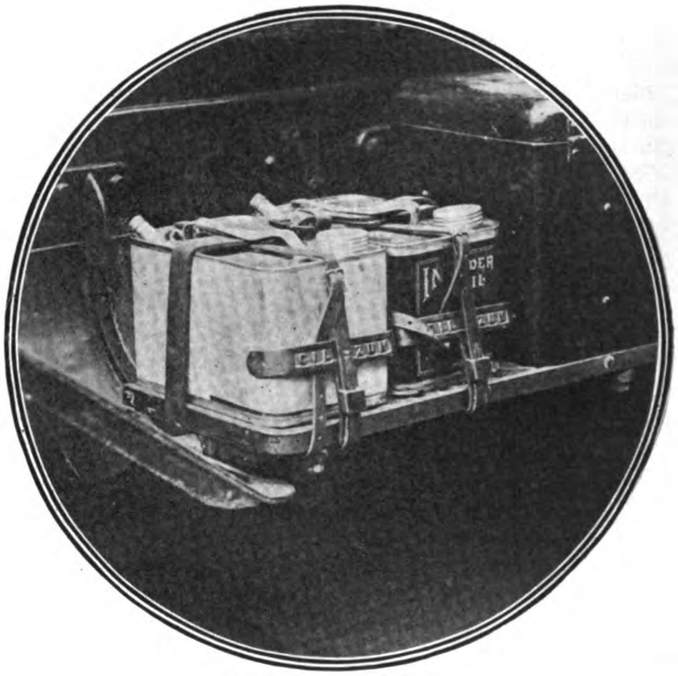

Fig. 3—Neat brackets with straps for carrying oil cans on running boards

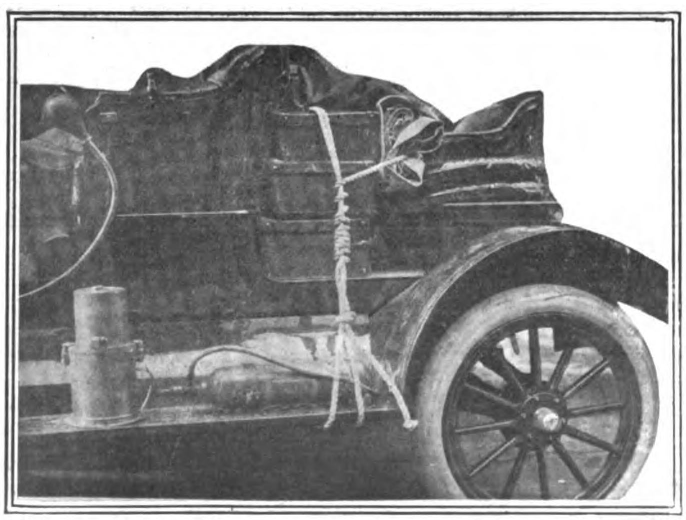

Fig. 4—This is not the neatest way of securing suitcases on a car during a tour. A strap would have been much better

In place of the small box a suit case will often be fitted as shown in Fig. 2. If this be suitably fastened so that it will not acquire the disagreeable habit of jumping off the running board every time the car meets an inequality in the road, it will no doubt serve the purpose as well as the small box mentioned above.

The running board can be utilized in other ways as is shown in Figs. 3 and 4. In the latter of these two illustrations the rear of the car is depicted laden with suit cases which seem to be fully capable as far as size and quantity are concerned to carry the needs of the two passengers for which the car is adopted upon a tour of remarkable length. A watertight cover can be seen stowed just to the rear of the suit cases. This is for use no doubt in case a rain storm should spring up. Since a storm is not governed by any laws of appearing gradually it is assumed that the cover may be taken out in a hurry; from the manner of roping down the suit cases and cover with one rope it would seem to indicate that after the storm cover were detached it would be necessary to rebind the cases. This is not convenient. A neat method of carrying oil cans is disclosed by a glance at Fig. 3. Bronze brackets are fitted which support the cans and pass beneath the running board; straps are then attached to the brackets and the whole outfit is firmly held and yet can be taken down for use in a remarkably short space of time. The tool box is fitted next to the oil cans so that the whole available space on the running board is made use of and yet it does not give a littered appearance.

The arrangements in the tonneau of the cars on a tour where passengers are carried are of great importance. This will no doubt be food for reminiscence for those who have ever had the questionable pleasure of traveling in a car for any length of time, when the tonneau was so crowded with excess baggage that the only apparent place to put their feet was somewhere in the neighborhood of the top of the front seat. It is a fact that the more one travels the less one carries. Every trip of any length will disclose the fact that some formerly treasured

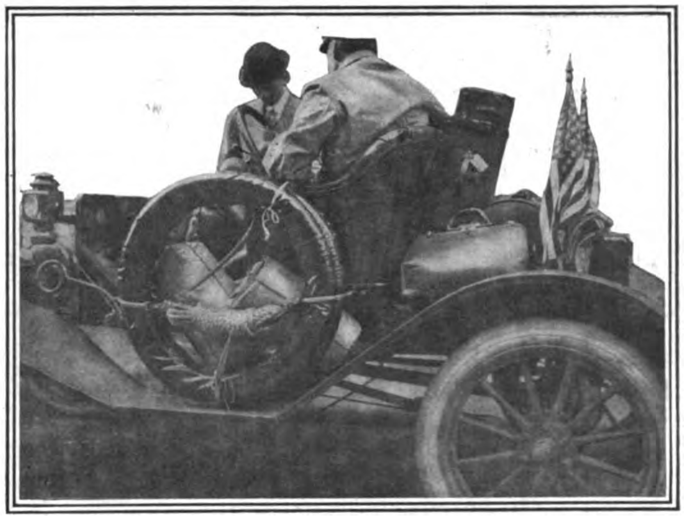

Fig. 5—The good appearance of any car is spoiled by cluttering it all up with baggage, at each side and in rear

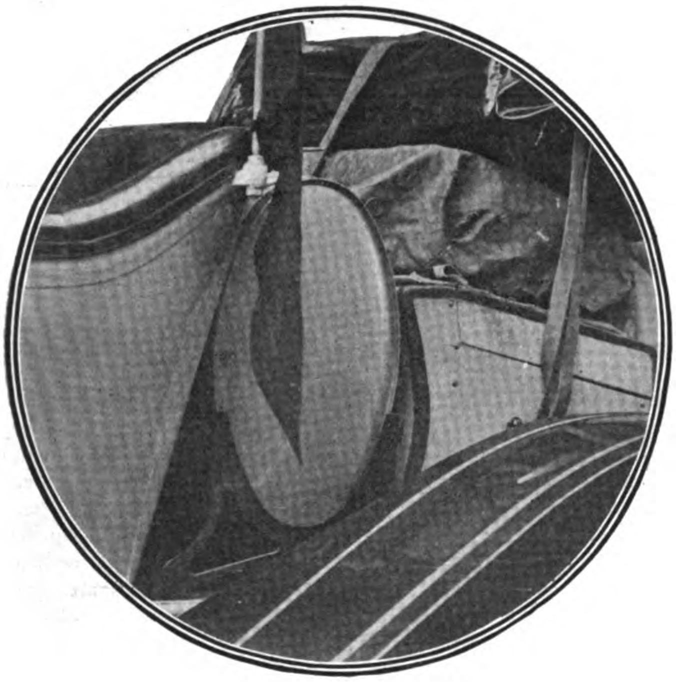

Fig. 6—Suit cases can be wrapped in waterproof cloth and carried back of the gasoline tank

piece of baggage could be dispensed with and its loss never felt. Yet it is none the less a fact that what many persons regard in the light of effete luxuries are to others indispensable necessities, yet even when carrying these few piecs of perhaps unnecessary luxuries, it is generally the case that they can be stored with a little care so that they will never be the cause of the slightest annoyance to the driver or his passengers. On the other hand a glance at Fig. 8 will show a case where the storage of loose articles about the floor of the tonneau will probably lead to great discomfort to the passengers on the first bit of rough road encountered, and yet it is probably a fact that every piece of loose material is of necessity. One can however well imagine the lively tattoo that the jack will beat upon the sides of the oilcans as soon as the roads deviate from the smoothness of the populated districts.

In a tour of the nature of the Glidden, space and trouble may be saved to a number of drivers and other occupants of the cars by having a non-contestant car accompany them for the sole purpose of carrying their extra baggage. The tonneau of this car can be heaped to the gunwales with suit cases and boxes and yet the chances of losing any of them are comparatively slight. There are no passengers to be carried in the car in this

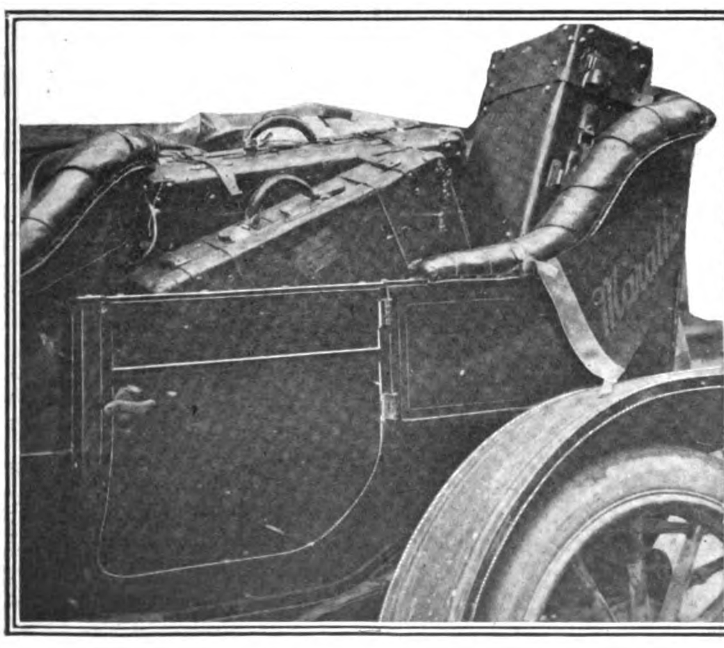

Fig. 7—This car was used solely to carry baggage for the tourists on the Glidden. There were some that carried baggage and passengers in the tonneau

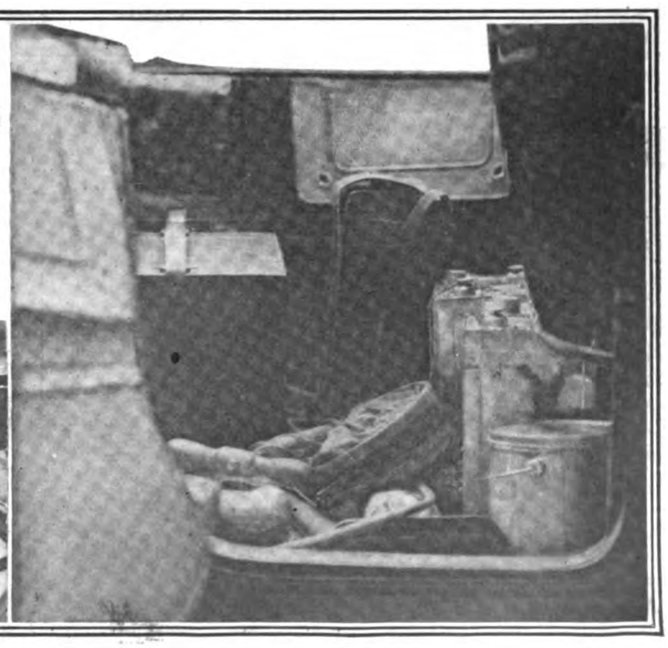

Fig. 8—This is the tonneau of one car that started on the Glidden tour. Baggage, gasoline, oil and tools were all mixed together

Fig. 9—A carful of ladies ready to start on the Glidden Tour. Note the poor position of the valise on the side compared to the valise on the rear

case and therefore there will be plenty of room as may be seen in Fig. 7, where the non-contestant car in the Glidden Tour is illustrated.

There is nothing, perhaps, which will tax the ingenuity of the tourist so much as the arrangement of the spare tire cases, and

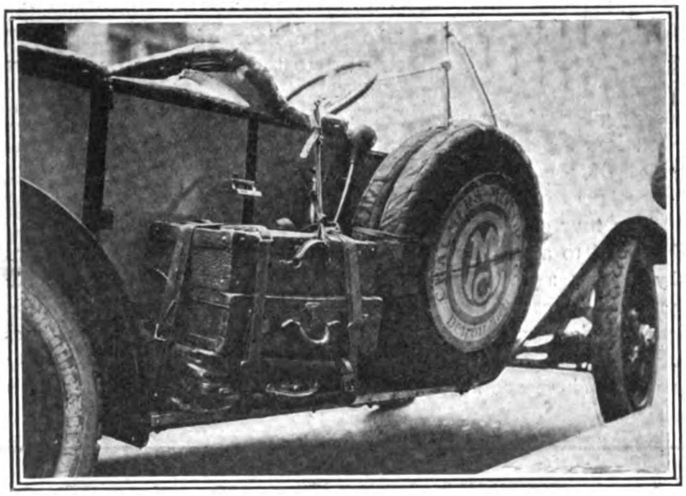

Fig. 10—Suit cases lend themselves to storage because they are flat

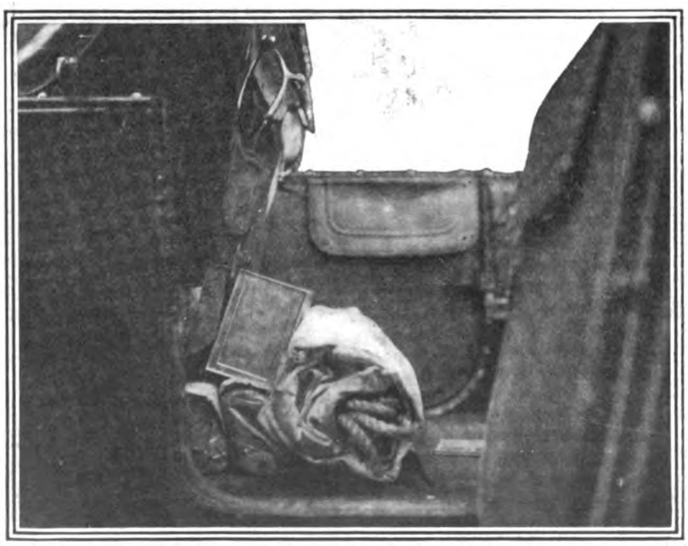

Fig. 11—Plenty of room for the passengers in this tonneau

in this matter it is as a rule better that some standard contrivance which has been made for the purpose, be used. It is needless to say that the tire should be well covered, for anyone knows that it is anything but a delectable occupation to scoop the accumulated mud and dirt from the interior of the shoe before fitting it to the rim. In most cases the tires are covered and there are few uncovered cases among a line of cars starting upon a lengthy tour; it was the case, however, in the Glidden that many pinned their faith to brown wrapping paper of rather uncertain thickness which may or may not be a wise proceeding, according as to how thoroughly the casing was bound up in the paper and how well the fastenings were made. A convenient method of carrying spare tires is illustrated in Fig. 5, where the tires are shown upon the running board helping to support two parcels. The coil of rope which should always accompany a car when on a tour of any length is bound to the spare shoes in such a manner that it may be readily detached in case of need.

The rear of the car forms the most natural point to suspend the baggage. A neat arrangement of cases will permit of a considerable amount of weight being carried in a manner that it will not take up an excess of space. A reference to Fig. 5 may be made for the purpose of pointing out the small valise stowed upon one side. A valise makes a very fine bag to carry in the hand, but its shape does not aid it in its amenability to storage. The suitcase, on the other hand, on account of its shape may be fitted nearly anywhere. It is evident to the observer that the valise in the illustration would be in grave danger of falling out upon the slightest provocation. An arrangement of suitcases in the rear of the car is shown in Fig. 12. There are three here piled one upon the other and when strapped as shown, are as safe as could be desired from any road shocks or other ordinary vicissitudes of automobile travel. Another case of three suitcases being piled upon each other may be seen in Fig. 10 where the running board is utilized for the purpose. There is plenty of baggage room here for three people and yet room for the spare tires is also found upon the same running board.

Next to the suitcase or the trunk, in order of amenability to storage comes the flat package. Examples of the manner of storing these packages may be seen in Figs. 6 and 15; these take the place of a trunk and are capable of carrying more than a single suitcase. They have the disadvantage, however, that the whole outfit has to be unpacked for the purpose of removing any one article no matter how small it may be. These tarpaulin packages have the same feature as the suitcases, however, inasmuch as they are capable of being stored nearly anywhere the driver may wish to put them. Only the larger cars are fitted with trunks as a rule, but a trunk rack is a handy adjunct to any car and where the owner has merely to let down the rack and place the trunk upon it he will be saved a large amount of trouble. An example of a trunk fitted to a touring car is shown in Fig. 12.

It is an impossibility for a car to make a successful tour without possessing the quality of being shipshape. Where all the luggage is permitted to float around the floor of the car loosely it is bound to cause trouble sooner or later. Everything should have a place and should be kept in it regardless of the fact that it may be of such a nature that it will be occasionally required by the occupants of the car. If it is of this nature, an arrangement such as a bracket may be made which will permit of easy removal and replacement.

Loose small articles should be studiously avoided. A heavy jack should never be placed loosely upon the floor where oilcans are resting, perhaps without being tied, as is seen in Fig. 8. Dirt should be avoided just as carefully, as it can cause damage at times. A case in point is the radiator which may be choked with the mud thrown from the wheels. To prevent this occurrence aprons should always be fitted where the going is rough and muddy. The aprons are shown in Fig. 13 and illustrate the attention which when accompanied by foresight, will greatly eliminate worry on the tour. If all these points are noted the passengers in the tonneau will not, when on a rough road, have to futilely chase the tire pump while the jack is gaily ramming a hole through the expensive thermos bottle.

There are certain rules concerning the storage of baggage which should be followed whether the car is a contestant in a tour or is merely starting for a day's run over some nearby roads. They may be summed up in brief: The smallest piece of baggage should be as accessible as the largest, *i.e.,* if it is desired to jack the car up and remove a tire it should not be necessary to request the ladies who are occupying the seat in the tonneau to step out into the soft mud which generally surrounds the car when tire troubles put in their appearance. Another point which might well be made is to have the baggage so arranged that it will not be necessary to hunt vainly about the several packages before the one containing the article sought for is located. Last, but not least, the baggage should never, under any circumstances short of complete demolition of the car, be allowed to shift with the inequalities of the road. No one would think much of the captain of a ship who allowed himself voluntarily to be caught with a shifting cargo in his vessel's hold.

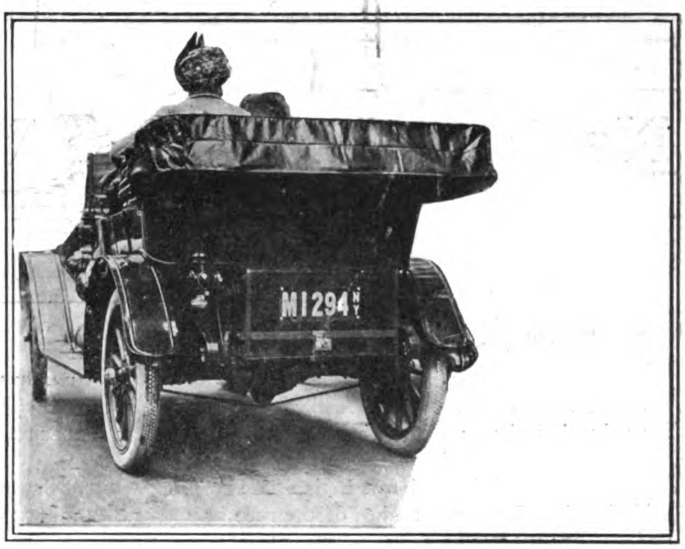

Fig. 12—There is nothing better than a neat trunk rack for carrying baggage

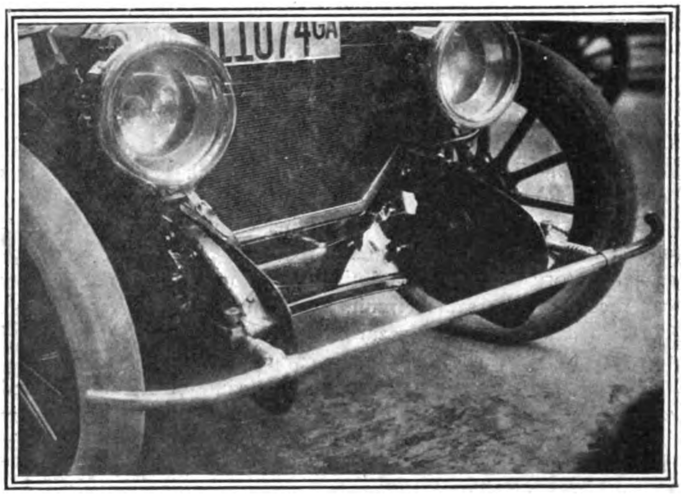

Fig. 13—Mud guards of this nature keep the radiator clean on long tours

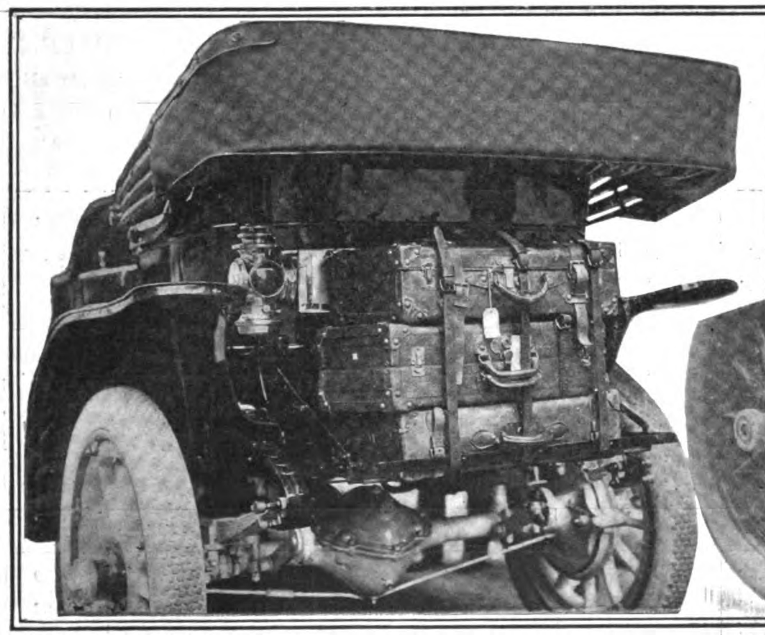

Fig. 14—Three trunks can be carried quite easily on a trunk rack on the rear of a car. They should be wrapped in a waterproof covering

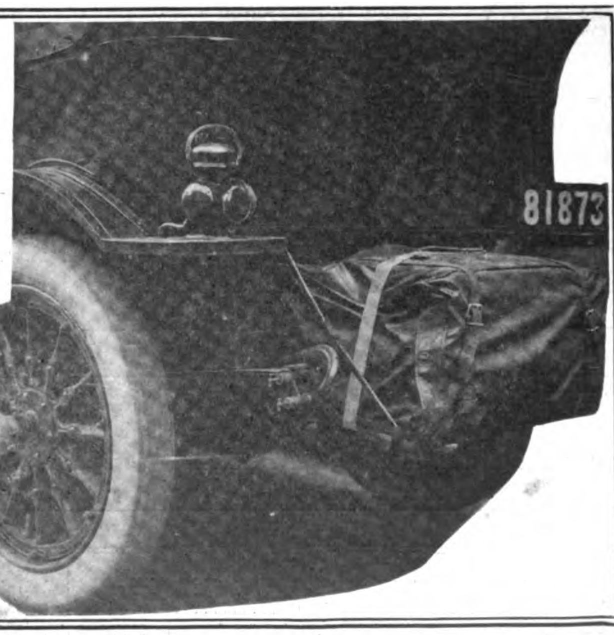

Fig. 15—If suit cases have to be carried on the back of a car, it is best to wrap them up to protect them from the rain and dust during tour

National Breaks World's Road Mark

Herrick and Merz Shatter Florio Mark

LOS ANGELES, CAL., Oct. 14—Special Telegram—America has captured the road race record of the world. Herrick, driving a National, broke it to-day on the now famous Santa Monica course near this city. Nazzaro, in the Fiat, has held the road race record since the season of 1908, but now it rests in America, an American car, driven by an American driver, doing the work.

Harvey Herrick is the hero; he is a Los Angeles boy and drove a National 40 for the 202 miles of the race in 2 hours, 42 minutes and 24.6 seconds, which is an average speed of 74.62 miles per hour. The previous road record held by Nazzaro was a speed of 74.3 miles per hour made on the Florio cup course in the season of 1908. The new figure of Herrick was made on a shorter circuit than that on which Nazzaro gained his laurels. Many attempts have been made to wrest the road record of the world from Europe, special roads have been built in different parts of America for this work, turns have been banked and other precautions taken, but the honor has finally been taken by the West, and Harvey Herrick, the hero, has been driving in West Coast events for the past six months. This record was made in the free-for-all race, the tabulation of which is given on this and the following page.

But Herrick did not have it all his own way in the record-smashing program on the course to-day. Charles Merz, a National factory driver, also piloting a National 40, won the heavy car race over the same circuit, averaging 74.42 miles per hour. He also shattered the Nazzaro figures, but was a little behind the pace of Herrick. This heavy car race was for 152 miles.

There were two other races over the same circuit to-day and also two winners. Keen, driving a Marmon in the 231-300 cubic inch piston displacement class, won, driving the 151 miles in 132 minutes and 9 seconds, which is an average speed of 68.7 miles per hour.

The last and smallest race of the day was for cars with a piston displacement of under 231 cubic inches and for a distance of 101 miles. Nikrent, driving a Buick, captured this event, doing the distance in 103 minutes and 21.70 seconds, which is an average of 59.20 miles per hour.

Herrick was the dark horse in the big race. He had to his credit the Bakersfield road race of last July and the Los Angeles to Phoenix desert race of last year. But he was not even a member of the National team which came out from the factory. In deference to the local agent, Herrick had been permitted to handle the car which was already here. When the coastman finished last with the same car in the 301-450 class event he became even more of a dark horse. His trouble in the heavy car event had been due to tires. He was making too much speed around corners. In the time between the class race and the free-for-all Herrick quietly mapped out his race and once under way he furnished the most consistent performance ever seen in an American road race.

The free-for-all for the Dick Ferris cup was a bitter fight between the Nationals and the Marmons. Bert Dingley in a Pope-Hartford was a contender up to the twenty-second lap when repeated tire changes put him out of the running. The fastest laps were reeled off by Tetzlaff, the winner of last year's race, in a Fiat. With 75 miles of the race completed the Fiat led by 4 minutes but from there on it began having engine trouble. Several times Tetzlaff stopped and made minor adjustments on his engine and once changed spark plugs at his pit. During the last half of the race he was not a contender.

At the start Tetzlaff and Wilcox in the National 50 set a hot pace. With three laps completed the Fiat led Wilcox by 56 seconds with Dingley third. The leaders had tire trouble in the fourth, but Tetzlaff retained his lead, while Patschke in a Marmon moved up to second and Dingley kept third. The Midland twisted its magneto shaft and stopped at its pit the first time around. Wilcox threw a tire on the Palisades turn, making a very spectacular skid, but bringing his car to a stop without trouble.

The only accident of the race occurred on the Interstate's fourth lap. Harry Endicott was approaching the turn when Tetzlaff overtook him and as they went into death curve together the exhaust from the Fiat blinded Endicott and he failed to make the turn, his car hitting the heavy iron rails which had been placed to prevent the cars crashing through a high board fence. The car was partially wrecked but with the exception of a few bruises and a sprained arm Endicott was not injured.

The first 50 miles was covered by Tetzlaff in 37:52. The Fiat had been reeling off laps at an 80-mile-an-hour average. The remainder of the cars were bunched, Patschke being 11 seconds ahead of Dingley, and Herrick 2 seconds behind the Pope-Hartford, and 1 second ahead of Merz. At the end of the ninth lap it was Tetzlaff. He led Patschke by 3 minutes 59 seconds. Herrick was 7 seconds behind and running strong. Tetzlaff came to grief on the tenth lap. He tried to take the Nevada turn too fast and blew two tires. This lost him the lead, Patschke taking first, followed by Herrick only 11 seconds behind. Even this far the ultimate winner was being given little consideration. This condition continued through the next lap, Dawson moving up to third. Wilcox had been gradually losing out on account of tire trouble. He changed two tires in the eighth lap and also stopped in the thirteenth, fifteenth and twenty-first.

It was Patschke, Herrick and Dawson in the thirteenth and in the fourteenth Herrick gained 3 seconds on the leader. A tire change threw Herrick back into fourth place in the fifteenth, Dawson going to second and Dingley to third. Tetzlaff was 14 minutes behind, completely out of it. Dingley crept up to second in the sixteenth and was still holding that position the next time around. Two bad laps sent Dawson back to fourth, Herrick coming to third.

With four laps yet to go, Patschke was leading Dingley by 1:05. Herrick had been making up his lost seconds and was only 7 seconds behind Dingley. At this stage it was anybody's race. One more lap and Herrick had taken second place from the Pope-Hartford, but the Marmon still led. The Marmon went by the stand missing and from there on Herrick went after the race, making his fastest laps toward the end. The twenty-third lap put Dingley out of it and from there on it was easily Herrick. With only 16 miles to go the result was still in doubt and the winning by the Los Angeles boy was the cause of the wildest enthusiasm.

Patschke and Dawson rolled into second and third places when Dingley fell by the wayside. Merz in the second National 40 had been coming fast and finished fourth.

The heavy-car race, for the Leon Shettler cup, was a battle royal between the Pope-Hartford, Stutz and two Nationals. Dingley was away in front and he continued to hold the advantage until the eighth lap. Tire trouble stopped Herrick in the fourth and fifth laps and Dingley made a change in the eighth. The tenth lap once more saw Dingley leading with Merz 6 seconds behind and Lewis in the Stutz and Herrick less than a minute in the rear. The eleventh brought more grief to Herrick in the shape of bad tires, while Merz continued to trail Dingley by 5 seconds. Merz gained a second on the next round and on the fourteenth, when Dingley was twice forced to stop for tires, the National went to the front and was never headed. At the finish only 2:56 separated the first and fourth cars.

The medium-car class was a hot fight between the Marmons, Mercer and Buick. At the finish of the fifth lap Keen in a Marmon led Nikrent, also in a Marmon, by 23 seconds. With ten completed Keen led by 59 seconds with Hanshue in the Mercer 34 seconds behind. Nikrent with only 3 laps to go was 48 seconds behind the leader. Keen won by 53 1-2 seconds over Nikrent and 1 1-2 minutes ahead of Hanshue. Nine started. This race was run at the same time as the heavy-car event.

Nine started in the light-car race, for the Chanslor and Lyon trophy, at 101 miles, which was sandwiched in before the free-for-all. The Maxwell lost its flywheel in the third lap and the Regal had engine trouble. Hanshue, in the Reo, set a fast pace but by consistent running Nikrent took the Buick to the front in the latter part of the race. The E-M-F looked all over the winner as late as the ninth lap, but a broken water connection caused a stop for repairs and more water and this lost the race for the Detroit car. The Ford was second to the Buick.

The day was ideal for racing, the warmth of the California sun combining with the breezes of the Pacific to make a balmy Spring day in October. Racing started at 8:30 and there was only a short intermission between events.

The crowd was immense, being estimated all the way from 75,000 to 100,000. It formed a solid mass of people around the entire 8.4-mile circuit, and every available seat was occupied. With the exception of the slight accident to Endicott, not a person was injured. The course was well guarded and the people gave the cars all the track. Several of the drivers provided thrills at the turns, a number going straight ahead at Nevada. This turn was banked last year. This year it was left flat and despite the fact that it was a right-angle curve all cars but one took it without accident.

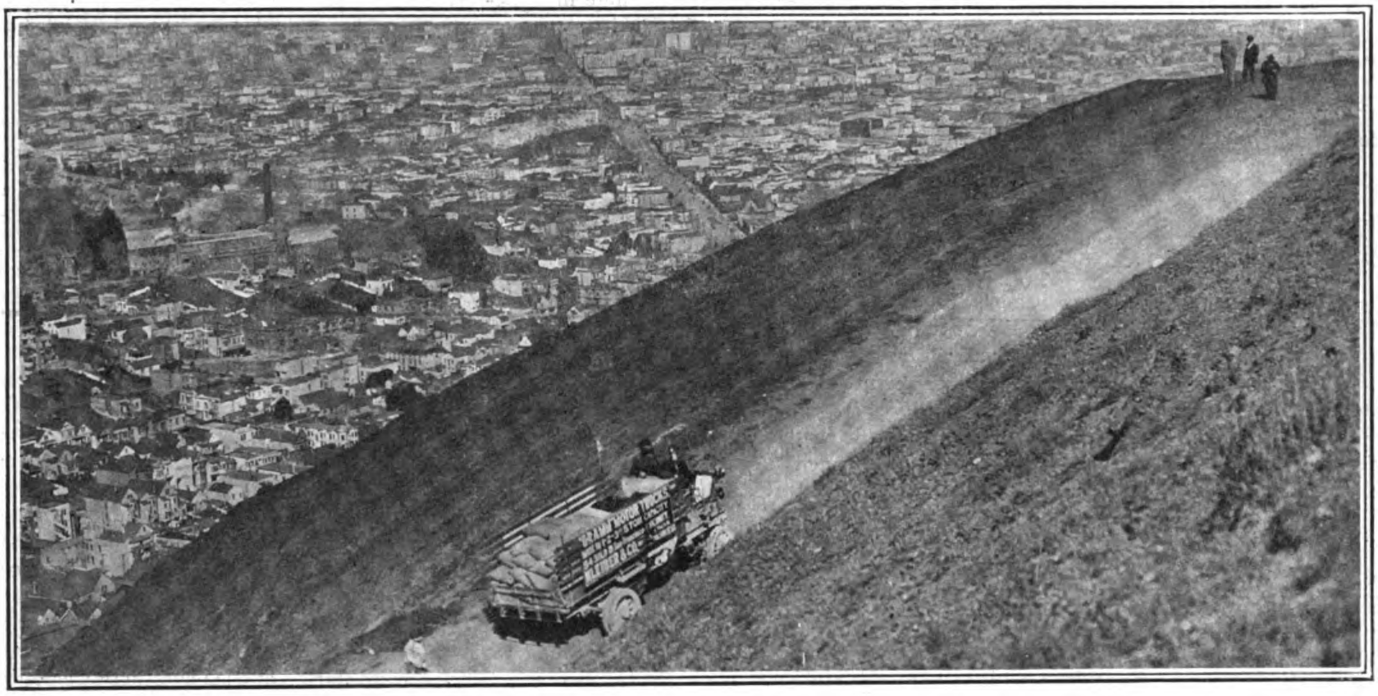
California Tests Commercial Cars



Gramm 6-ton truck, which finished with a perfect score, climbing Twin Peaks Hill

The Speedwell truck, which went through the run without a penalty

SAN FRANCISCO, CAL., Oct. 7.—California set the ball rolling in the commercial vehicle test held on October 4 and 5, when twenty-two trucks and delivery wagons contested over roads and city streets. When the 2-day test was over eleven still had their perfect scores remaining, a most creditable performance for a test of the kind. The winners in the six divisions were:

Division 1K, up to 500 pounds—Brush delivery car.
Division 3K, 1001 to 1500 pounds—Reo light delivery car.
Division 4K, 1501 to 2000 pounds—Grabowsky truck.
Division 5K, 2001 to 3000 pounds—White No. 4.
Division 8K, 5001 to 7000 pounds—Kelly truck.
Division 9K, 7001 to 10,000 pounds—White No. 19 and White No. 23 tied.

These awards were made on the basis of road and technical scores and the economy record according to the rules of the American Automobile Association. In addition to these winners perfect scores were made by the Pierce-Arrow and Speedwell in the ninth division; the Packard and Gramm in the eighth division; the Autocar in the fifth division, the Buick and White No. 1 in the third division; and in division No. 1 by an Indian motorcycle delivery van.

The test was a 2-day affair, the first day being on the road and the second day about the streets and the hills of San Francisco. On Wednesday the twenty-two machines started from this city, crossed the bay by ferry, and made a run of 50 miles to San Jose. An hour was taken out here for luncheon and the cars then returned up the peninsula to San Francisco—the entire distance for the day being a little less than 100 miles.

Thirteen of the twenty-two cars came through this test, carrying their full capacity loads and some of them an over-load, with perfect scores.

The Franklin 1-ton truck lost its perfect score by dropping a pin out of the toggle joint. The missing pin was replaced with a twenty-penny nail and the car got along perfectly with this contrivance for the rest of the 2-days' test. In the fourth division the Grabowsky developed a leak in the gas tank. The Federal in the fifth division lost 25 minutes as the result of a broken steering arm. In the eighth division the 3-ton White No. 9 lost the water from its radiator. The motor heated and 15 minutes were lost in the search for more water. The Reliance burned a brake and had trouble with water in the carbureter. The Pope-Hartford broke its gasoline pipe line on its way to San Jose and lost 30 minutes. The Kelly dropped its pan. The Universal had motor trouble and was subsequently withdrawn. In the ninth division four of the five cars made perfect scores The unlucky one was the Lewis, a home production, which broke a radiator spring.

At the top of the hill the cars were put through a clutch test. A platform had been built with an 8-inch curbing at one end. Each truck was compelled to place its front wheels against this and either climb it, spin its rear wheels or stall its engine. Every one of the cars succeeded in doing one of these things—proving

TABLE SHOWING ECONOMY RECORD IN TWO-DAY TEST

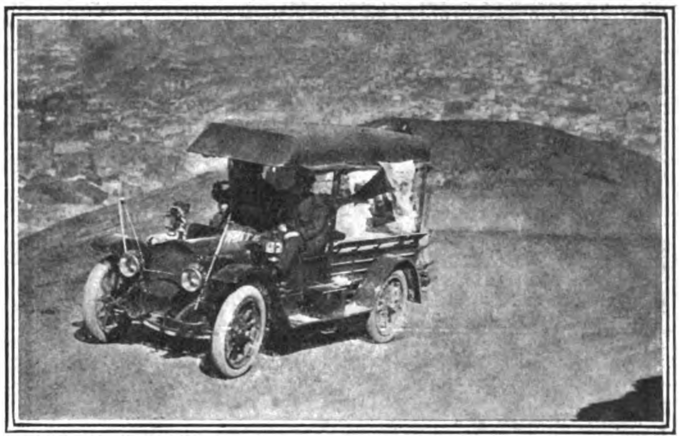
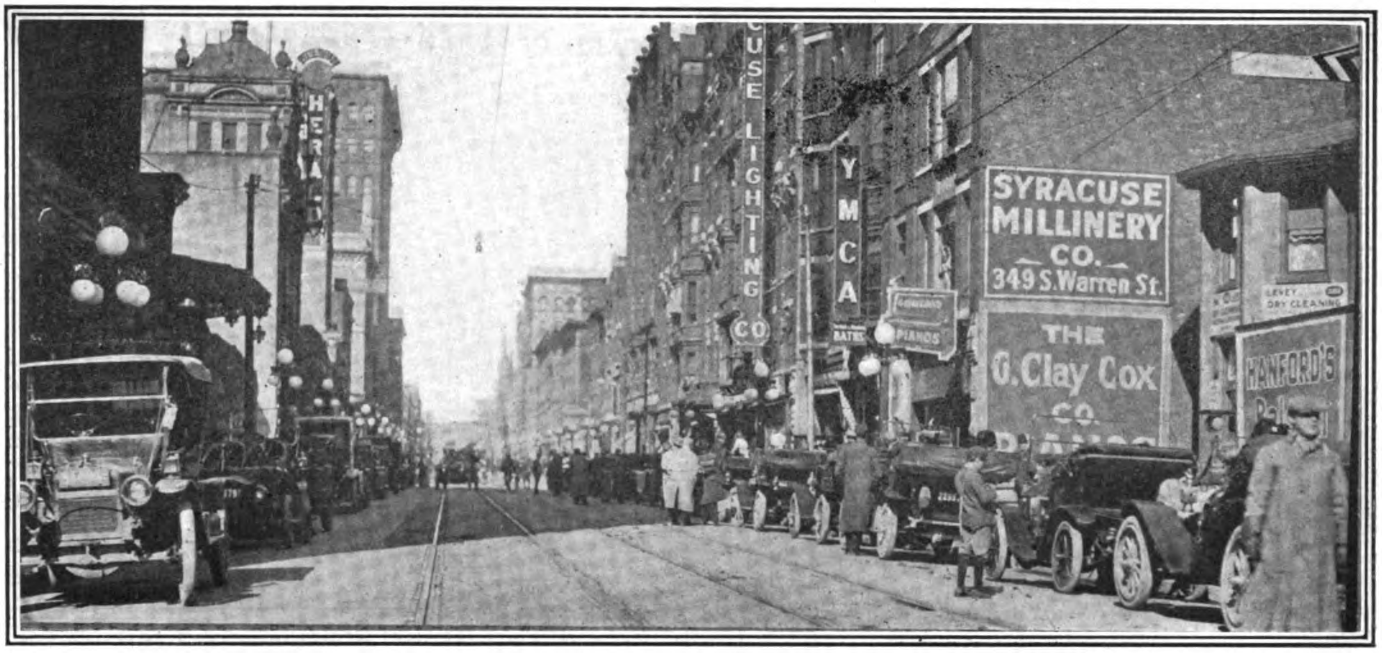
the efficiency of their clutches. The cars were then put through a brake test on an asphalt street. The Grabowsky failed to stop within the 50-foot limit on its emergency brake, requiring 68 feet to stop. The Reo also failed on both service and emergency brakes and the Brush's emergency refused to work under 134 feet.

The purpose of the second day's events, which were held entirely in San Francisco, was to draw the attention of the San Francisco business men to the possibilities and capabilities of the motor truck. During the morning the trucks were driven over some of the worst roads in the business and residence parts of the city—the route being chosen with the view to giving the cars a test over the bad streets and hills and through some sand. Every one of them came through this part of the day's events with a perfect score—much to the delight of the truckmen. San Francisco is a hilly city and it has always been held against the motor truck that this was an obstacle to its wide use here. The

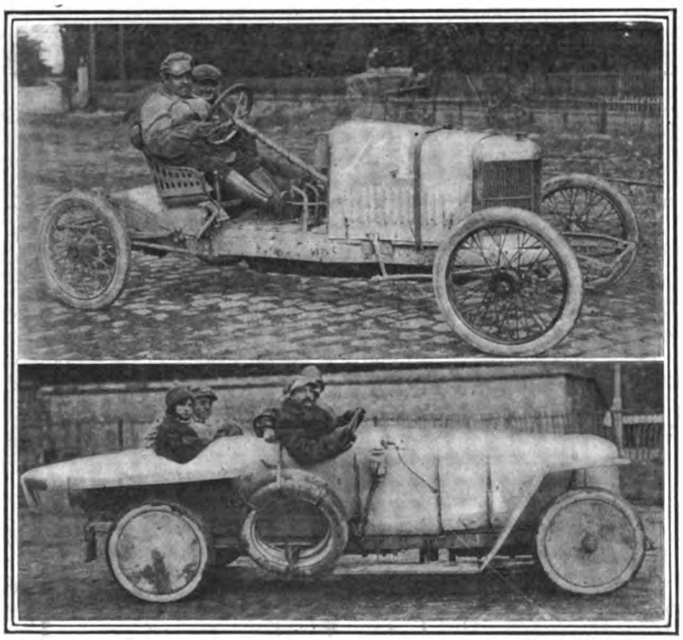


The five White trucks entered in the run made a good showing

Where the trucks checked in at one time during the two-day run



Start of the Syracuse *Herald* Sociability Run, in which fifty-five cars participated



Alcyon and Benz in Gaillon Hill-Climb

score made by the trucks on this day conclusively disproved the claim that they were not able to negotiate the hills.

In the afternoon the cars were given a supreme test in hill climbing. At the end of Market street, the main artery of the city's traffic, there is a mountain which goes by the title of Twin Peaks. There is a pretty good winding road all the way to the top and over this the cars were sent. It is a steady grade all the way without a let-up and in two or three places there are inclines that are unusually heavy. At the top of the worst of these grades the cars were compelled to make a turn so sharp that they almost doubled back upon their tracks. They did all that was asked of them, grinding steadily up the hill under their enormous loads, some of them moving along at a lively clip, others moving along more slowly but unfalteringly.

Hundreds of people had gathered along the route to witness the big machines as they made their way up and they saw every one of the cars carry without protest loads that could not have been taken up by horses except with great difficulty.

Gaillon Hill-Climb

PARIS, Oct. 5—The French classic hill-climb, the Gaillon climb, took place on Sunday and seventy-five cars were entered. The event is over a kilometer course on the Sainte Barbe hill, and when the times are taken into consideration it must be remembered that a flying start is allowed.

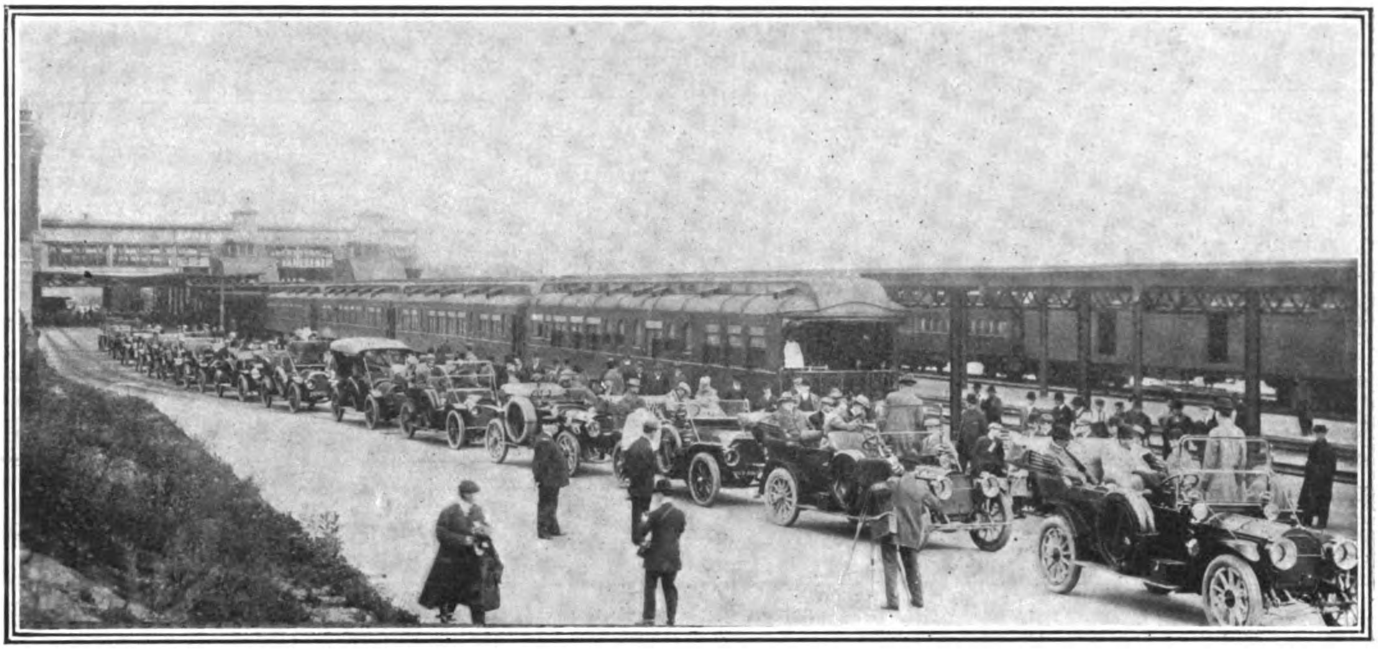
The record for the hill made last year, of 23 seconds, which approximates 95 miles per hour, was not beaten and the fastest time was made by Gaste on a Rossel six-cylinder car in 32 4-5 seconds. Second in general classification was a Mors racer of 1908, which ascended the hill in 36 1-5 seconds. Third place was taken by an Alcyon driven by Barriaux, whose time was 39 1-5 seconds.

One of the cars which competed and climbed the hill in 40 4-5 seconds was a Laurin-Klement car made in Austria, with a four-cylinder motor, 3 3-5-inch bore and 10-inch stroke. It was the longest stroke car in the climb.

In addition to the speed classification the cars were subdivided into classes and awards were made for efficiency according to a formula which took the weight of the car loaded, the sped, the gradient, bore and stroke of the motor and the number of cylinders into consideration, a constant being also used, which varied according to the class of the car. Class 1 was for racing cars and class 2 for touring cars. Under the formula classification the former was won by a Lion-Peugeot driven by Goux and the latter by a Hispano-Suiza driven by Pilleverdier.

Virginia Sociability Run

RICHMOND, VA., Oct. 14.—In a recent sociability run from Newport News, Richmond, eighteen members of the Peninsula Automobile Club motored from Warwick Hotel in Newport News to the Jefferson Hotel in this city, the average time for the 87 miles being 4 hours and 35 minutes. The first prize was awarded to H. J. Lenz, of Newport News; second M. C. Armstrong, of Hampton; third to C. T. Weaver, of Newport News. The run was not for the purpose of attaining a high speed, but the winners were determined by the three who came closest in their time to a figure selected secretly by a committee before the autoists started. The run was staged to stimulate local interest and it was very successful in this respect. It brought out a great many amateur drivers, who could not be induced to enter a severe contest.



President Taft after his arrival at Tacoma, Wash., started for Mount Tacoma. President is in second car

Syracuse Run a Success

Syracuse, N. Y., Oct. 14—The annual Syracuse *Herald* Sociability run, held yesterday, was the most successful held since the event was inaugurated 4 years ago. Fifty-five machines participated in a 60-mile run through a picturesque, rolling country southwest of this city, the cars being gaily decked. The run had to be postponed a couple of times because of rain storms, and the continued interest of motorists attested the popularity of the event.

Tradition was put to rout in that car No. 13, an Overland, containing Percival C. Shaw and Mrs. Shaw, came nearest the secret time of 3 hours 35 minutes and 16 seconds, and won possession for a year of the *Herald* trophy cup. Mr. Shaw's time was 3 hours and 30 minutes. He won a solid gold medal.

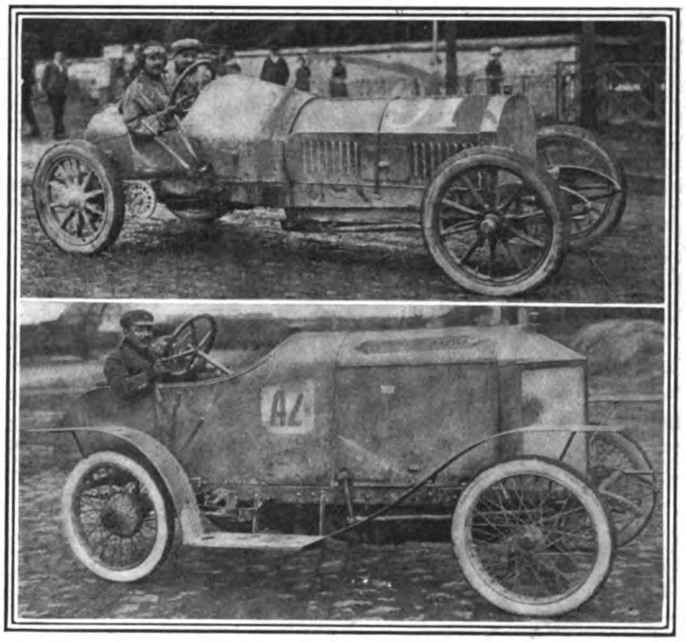
The second prize, which was a loving cup from the *Herald* Company, was won by Carl Ackerman with a Flanders; the third prize, a gold medal. was won by Dr. G. N. Hemmer with a Ford; and the fourth prize, a silver medal, was taken by E. R. Harriman with a Cadillac. Miss Florence MacDonald, with a Lozier, won the first women's prize, a cup from the Automobile Club of Syracuse. Miss Mabel Walliser, with an E-M-F, was second, and Miss Jessie Greis, with a Buick, was third. They received medals. The weather was ideal and the run was enjoyed by all the participants.

Abolish Park Racing?

Philadelphia, Oct. 14—A bombshell was thrown into the Fairmount Park Commissioners at their meeting a couple of days after the running of the Fairmount Park race, when Dr. J. William White, of the University of Pennsylvania, submitted a resolution suggesting the abolishing of the Fairmount Park road race. The resolution read as follows:

"Resolved, That in the opinion of the Fairmount Park Commission, it is inadvisable to continue the automobile races in the park in future years, and that to avoid disappointment and misunderstanding this opinion be transmitted to the persons chiefly concerned, and to make the same public."

No action has as yet been taken, and public opinion may be depended upon to do the rest. Just why the ban should be placed on these yearly events is not clear; four of them have so far been held without accident, providing an afternoon of enjoyment and keen interest to hundreds of thousands who have come to look on the race as an annual fixture.



Laurin & Klement in Gaillon climb

The winning Benz car has been on exhibition in the sporting department of Wanamaker's the past week, constantly surrounded by enthusiasts and the curious.

Detroit Conducts Sociability Run

Detroit, Mich., Oct. 14—Twenty-one entrants contested in the under-sealed-orders sociability run of the Wolverine Automobile Club, Sunday. It was a perfect day and many of the participants took their families along. The first section of the run was from Detroit to Plymouth, 30.8 miles; the second from Plymouth to Pontiac, 40.1 miles; and the final stretch from Pontiac to Detroit, via Utica, 40.1 miles. The going was excellent with the exception of about 3 miles. C. C. Cross, of the Chalmers Motor Company, won the silver trophy offered by the Home Telephone Company, his time being just 30 minutes slower than that of the pathfinder, which was 6 hours and 45 minutes. W. F. Wilson finished second and H. J. Porter, president of the Wolverine Automobile Club, third.

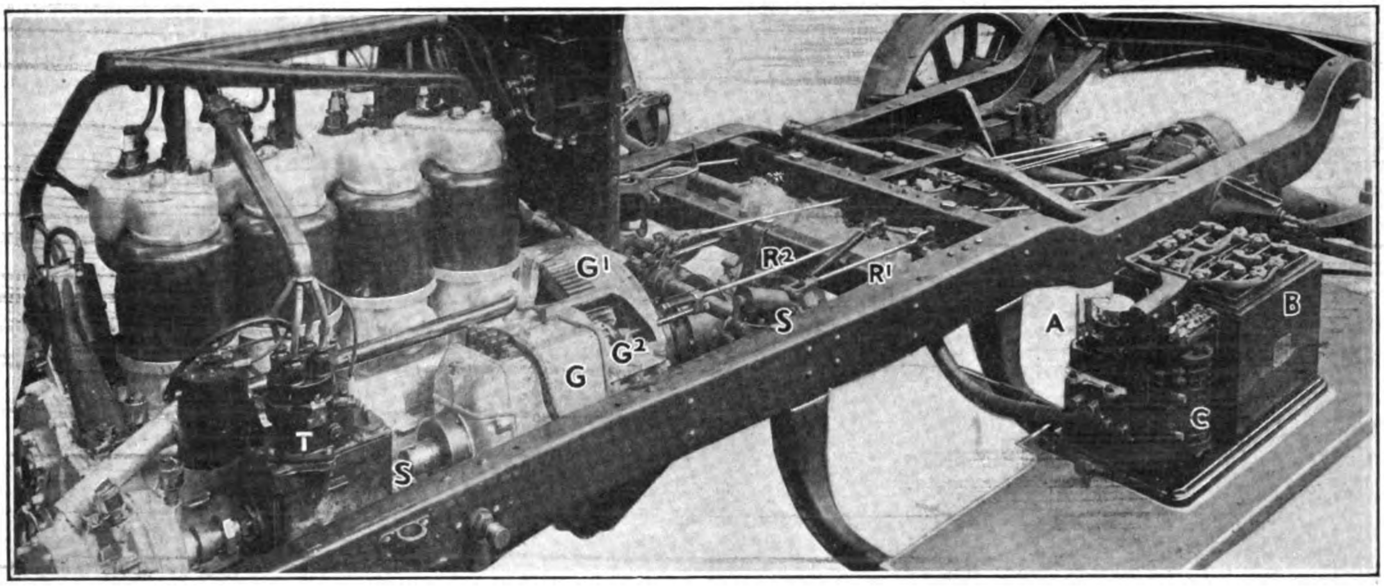


Fig. 1—Comprehensive view of the left side of the motor and the various parts comprising the self-starting device

1912 Cadillac Characteristics

THE new model of the Cadillac car, manufactured in Detroit, Mich., has not undergone any material alteration. Such refinements as have been deemed advisable in the light of a year's experience have been incorporated in order to render the product more efficient, but the outstanding feature of the 1912 model lies in the new self-starter effected by means of an electric motor which is capable of running both as a generator and as a motor. While running as a motor it starts the engine and afterwards furnishes current for one of the ignition systems and lights the lamps while the engine is running. The carbureter adopted for the new model has received careful study at the hands of the engineering and testing staff of the company and it is claimed that with this and the increase in the size of the motor bore the engine is considerably more powerful.

The size of the wheels has been increased as well as the diameter of the brake drums. The magneto has been eliminated and the second speed gear ratio slightly raised.

The outstanding feature of the Cadillac motor lies in the method of casting the cylinders. It is constructed on the built-up or individual unit principle. The section through the motor seen in Fig. 4 shows that the cylinder C proper is cast by itself as is also the cylinder head H, which contains the valves. The head is attached to the cylinder by means of the threaded nipple N. The water jackets C1 which surround the cylinders

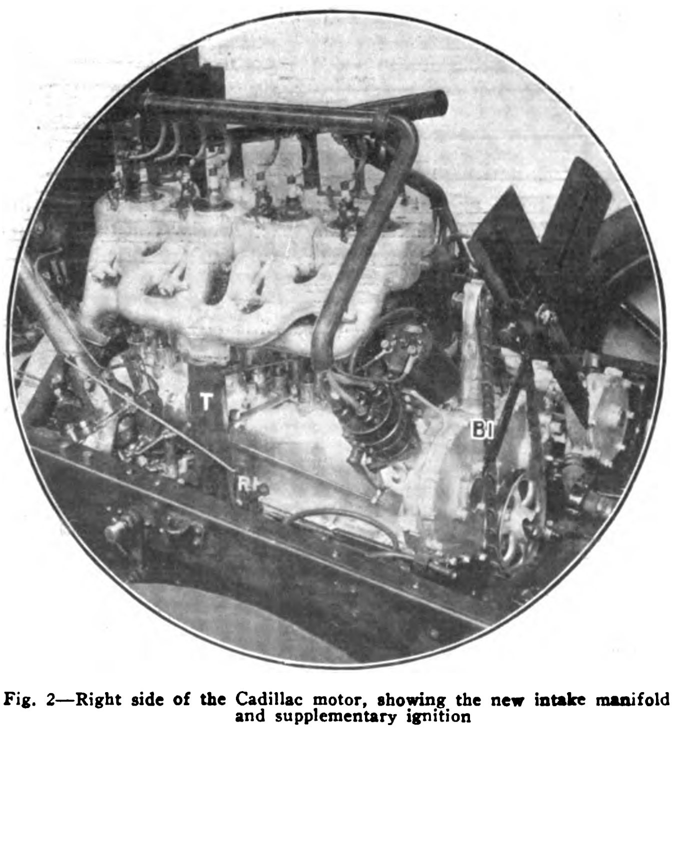

Fig. 2—Right side of the Cadillac motor, showing the new intake manifold and supplementary ignition

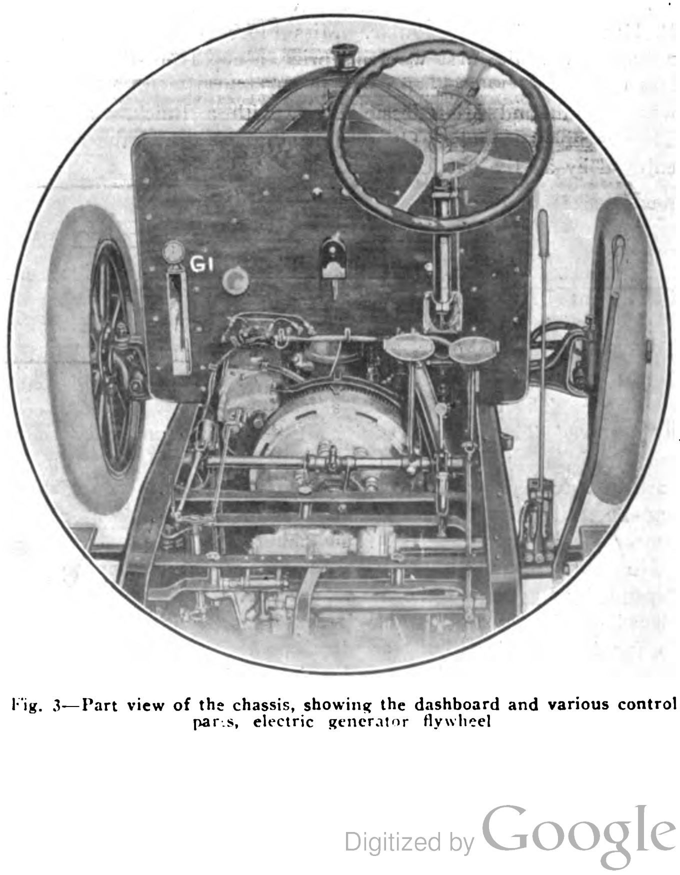

Fig. 3—Part view of the chassis, showing the dashboard and various control parts, electric generator flywheel

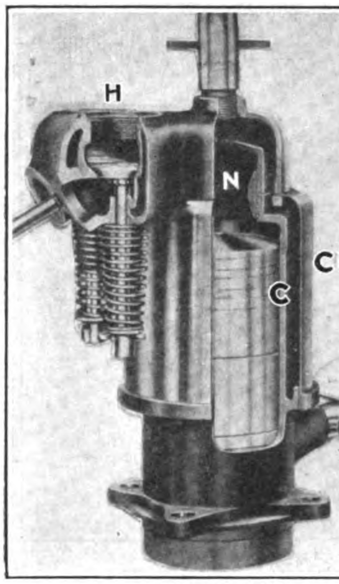

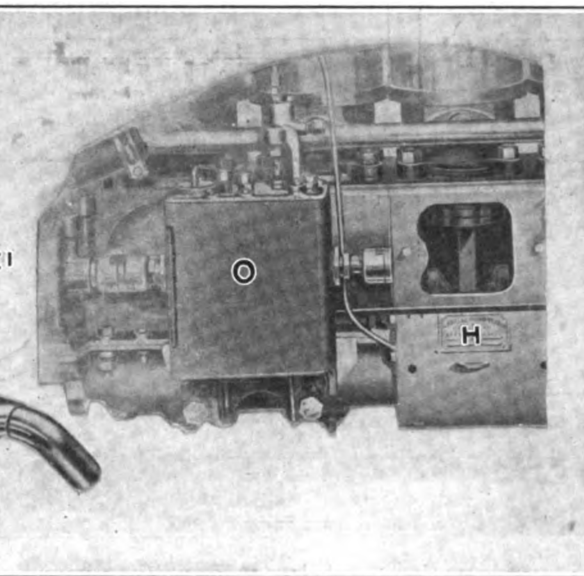

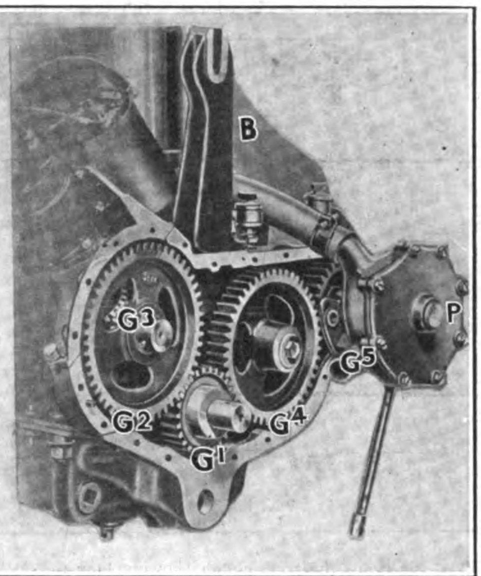

Fig. 4—One of the Cadillac cylinders with part removed

Fig. 5—Showing the oiler and hand hole in base-chamber

Fig. 6—View of the timing gears with the cover removed

are of spun copper and are clamped into position in the manner shown.

The bore of the motor has been increased from 4 to 4 1-2 inches, thereby making the motor what is termed square, the stroke of the piston being 4 1-2 inches also. The size of the valves has been increased in proportion to the bore and they are now 2 inches in diameter. A pointer is attached to the rear of the motor and together with it and the marks on the flywheel the correct setting of the valves and the ignition can be determined.

The valves are all placed on the right side of the motor, as can be seen by referring to Fig. 2, the push rods being fitted with adjustments to take up any wear from time to time.

The cylinders are first machined and afterwards ground to the correct size so that when they pass to the checkers in the controlling department there is never more than 1-1000 inch variation in the bore. Cylinders that do not conform to this strict scrutiny are discarded. The pistons and piston rings are required to pass a similar inspection and are finished by the grinding process also. The connecting rods are drop-forged steel of H-section, and the crankshaft, which is a special alloy nickel carbon steel drop forging, undergoes a special heat treatment. The journals, 1 5-8 inches in diameter, are accurately ground and the shaft is supported by five main bearings which are made of babbitt with bronze backings. These bearings are made in halves, and should occasion require they may be removed, replaced or adjusted through the hand holes H shown in Fig. 5 without disturbing the crankshaft. The hand holes are provided with covers which are held in position by two bolts for each. The crankshaft is slightly offset; that is, instead of being placed directly in the vertical plane of the cylinders it is to one side. The object of this is to reduce the angularity of the connecting rod at the time of the explosion, thereby relieving the side thrust on the cylinder walls.

The lubrication of the motor is effected by means of an oiler placed on the left of the motor, as shown in Fig. 5. The extension of the pump shaft passes through this and drives a positive oil pump which forces the oil through a sight feed located on the dashboard. The oil is led thence to the front end of the motor into the timing gear case, whence it flows into the lower half of the crankcase, which has webs cast therein so that the oil is led into sumps under the connecting rods. These latter are

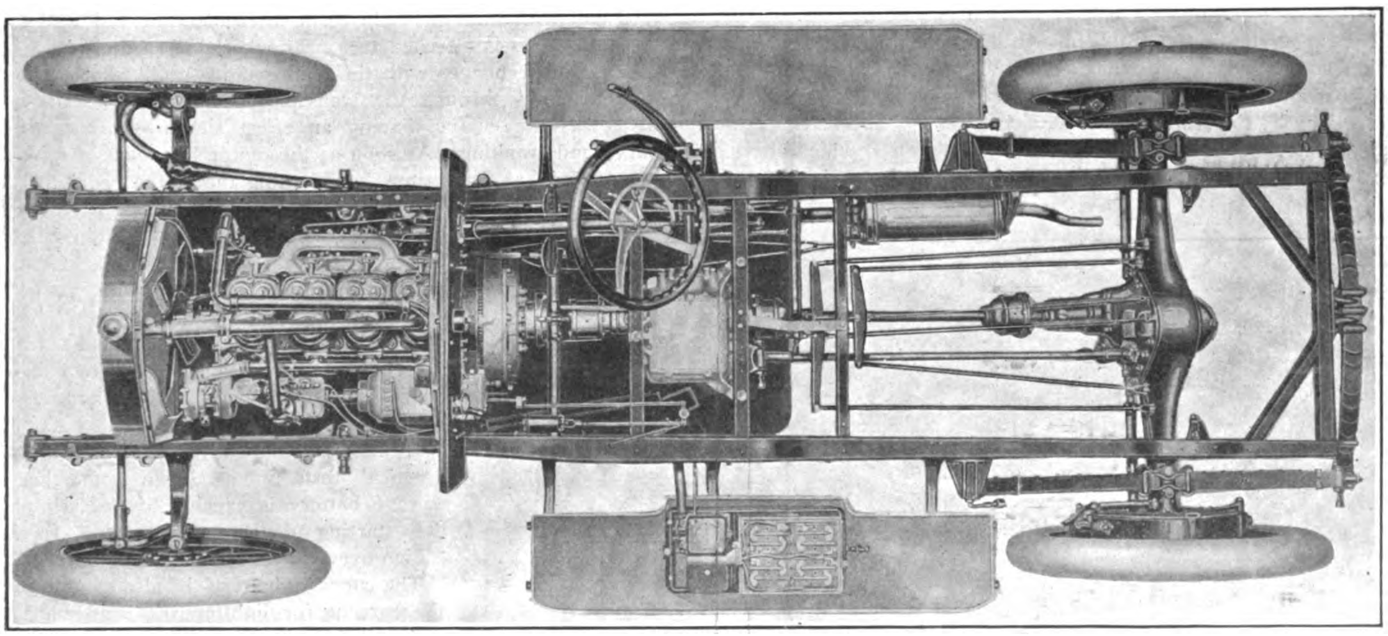

Fig. 7—Plan view of the Cadillac chassis, showing the general characteristics and the co-relation of the various parts

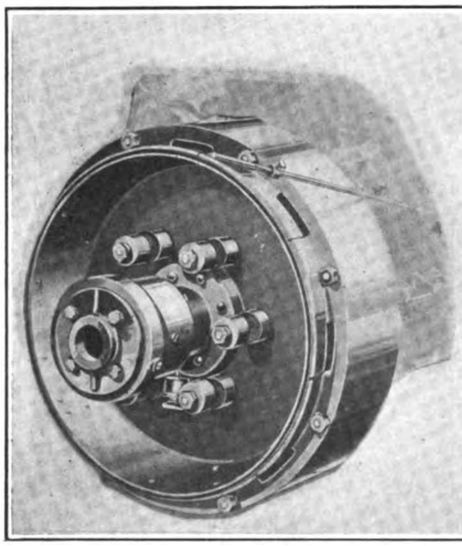

Fig. 8—View of the cone clutch showing how the ring is split for easy starting

Fig. 9—Long change-speed lever working in an H sector

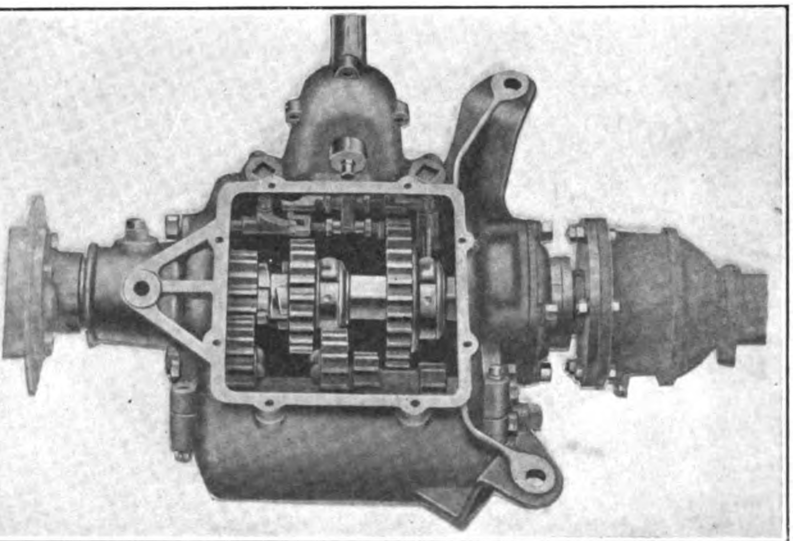

Fig. 10—General view of the gear-box with the cover removed showing the method of support

fitted with extensions that beat the oil at every revolution into a spray for the splash lubrication.

The timing gears have been slightly modified and the cam and idler shafts have been extended so that a bearing can be made in the front cover of the housing. Fig. 6 shows the timing gears with the cover removed. The gear G1 is attached to the crankshaft and causes the gears G2 and G4 to rotate. G2 operates the camshaft and at the rear of this wheel will be seen the bevel gears G3 that command the supplementary ignition. G4 is an idler which meshes with G5. This gear drives the water pump P which is placed in front of the motor, the oil pump, and the Delco ignition system as well as the generator.

The cooling of the motor is effected by means of the water pump just referred to, which takes the water from a vertical tube type radiator placed in front of the motor. The radiator is composed of 150 seamless copper tubes passing vertically through 135 horizontal copper plates and instead of dipping the entire radiator in a bath of molten solder, the tubes are treated so that only the point of contact of the tubes with the plates is covered. The air draft through the radiator is caused by a fan mounted on a bracket B in Fig. 6, wherein a slot is cut to receive the fan shaft. This is maintained in position by means of a nut and permits of easy adjustment. The fan runs on ball bearings and is operated by means of a belt B1, shown in Fig. 2.

The carbureter is of Cadillac design and to insure good evaporation and overcome condensation troubles the mixing chamber has been made exceptionally long and is water jacketed over the entire length; this can be seen at T in Fig. 2. The lever L in Fig. 3, located on the steering column, controls a rod which alters the tension of the automatic air valve spring, giving the driver a ready means of adjustment without leaving the seat; this can be seen at R1 in Fig. 2. The intake manifold has undergone some changes so as to give each cylinder a separate branch from the main manifold.

Two independent ignition systems are provided with two sets of spark plugs placed in valve covers, shown in Fig. 2. The supplementary set shown in this illustration is the Delco distributor system with dry cell current. Fig. 1 gives a comprehensive idea of the main ignition system, the current for which is furnished by the generator G. The timer T is driven by means of bevel gearing from the shaft that passes through the lubricator and the extension of this shaft S drives the generator G. When the speed of the motor falls below approximately 300 revolutions per minute the batteries B are automatically brought into the circuit and the generator power cut out. Above this engine speed the generator delivers the current direct to the high-tension distributor and thence to the plugs. During this time the part G acts as a generator, but to start the engine it can be used as a motor.

This is effected as follows: The driver takes his seat and presses the button on the top of the two-way switch, retards the spark and releases the clutch, which has the effect of making a magnetic contact at the point S. This causes the rod R1 to move forward and with the aid of the lever interposed the rod R2 is drawn back. This is attached to a gear wheel G2 on the generator shaft which engages with the teeth cut in the flywheel and the current flows through the transformed motor and consequently turns the engine, having an effect similar to that of ordinary hand cranking. As soon as the motor has taken a supply of gas and has fired same, by releasing the clutch pedal the gear wheel on the generator shaft flies back and the electric motor again becomes a generator, the current from the batteries being cut out by the automatic controller C. An ammeter is provided at A to show the amount of current stored, the capacity of the batteries being 80 ampere hours, and as soon as this capacity is reached the charging automatically ceases. Some practical tests have shown that the storage battery is capable of operating the starting device and turning the engine over for a period of 20 minutes.

The storage battery B also supplies the current for lighting the head, side and tail lamps as well as the speedometer light.

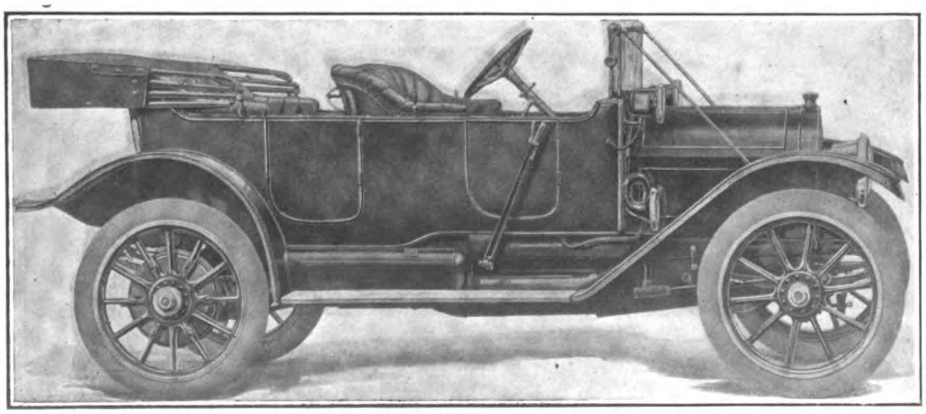

Fig. 11—Fore-door Torpedo body with the gear shift lever placed inside the body line

The motor as a unit is suspended in the chassis frame from three points, the rear of the motor base being bolted at two points to a cross member of the main frame and the forward end is provided with a rocker joint. By this means frame distortions do not affect the alignment of the motor or place any undue strains on the supporting arms.

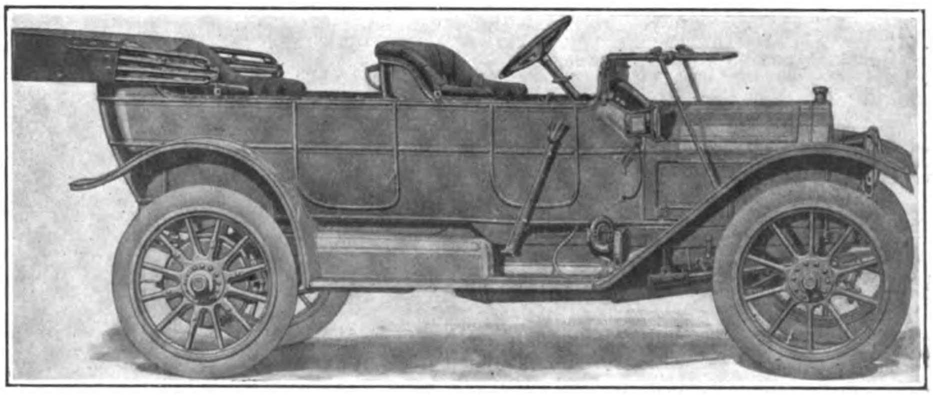

Fig. 12—Standard fore-door touring car fitted to a 30-horsepower Cadillac chassis

The clutch is of the cone type, leather-faced, with a special spring ring in the flywheel, as can be seen by referring to Fig. 8. This ring, with which the cone engages, is split at eight points and part of each section is sprung inward, which has the effect of permitting the clutch to take hold gradually. Interposed between the clutch and the gear box are two universal joints entirely enclosed, thereby retaining the lubricant and excluding any foreign matter.

The transmission with the cover removed is shown in Fig. 10. It is of the sliding gear selective type, giving three speeds forward and one reverse. The gears and shafts are cut from chrome nickel steel and the clutch shaft runs on five annular ball bearings. The second speed gear ratio has been increased and attention has been paid to the method of packing the ends of the casing to prevent the leakage of any lubricant. The housing, which is of cast iron, is supported at two points at the rear to a cross member of the main chassis and at one point at the forward end. The gear teeth are backed off, or beveled, by special machinery to permit of easy engagement, and the change speed lever shown at Fig. 9 has been lengthened. It works in an H-shaped quadrant and is placed inside the fore-door.

The power is transmitted to the differential by means of a propeller shaft fitted with universal joints at both extremities, and the torque is taken care of by means of a tubular V-shaped member terminating at the forward end in a bracket attached to the cross chassis member. When the car is carrying a normal load the drive is practically a straight line from the motor to the rear axle. The rear axle is of Timken construction and is full floating, the drive shafts being made of special alloy steel. The general characteristics of the rear axle and the chassis in general can be seen by referring to Fig. 7. This shows the method of equalizing the service and emergency brakes, both of which operate upon the drums attached to the rear wheels. The diameter of the brake drum is 17 inches and the width of the braking surface is 2 1-2 inches, allowing easy operation.

Fig. 7 also shows the method employed for the suspension of the rear of the chassis, which is of the three-quarter platform type, the transverse spring being attached to the semi-elliptic springs by means of universal shackles all fitted with greasers. The forward suspension is taken care of by conventional semi-elliptic springs 36 inches long.

The size of the tires and wheels has been increased to 36 inches, but the wheelbase remains the same at 116 inches, the same remark applying to the tread, which remains at 56 inches.

The gasoline tank, placed under the driver's seat, has a capacity in the case of the touring and torpedo bodies of 20 gallons, and a gauge is provided on the dashboard to register the contents of the tank.

A Rubber Revolution Promised

AT the London Rubber Show there was exhibited a piece of very excellent vulcanized rubber which had not been produced in the usual manner, it was said, but had been turned out in Brazil by a process by which the rubber was melted and cast, the vulcanization taking place during the cooling. Highly skeptic with regard to the possibility of casting rubber, as reports of similar kind have been circulated many times before, the publishers of the German *Gummi Zeitung* made inquiries in Brazil, and in due time they received a report from C. Meisel, of Para, who was at that time representing a European syndicate in negotiating with the Government of Brazil for the purchase of large tracts of land for *corracha* plantations. Mr. Meisel stated that he had been informed by Dr. Innocencio Hollanda, of Lima, Peru, that an invention promising to revolutionize the rubber industry had really been made by a former *seringueiro* (rubber gatherer), Conrado Ramos Bastos by name, living at Portel, a small town on the Pacajá river. By his process Bastos could simply and quickly produce a high grade of vulcanized rubber from a raw material consisting of *corracha* of many different grades mixed together. Dr. Hollanda showed Mr. Meisel three samples of the man's work; a rubber strap, 20 centimeters long, 15 centimeters wide and 2 millimeters thick, and two pieces in the form of sticks, 15 centimeters long and 1 centimeter in diameter. The color of these pieces was dark blue, and their elasticity was something marvelous. Meisel now sought the inventor and finally found him in a little adobe cabin in poverty-stricken surroundings. He is a very intelligent *cabocolo*, says Mr. Meisel's report, who has worked more than twenty years as *seringueiro* in the virgin forests of the Amazon river district as well as on the Beni river in Bolivia and in Peru. During all this time Bastos has sought for means to transform the many grades of *corracha* into a single typical raw material and also for a simplified method of vulcanization. During the last two years his efforts have been crowned with success, and lately he was requested by the Governor of the State of Para, Exm. Sur. Dr. Joao Luiz A. Goelho, to produce a number of samples in the presence of this gentleman and that of Dr. Huber, director of the Goeldi museum of Para. (Dr. Huber confirmed this by letter direct to the publishers of *Gummi Zeitung*.) The process required 3 1-2 hours, but the inventor worked with the most primitive implements, forming the molds from clay with his own hands and himself preparing the charcoal for the heating. The mixture which he adds to the melted *corracha* is his only secret, and to a representative of the Brazilian Government he is said to have stated that it is made from a substance which is found in inexhaustible quantities in all of the Amazon river valley. To 1 kilogram of *corracha* the inventor adds 1 1-2 to 2 kilograms of this admixture, and the resistance and elasticity of the product is not only not reduced thereby but increased. Mr. Meisel adds that it can only be a question of a few months before the invention must become known and practised on a large scale everywhere.—From *Gummi Zeitung*, September 8.

RAMBLER REFINEMENTS

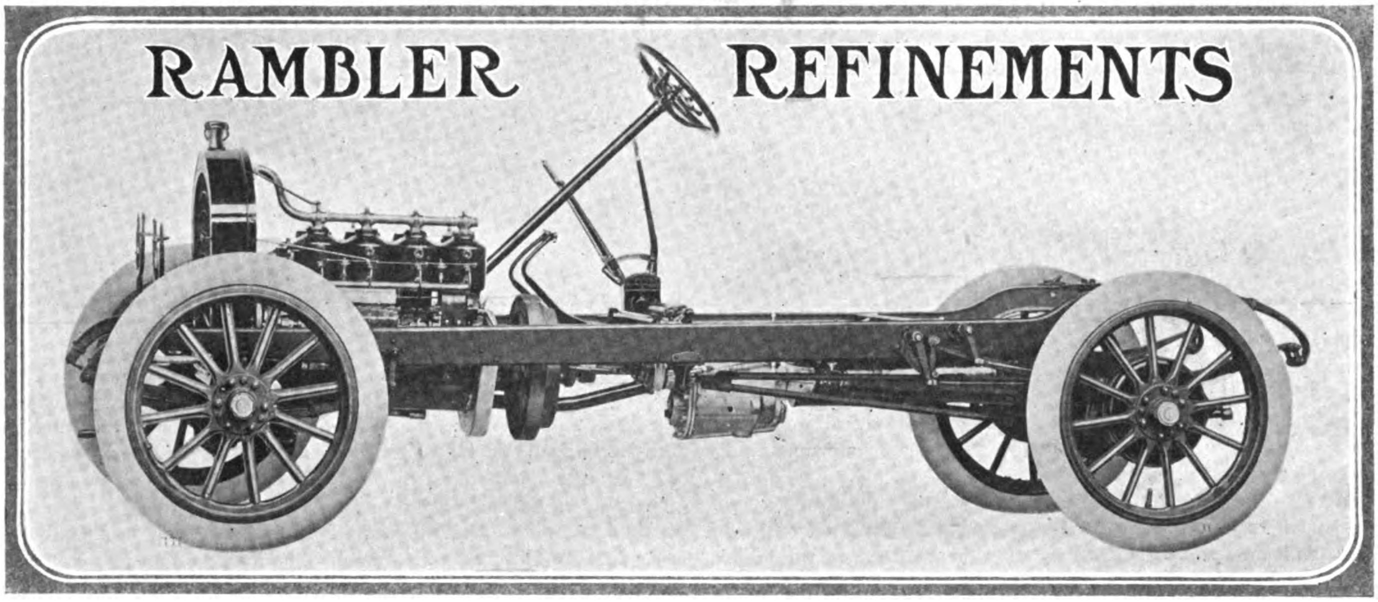

Fig. 1—Side view of the Rambler 38-horsepower chassis, showing the straight line drive and the upswept frame

THE forthcoming season's models of Rambler cars, manufactured by the Thomas B. Jeffery Co., of Kenosha, Wis., discloses a choice of four types of chassis, which with optional bodies provide eleven distinct styles.

The Rambler characteristics are retained, with several detail alterations and improvements. Among these may be mentioned a new I-beam front axle, higher radiator with increased cooling area, positive driven oiler, improved gear-shifting mechanism, a slight alteration in the clutch, strong gusset plates at the rear end of the frame and three-quarter elliptic springs to take care of the rear suspension.

In order to differentiate between the 38-horsepower and the other models that model will first be dealt with.

Each model will be known in future by a name instead of horsepower or series number, and the 38-horsepower model is fitted with three styles of body work. The Cross-Country is fitted with a five-passenger touring body, the Suburban with a four-passenger torpedo and the Roadster, as the name implies, with seating capacity for two.

The wheelbase of the 38-horsepower models is uniform, being 120 inches on all, and the present trend for large wheels has been followed by providing 36-inch wheels fitted with 36 x 4 inch tires.

The front of the car, which is usually the characteristic feature of any automobile, has been materially altered, as may be seen by referring to Fig. 5. The height of the radiator has been increased and a higher filler cap mounted upon it, the contour of the top being given a decided arch. The I-beam front axle is also shown in this illustration, with the cross bar coupling the steering arms placed in the rear of same. Taper roller bearings are employed throughout, both for the wheels to run upon and to take up the thrust of the steering knuckle pins. The starting handle shaft is extended forward so as to clear the dumb irons, two brackets, A1 and A2, being provided to form the outboard support.

Detachable wheels, a feature of Rambler cars, is still retained, but instead of being provided in the general equipment, as heretofore, it is now supplied at a slight extra charge. Provision has been made to carry this part at the rear of the body in the manner shown in Fig. 6, instead of on the running-board, as formerly.

The power plant shown in Fig. 2 discloses several alterations over previous seasons' models. The method of casting the cylinders has been retained; likewise the connection of the joints for the water manifolds. The bore and stroke of the 38-horsepower motor is identical—4½ inches—and the cylinders are cast with L-shaped heads. Some alteration has been made in the arrangement of the timing gears, as well as in the housing. Instead of having the water pump in front of the motor, this part has now been placed nearer to the cylinders and is driven by the half-time shaft, the forward end of which protrudes through the timing gear case shown at T, and the pulley P for driving the fan belt is attached thereto.

The water pump may be seen at P in Fig. 2, and a drain cock D is fitted in the base for emptying tthe water in cold weather or when it may be found necessary. Packing glands are provided at the forward and rear portions of the body of the pump where the shaft passes through.

The continuation of the shaft drives a pump in the oiler O, forcing the oil into the sight feeds S and thence from seven leads—three to the main bearings of the crankshaft and one lead to each cylinder. The method of driving

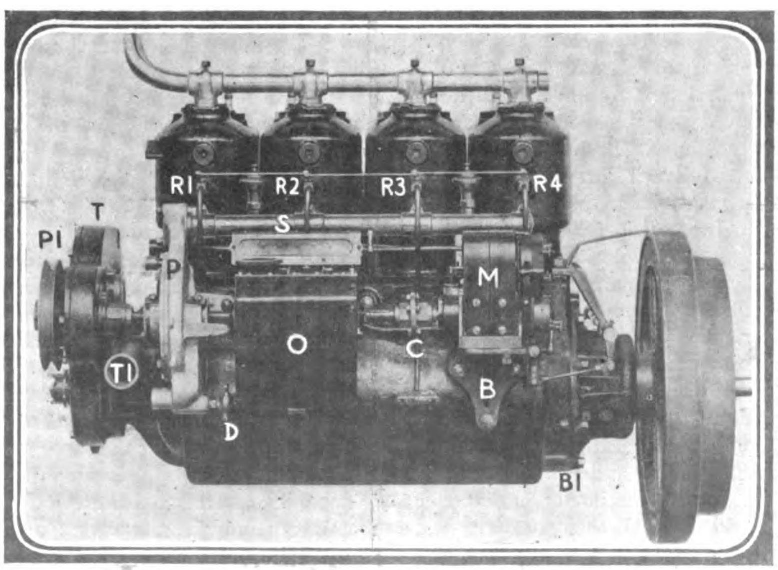

Fig. 2—Side view of the motor, showing the water pump, oiler and magneto

the oiler differs from previous practise, and the magneto M has been placed farther back and is driven by a continuation of the pump and oiler shaft. Interposed in the drive is a universal jointed coupling C, which, besides insuring that disalignment shall not cause any strain on the armature shaft, allows the magneto to be readily removed. Access to the magneto is obtained either by lifting the hood or through a trap door provided in the floor boards.

In Fig. 2 is shown the method of supporting the motor. The tube T1 is built up with the motor base and terminates at either side of the chassis frame in suitable clamps bolted to the side members. By removing the nuts that hold these clamps in position the latter can be slipped over the tubes sufficiently far to clear the frame. A cross member of the frame passes beneath the rear of the motor at the point B1 and bolts pass through it, clamping the rear of the motor in position. A feature of Rambler design lies in the straight line drive from motor to rear axle, and to obtain the requisite amount of slant to the motor, babbitt is run in between the motor base and the cross member until the correct alignment is reached.

Compression release cocks R1, R2, R3 and R4, are fitted to permit of easy starting, the residue of compression being carried by small copper pipes to the side of the motor and the operating lever controlling the cocks is placed on the side of the radiator.

Ignition is furnished by a high-tension magneto, the position of which has already been described. Carburetion is effected by means of a Holley carbureter and a manifold of improved construction, doing away with the loops over the motor.

The clutch shown in Fig. 3 has also undergone some minor changes, although in principle it is virtually the same as that adopted last year. It is of the internal expanding type and operates inside the fly-wheel. The clutch pedal and arm force the arms A1 and A2 forward, which has the effect of rocking the arm D so as to relieve the tension of the spring S. At the same time the action of the part D causes the shaft S3 to rotate slightly, sufficient to rock the arm A, which commands the ball sockets B and B1, thereby contracting the band B, which is attached to the shoe S2.

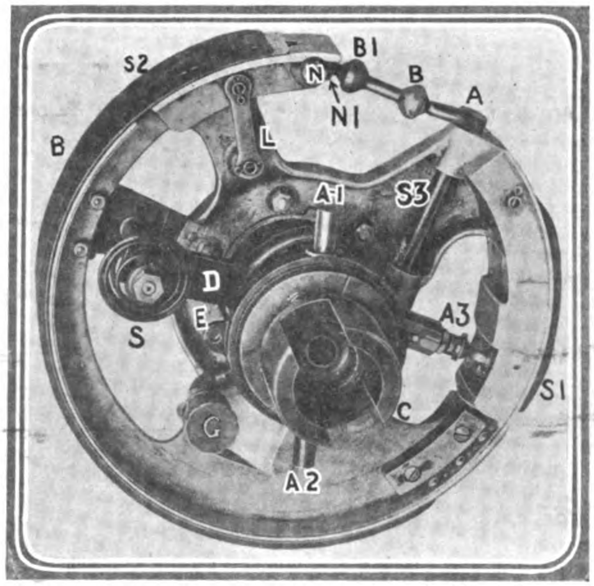

Fig. 3—Details of expanding clutch, showing the two adjustments

The adjustment of the expansion of the clutch is effected by means of the nut N1, which is locked in position by the set-screw N. The lever L prevents the shoe S2 from swinging back and causing abrupt engagement, as well as the shoe S1, which is operated by a small toggle joint A3 at the same time as the main body of the band B. This latter part is also fitted with a means of adjustment. The drive is taken by the collar C, which engages with the forward end of the shaft, communicating the drive to the gear box. The arms A1 and A2 form part of a ball-thrust collar, which is held in position by a tie rod from the main frame to the eye E and lubricated by the greaser G. When the clutch pedal is released the expansion of the band is maintained by the spring S.

The plan view of the chassis, Fig. 4, shows the general assembly of the motor, clutch, gearset and rear axle, and Fig. 1 gives an idea of the straight-line drive. The gear-box is attached at its forward extremity to the central cross member of the frame and the aluminum housing of the gear-box is cast on to the tube surrounding the propeller shaft. The main shaft of the gearset is a continuation of the propeller shaft and the change of gear is now effected by a straight-line pull upon the shifting rods. Two arms attached to these are fitted by means of brackets to the propeller shaft casing, as may be seen in Fig. 4. The change-speed lever, as well as the brake lever, have been placed within the body line, and as the gears are of the selective type, the gear-shift lever works in an H-type sector. Three forward speeds and reverse are provided.

The final drive is by live rear axle, the weight of the load being taken upon roller bearings. The drive shafts and the gears are forged integral and the road wheels are secured to

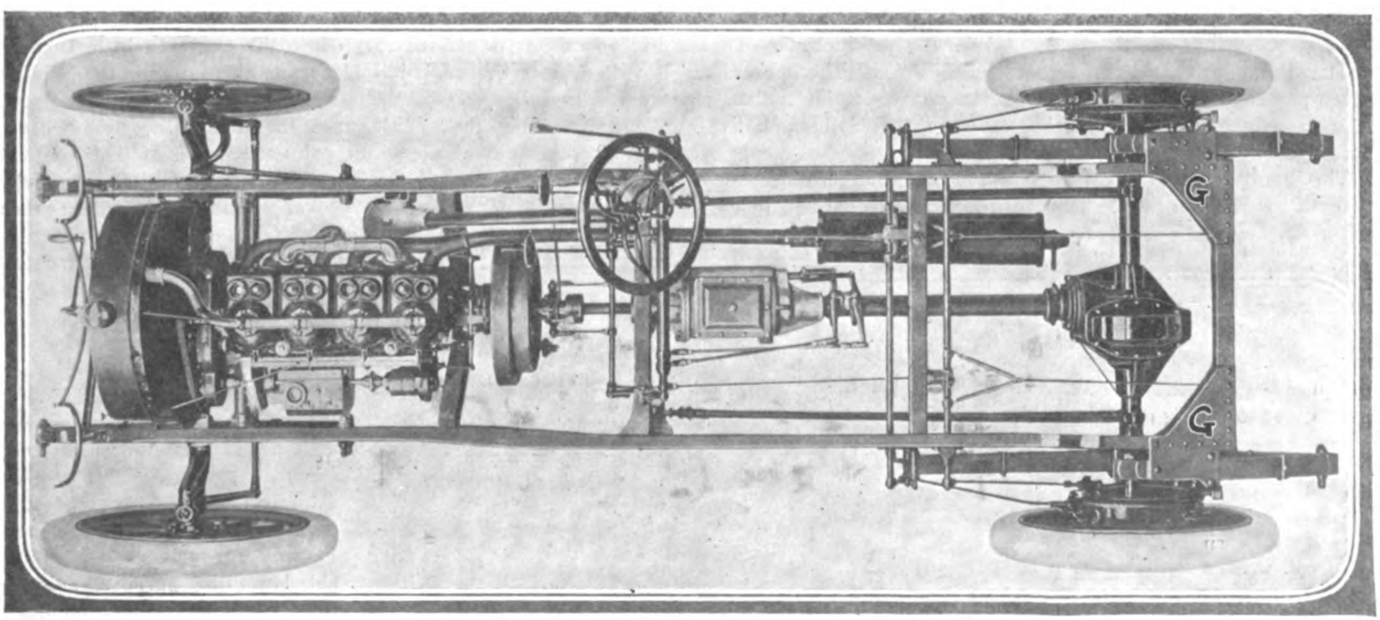

Fig. 4—Plan view of the Rambler chassis, showing the co-relation of the various units

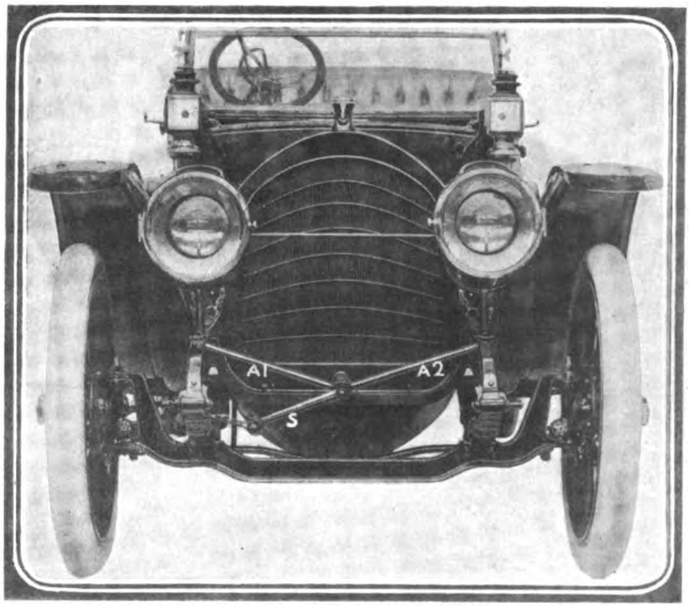

Fig. 5—Front view of the new Rambler, showing the radiator and the outbound supports for the starting handle

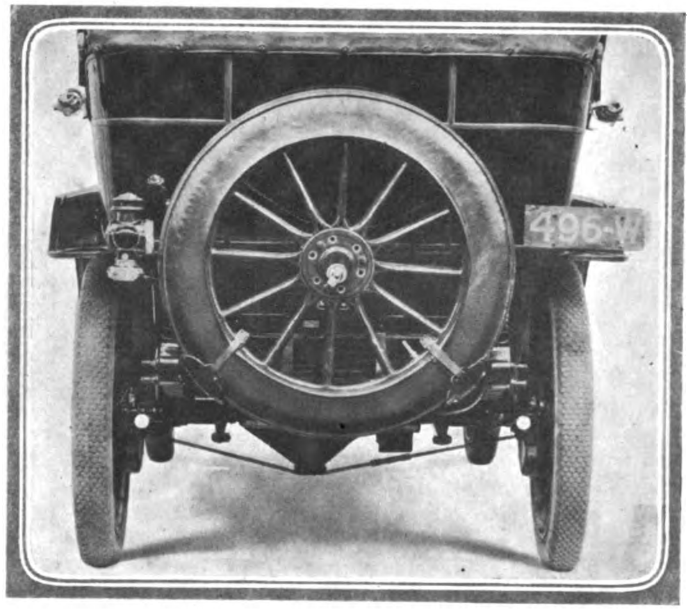

Fig. 6—View of the rear of the car, showing the method employed in carrying the spare wheel

the ends of the shafts by means of squared taper ends. Stout gusset plates have been incorporated in the construction of the rear end of the frame, as shown in Fig. 4, the extensions of which form the anchorage of the top brace of the three-quarter elliptic springs. The torque of the rear axle is taken up in the two radius rods, terminating at their forward extremities in ball sockets, permitting of a certain amount of angularity without causing any binding effect.

Two sets of fully equalized brakes are provided, both operating upon the brake drums attached to the read road wheels.

The essential features described above apply in general to the 50-horsepower models, the motor of which has a bore of 5 inches and a stroke of 5½ inches. Dual system of ignition is employed, and in the case of the Metropolitan, Greyhound and Moraine, the size of the wheels is 40 inches in diameter.

The Country Club, Valkyrie and Moraine are fitted to one type of chassis, having a tubular front axle and seven-eighths elliptic spring suspension at the rear. The first two of these are fitted with 36-inch wheels and have a 120-inch wheelbase; the Moraine, which is a seven-passenger touring car, has 128-inch wheelbase. The Metropolitan, a seven-passenger touring car, and the Greyhound, a six-passenger, are fitted with three-quarter elliptic springs and have a wheelbase of 128 inches.

The Rambler closed-car line includes the Knickerbocker, a seven-passenger limousine of the Berline type; the Sedan, a four-passenger with closed cab seats, and the Gotham, a five-passenger limousine with cab sides.

The standard coloring of the majority of the Rambler body types is an English purple lake with black beads striped in carmine, with the metal furnishings nickel finished. The fenders and valance fillers are japanned black. An option, however, is given in the majority of styles for the customers who prefer a lighter coloring, and for these Brewster green can be furnished, as also can a certain shade of gray, known as Rambler gray, in the case of the Roadster.

The equipment of the cars includes head lamp with gas tank, side lamps, tonneau hinged robe rail, adjustable foot rest and complete set of tools. The Roadster has a trunk with suit cases placed on the rear platform. The interior of the closed cars is trimmed in Bedford cord and some of the fittings include silk blinds on automatic rollers, electric dome light in the ceiling, toilet case and speaking tube.

Winter Storage of Car

WHEN the use of the car is given up for the cold weather season, the car should be jacked up off of the tires, some air let out of them so as to reduce the pressure, and the whole washed very thoroughly, particular attention being paid to the removal of all traces of oil. Water does not harm the tires or the rubber composing them in the least, but oil and gasoline do. In case it is desired to go into the matter a little further, and do a more thorough job of putting them up for the Winter, proceed as follows:

After washing thoroughly, take the tires off of the wheels, take the tubes out of the shoes, paint the inside of the shoe and the outside of the tube with graphite, wrap both very carefully in cloth or heavy paper, paper over cloth being the best, then store in some dry, dark place, preferably where the temperature is very even all Winter and not far from 30 degrees Fahrenheit. Light is a great enemy of rubber, as is also heat; by putting the protective covering around the tires, then keeping them away from light and heat, there will be absolutely no deterioration, no matter how long they may be kept put away. This method of procedure is really worth the time it takes. Of course, none of the ordinary oils used for paint bodies would be suitable for this purpose, as they would rot the rubber. What is meant by painting with graphite is that it should be applied in its powder form.

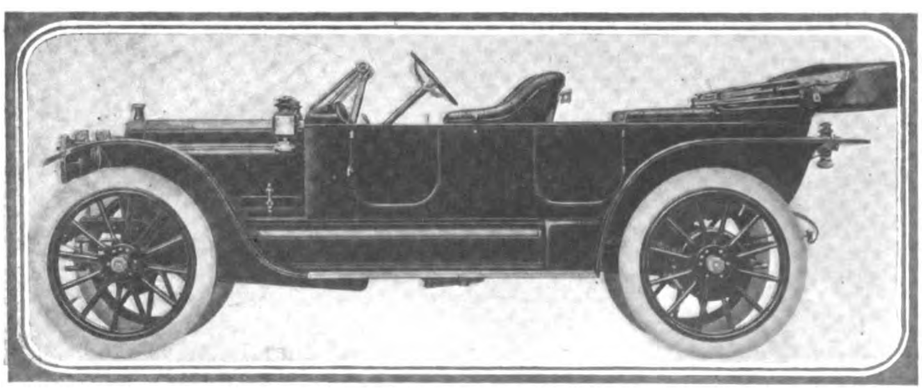

Fig. 7—General appearance of the Greyhound Rambler with fore doors and sloping cowl

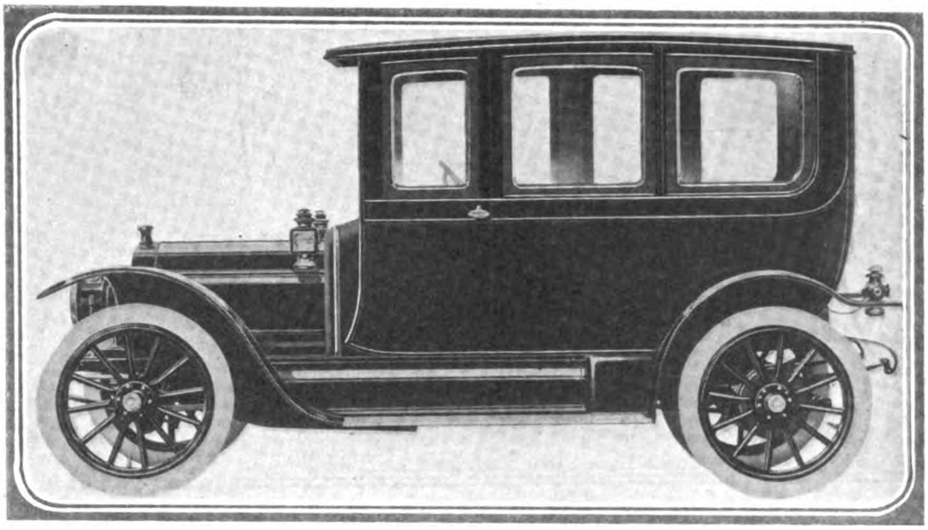

Fig. 8—Side view of the sedan body fitted to a Rambler Chassis with a single door

PREVENTABLE BREAKDOWNS—There are road breakdowns which, although apparently not the fault of the car owner or driver, will on examination show that they could have been prevented if proper precaution had been taken. One instance which may be taken is the damage which ensues from a broken ball in a bearing. The breakage of other balls and the grinding of the race could have readily been prevented by even a casual inspection before starting upon the trip. Cleaning the ball bearings in order to remove every particle of grit from the race is as essential as the lubrication of the bearing. No one would think of allowing a bearing to run without oil, yet many neglect the cleaning of the bearings, an operation that is in every way as important, even though it is never required more often than about once in two weeks. Many a trifling knock which would have soon developed into something serious, and many an impending stripped gear has been forestalled at an expenditure which is far less than it would have been if the owner had waited until the accident had occurred. The car should never leave the garage without the full confidence of the owner that it is in the best state of repair and adjustment and that it is clean.

Among the New Books

TEXT BOOK OF THE ELEMENTS OF MACHINE WORK. By Robert H. Smith, Massachusetts Institute of Technology. Published by Industrial Education Book Co., Boston, Mass. 192 pages, 5 x 8, 204 illustrations. Cloth, $2.00.

The fundamental principles of bench work have been taken up in this copiously illustrated book as well as the elements of machine practice and mechanical drawing. The book consists of 371 numbered paragraphs, each headed by a topic sentence in bold-faced type. A classified table of contents and an alphabetical index guide the reader or student in his perusal of the work or in his search for a particular item.

The book is complete enough to be used as an elementary reference work for the apprentice or student of shop practice. A table of decimal equivalents concludes this useful book, which will no doubt find favor with those interested in the subject matter treated.

QUESTIONS AND ANSWERS FOR AUTOMOBILE STUDENTS AND MECHANICS. By Thomas Russell, A.M., M.E. Published by The Charles C. Thompson Co., Chicago. 150 pages. Leather, $1.50; cloth, $1.00.

While undoubtedly a book intended only for students of automobiles and automobiling, its completeness would justify a position in any library on this interesting subject. The questions are terse and are answered in such a way that there is no doubt as to the meaning intended. Mr. Russell, who has written other works on this and kindred subjects, has aimed to bring out the salient features in each part upon which he has touched, and he has done so, as will be demonstrated by a perusal of the work.

A separation of the questions and answers renders the book very satisfactory for self-instruction, and by its completeness it is made fully capable of being used as a text book. Its scope is very wide, taking up first the motor car in general and then covering the different essential details.

TEXT BOOK OF THE PRINCIPLES OF MACHINE WORK. By Robert H. Smith, Massachusetts Institute of Technology. Pub. lished by Industrial Education Book Co., Boston, Mass. 388 pages, 5 x 8, 434 illustrations. Cloth, $3.00.

The uses of the various tools connected with the various operations at the bench and at the various machines are here brought to the reader in a clear and concise form which will be very much appreciated by the student of machine work. The work is profusely illustrated in such a manner that the methods of carrying out the operations are brought vividly to the mind of the student. The methods of making the calculations involved in practical work are also shown and typical examples given to augment their usefulness.

As a reference work this book should have as large a field as when used as a text book since it is very complete so far as the ordinary shop undertakings are concerned and is well indexed. A set of tables and data of a very useful nature conclude the work.

AUDEL'S ANSWERS ON AUTOMOBILES. By Gideon Harris and Associates. Published by Theo. Audel & Co., New York. 476 pages, 380 illustrations. Cloth, $1.50.

In this work a very complete set of questions and answers are furnished. The topics dealt with range from questions and replies on fuels to information on the driving and mechanical arrangement of the automobile.

Each chapter is introduced by explanatory remarks on the subjects contained therein, and is amply illustrated. The book as a whole is very satisfactory and will no doubt find its way into the libraries of those who wish a concise, well-written book treating of the details of the construction and upkeep of the automobile.

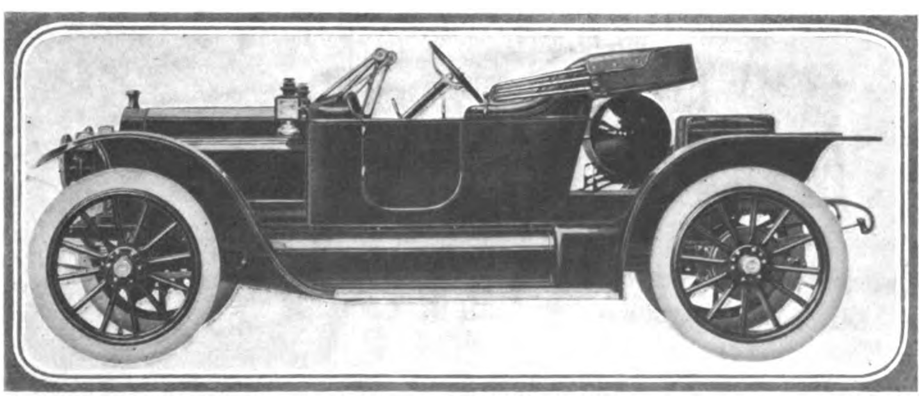

Fig. 9—Side view of the fore-door Rambler with gasoline tank placed behind the driver's seat as well as the trunk with suit cases

Fig. 1—The C. I. M. A. tractor has a motor with 10-inch bore and 15-inch stroke

Adapting the Motor to Farm Uses

French Agricultural Motors

AUTOMOBILE clubs in France are finding a large field for work in arranging trials for agricultural motor machinery and implements. In a contest recently held at Roubaix by the Automobile Club de France in co-operation with the Automobile Club du Nord and the Association of French Manufacturers of Agricultural Implements, the machines submitted for test were two tractors, the Cima and the Lefebvre, made at Rouen; a motor plough made by P. Gilbert, Paris, and another motor plough made by Landrin of Soissons. Both the ploughs are of the revolving-disk type. A Linard-Hubert motor plough had also been entered, but was prevented from taking part in the trials. According to the report rendered by the committee on agricultural machinery of the Automobile Club de France, the features considered in the contest by the judges were: First, the execution of the work; second, the cost of the fuel or energy (electric current) consumed in tilling 1 hectare of land (1 hectare equals 2.471 acres); third, the time required for transportation and getting ready; fourth, the number of workmen necessary for operating the implement; fifth, the facilities for using the implement under different conditions of soil and surface, and, sixth, the possibility of utilizing the motor of the implement for other agricultural work.

To obtain a basis for comparison among the different machines all of them were required to work at a minimum depth of 15 centimeters (5.906 inches). The fields used for the trials on the first day were in stubble, while those worked on the second day had been turned over, and the soil was found particularly hard and dry, being thin with a clay subsoil, which rendered it necessary to make the furrows relatively shallow. The agricultural experts pronounced the conditions highly unfavorable. The shape and size of the fields necessitated too frequent half-turns for machines especially intended for work on large farms, and the cost of the work per hectare was considerably increased by this condition. It was ascertained that the strip of land left untilled at the edge of the fields, by reason of the space required for turns, reached a width of 36 to 45 feet in the case of the Cima tractor, 45 feet for the Lefebvre tractor and 6 to 15 feet for the two ploughs. In the case of the ploughs this width of waste area may be further reduced by backing them up, with the rotary disks raised. The time used in making a turn, counting from the finish of one furrow to the beginning of another, was 1 minute 20 seconds for the Cima tractor (also known as the Osborne, being apparently of English or American origin), 2 minutes for the Landrin plough, 2 minutes 30 seconds for the Lefebvre tractor, while the Gilbert plough drew a continuous furrow, describing a rectangle with rounded corners.

The Cima obtained the gold medal of the Association of Automobile Manufacturers and the silver medal of the Association of French Manufacturers of Agricultural Machinery. The Landrin got the silver-gilt medal of the Department of Agriculture and one-half of the prize offered by the Agricultural Society of France; also the silver medal of the A. F. M. A. M. The Lefebvre got the silver-gilt medal and the other half of the prize of the Agricultural Society as well as the silver medal of the A. F. M. A. M. The Gilbert finally obtained the silver medal of the Department of Agriculture and the silver medal of the Agricultural Society. Several mechanics connected with the trial received individual awards.

Fig. 2—Landrin rotary-disk plough and tractor

The contesting machines, some of which are shown in the accompanying illustrations, are described by the club committee substantially as follows:

The Cima, or Osborne, tractor carries a 25-horsepower horizontal motor with two flywheels, of the type ordinarily employed for industrial purposes, and the power of the motor is transmitted to the two large rear wheels by trains of gears thrown into engagement by a friction clutch. The small front wheels are steered by chains from a steering post at the rear of the vehicle, so that the driver at the same time can watch the course of the tractor and the operation of the plough. The motor cylinders are of 254 mm. (10 inches) bore and 381 mm. (15 inches) stroke. The crankshaft speed varies from 230 to 290 revolutions per minute, and the diameter of the flywheels is 1.33 meter (4 feet 4 inches). The driving wheels measure 1.75 meters (5 feet 8¼ inches) in diameter, with a tire width of 0.55 meter (1 foot 9½ inches). In case of excessive humidity in the soil extension rims can be put on the driving wheels, bringing the tire width to 0.75 meter (2 feet 5¼ inches). The all-over measurements of the tractor are 4.96 meters (16.5 feet) in length and 2.46 meters (8.2 feet) in width. In the trials the plough drawn by the tractor was a Mogul with five shares, any one of which can be raised and taken out of use independently, and the moldboards are arranged to raise themselves if a rock in the ground or other obstacle is encountered. The Cima requires three attendants for operation with a plough.

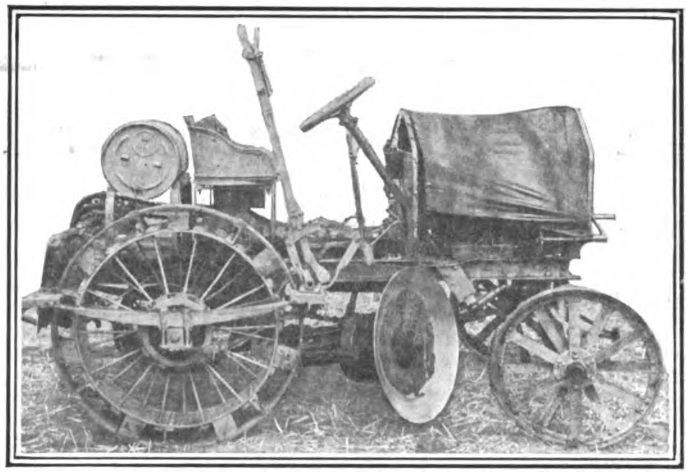

Fig. 3—Gilbert's plough combined with tractor

The Landrin rotary-disk plough or cultivator (Fig. 2) comprises two distinct parts, the motor chassis and the cultivator chassis. The motor chassis differs from an ordinary automobile chassis in the following features: The driving wheels are equipped with movable cleats (traction ribs) mounted around an eccentric which serves to either push the cleats out from the surface of the wheel rim or to draw them back, the eccentric being so placed that the cleats project from the rim where the latter is going, into contact with the ground and recede when the contact has taken place. The object is of course to increase the adhesion, but also to remove automatically the soil which may cling to the cleats. By means of a suitable displacement of the eccentric the action can be reversed, so that the projecting ribs recede at the point of contact with the ground, and this facilitates the travel of the cultivator on hard roads. The motor chassis supports a winch intended to raise the cultivator chassis by means of a cable, and a worm gear renders this winch irreversible. The conductor can throw the motor shaft into gear with the winch by means of a lever within his reach, and thus by a single movement stop and resume work, as at turns.

The cultivator chassis is triangular in shape, and the base parallels a shaft on which four steel disks are secured, and the apex of the triangle is connected with the motor chassis by means of a joint which admits of all movements except forward. The disk-actuating shaft is similarly articulated by means of a cardan joint. The disks themselves are shaped as segments of a sphere and are mounted at equal intervals, the shaft being placed at an angle with the driving wheel shaft varying from 20° to 40° and subject to adjustment according to the position given a bar, provided with various adjustment holes, which connects the cultivator chassis with the hub of the right-hand driving wheel. The depth of the disk action in the soil may be regulated by two rollers and two threaded rods supporting each one end of the disk shaft.

Gilbert's self-propelling plough Fig. 3 is meant for doing all the work in preparing soil for seeding, and the designer has had in mind to accomplish this purpose with a relatively light construction, while providing means to prevent the oblique thrust of the rotating disk from influencing the direction of the machine and also for enabling the driver to watch and regulate the operation of the machine. Of the two rear wheels only the one on the right-hand side is a driving wheel, the left one serving only for support. The front axle is secured to the chassis by a system of joints in such manner that the steering wheels may follow all the inequalities of the soil without changing the horizontal position of the chassis, and the wheels are offset to the right, so that the driving wheel tracks the width of one furrow to the left of the right hand front wheel. The disk, in the shape of a spherical segment, is secured to the chassis between the front and rear wheels by means of an arm, and a transverse shaft around which the arm turns when raising or lowering the disk may also serve as axle for the left rear wheel, this being the method adopted for securing a horizontal position of the chassis, when the machine is at work as well as on the road. The motor drives the disk as well as the driving wheel. The mechanical connection with the disk is effected by a spurwheel and a bevel pinion, running in a casing, and the pinion is connected with the vehicle transmission by a removable chain, so that a simple play of gears permits the driver to adjust the speed of the disk to the nature of the soil and the rate of progress of the vehicle. On the road the chain may be removed. The disk turns in the direction opposite to the movement of the vehicle and at a superior speed, with a view to turning the soil over in a work-

(*Continued on page* 683.)

Letters Answered and Discussed

Measuring Compression Space

EDITOR THE AUTOMOBILE:

[2,868]—Would you kindly inform me if there is any gauge which is made for the purpose of measuring the compression space in the different cylinders to ascertain whether it is the same in all of them?

(2) What would be the results which would arise in case these compression spaces were not equal?

(3) How is it possible to determine when the piston on a certain cylinder has reached the top of its stroke?

I have a four-cylinder motor of 30-horsepower and I wish to ascertain if the compression is the same in all the cylinders, as the motor has been run for a considerable length of time and I am afraid that there has been considerable wear.

CARL KEISER.

Portland, Me.

(1) A gauge which will be familiar to any one who has worked about a carpenter shop to any extent may be used to advantage in measuring the piston clearance of the cylinders. The gauge and the manner of inserting in the pet cock aperture are shown in Fig. 1. The motor is slowly turned over, and when the spindle has been pushed by the piston as far as possible through the cross piece of the gauge, which is held flat against the top of the cylinder, a reading may be taken off the spindle and the clearance of the piston plus the thickness of the walls and water jacket space will be given. A note is made of this reading or the gauge may be nicked at the point where the gauge registered with the cross piece. This can then be checked in the other cylinders and should agree exactly.

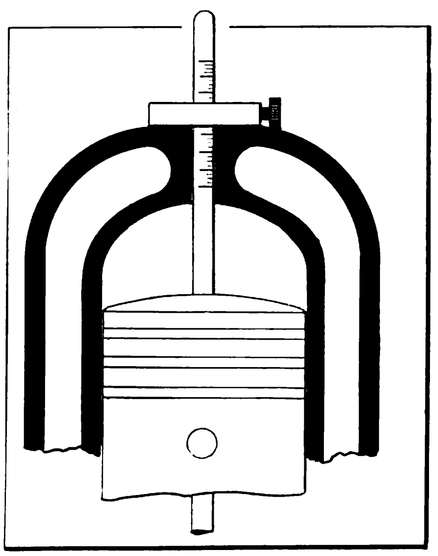

Fig. 1—Gauge used in testing the compression space in the motor

(2) In case the compression spaces differed the motor would be out of balance and the impulses on the cranks would differ in force. Vibration and rocking of the motor on its foundations would be the natural result of the unbalanced forces.

(3) The piston has reached the top of the stroke when it ceases to push the gauge. There are very often marks on the flywheel which denote the dead centers of the engine when they register with marks on the frame of the motor.

The fact that your motor has been run for a long time does not indicate that there has been any change in the relative compression space, as whatever wear there has been will no doubt have equalized itself by wearing the corresponding parts in all the cylinders a like amount. If there is anything wrong with the compression it will probably be in the nature of a worn valve seat or valve which needs regrinding or in leaky plugs and other openings into the cylinder.

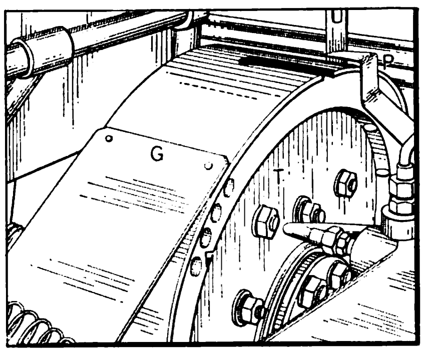

Fig. 2—Guard placed over the flywheel to prevent oil slinging

Needs Mud Guard

Editor THE AUTOMOBILE:

[2,869]—I am driving a truck and am much troubled by the oil being thrown about by the flywheel. Could you tell me of a method of stopping this? The oil will leak up through the floor boards and completely soak through anything which happens to be resting upon them. Besides this the dirt will adhere to the oil and cause a great deal of trouble in keeping the truck clean.

M. F.

New York City.

A mud guard such as is indicated at G in Fig. 2 should be fitted. This consists of a flat piece of tin which is carried across the flywheel and fastened to the chassis frame by means of bolts. A groove is cut as shown in the guard, so that the markings on the flywheel will be visible below the indicator P and when setting up the engine the correct timing may be maintained without trouble.

Fitted New Carbureter

Editor THE AUTOMOBILE:

[2,870]—I have a 1906 car which I have changed over to a jump spark and have also fitted a new make of carbureter. It runs very well on level ground and takes most hills on high speed. But sometimes when taking a long one on high speed it will choke up and fire only on three cylinders. After the engine has been allowed to speed up by throwing out the clutch, when the top of the hill is reached, it will once more hit on all four cylinders. Could you tell me the trouble?

2. What was the horsepower of the car which won the 1910 Grand Prix?

New York City. A. E. W.

The probabilities are that you have used a carbureter too small for the engine to which you have fitted it. You are not getting enough air and too much gasoline.

2. The horsepower of the car which won the 1910 Grand Prix was 120 by the maker's rating and 63 by the A. L. A. M.

Deprecates Crowned Roads

Editor THE AUTOMOBILE:

[2,871]—In your paper for September 28, under the heading "Good Roads," I could not but notice the favor shown for crowning roads for the automobile. In Los Angeles they are doing their best to build good roads of which our people are justly proud. But the crowned roads are not good nor safe for automobiles; any road that is too much crowned for horses is too much so for automobiles, and that is not all. In California we are compelled to keep to the right of the center of the road and as near to the gutter as practicable. Consequently the right side of the machine, being several inches lower than the opposite side, must support a greater amount of weight. The result is that the tires on the side next to the gutter give out much more quickly than the tires on the opposite side of the machine.

Many cars are not absolutely grease-proof, and the right side of the machine running on the lower incline causes the grease that works out from the differential to find the lower level, thereby interfering with the brake and in some cases dropping out and finding its resting place on the tire, while on the opposite side of the machine the brake shows no sign of superfluous grease. The springs also show wear, having a constant pressure to the right. The crowned roads are costing the automobile owners thousands of dollars every year. Many of your readers may not have given the subject much thought, but they must have wondered why the tires gave out first on the right side of the machine.

T. J. BOSSERT.

Hollywood, Cal.

Likes the Slide Valve

Editor THE AUTOMOBILE:

[2,872]—Will you please tell me if there is any patent extant on a working model of a slide valve gasoline motor of the four-cycle type? If there is what objection is there to the adoption of this type of valve?

I am working on a slide valve engine model and to all appearances it is a far superior piece of mechanism to the common poppet valve. I would be very glad to have your opinion on this scheme.

CHAS. F. WHYTE.

Saxonville, Mass.

Types of slide valves have been tried in connection with the gasoline motor, but none as yet has been proven capable of working under the conditions which obtain in automobile practice. The sleeve valve which has gained favor lately is the nearest approach to it which has been put into practical use. There is doubtless a field for very profitable work in connection with this part of the gas engine and the adoption of the slide valve is well within the realms of possibility.

Removing Broken Screws

Editor THE AUTOMOBILE:

[2,873]—The screws which hold the clutch box together on my car are broken off and I cannot remove them by means of a screw driver. The clutch is of the multiple-disc type and the box is held together by means of two narrow flanges which are held by screws which pass through them. Would you kindly tell me how I may remove them and replace them with new ones? M. F. B.

Cornwall, N. Y.

The remedy which may best be applied to a case of this nature, where the screws are apt to be very small, is to take a breast drill and take the screws out altogether by drilling. This is done in the manner shown in Fig. 3. Small bolts may then be fitted in place of screws or, if it is so desired, the new holes can be tapped and other screws fitted.

The drill employed should be about the same size as the screws, so that more material than is necessary will not be cut away.

Does No Harm

Editor THE AUTOMOBILE:

[2,874]—Please advise in your answers to subscribers if it will do any harm to either the storage battery or magneto to have both on at one time. My car is fitted with a high-tension magneto, separately connected with one set of plugs and a storage battery connected with another set of plugs. G. H. SMITH.

Roulette, Pa.

It will do no harm to run both sets of spark plugs at the same time if you so desire.

Points of Wear

Editor THE AUTOMOBILE:

[2,875]—Would you kindly tell me the points that are liable to wear in the cam and follower mechanism?

(2) Is a cam shaft which is oiled by the splash system apt to be given an entirely adequate amount of oil, or should there be some independent means of supplying oil to the bearings of this shaft?

Newark, N. J. A. R. L.

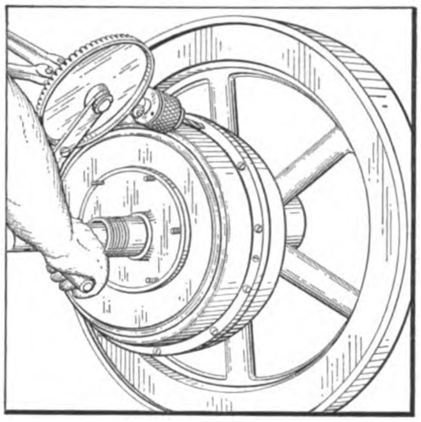

Fig. 3—Method of drilling holes through broken screws in flange

(1) The wear will be found to occur on the cams at the point which first strikes the follower. This point is shown to be just about to be reached in Fig. 4. The roller follower will often wear, as will the push rod bushing, end of the push rod, pivot bushing and the top of the push rod. Wear in the push rod can generally be taken up by special means generally fitted to make these adjustments.

(2) A cam shaft that is lubricated by splash will receive plenty of oil to thoroughly lubricate it.

Idea Arouses Interest

Editor THE AUTOMOBILE:

[2,876]—In your issue of Sept. 7, Robt. W. Hughs, in describing the "eventual" car, mentions a recently patented gear-shifting device. (See page 397.)

May I ask you to describe and illustrate this if of sufficient importance. I feel sure many car owners would be interested.

D. B. GREENE.

Neosho, Wis.

[We suggest that you communicate direct with Mr. Hughs, whose address is Atlanta, Ga.—ED.]

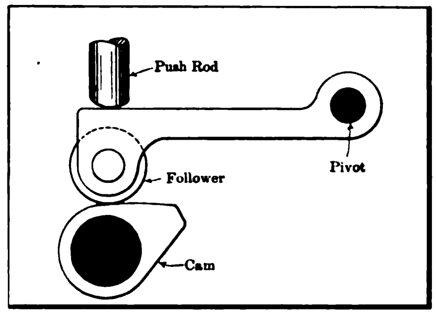

Fig. 4—Showing the wearing points of the valve lifter mechanism

Also Likes Idea

Editor THE AUTOMOBILE:

[2,877]—I should like you to give me further particulars through your columns as to the patent which has been taken out to eliminate the change gear's lever. According to one of the correspondents who described his ideal 1912 car such a patent has been taken out and when it is in general use it will eliminate the need of this part, as the change of gear will be entirely automatic. I have not seen this contrivance referred to except in this article.

F. D. MARTIN.

New York City.

Good Advice

Editor THE AUTOMOBILE:

[2,878]—Several of my friends who drive cars have advised me to release the clutch on rounding a curve, saying that in doing so I will save tire expense. Is this true? If it is, could you tell me the reasons?

CHAS. CAMDEN.

Trenton, N. J.

The advice that your friends have given you is good. In slipping the clutch you will not only decrease the tendency of the car to skid, thus partly eliminating a cause of tire depreciation, but the lateral strains involved when the motor is driving the car when turning a corner will also be dispensed with. There are many little opportunies which are afforded to drivers to lighten their tire and other expenses by the use of a little foresight and care and this is one of them.

Wants Views of Others.

Editor THE AUTOMOBILE:

[2,879]—I have noticed a great deal of discussion lately among those who are interested in automobiling concerning the merits of the use of carbonic acid gas in tires. Many people state that it will leak from the tire at an alarming rate and others assert that this is much exaggerated although true to a slight degree. I would like to know some of your readers' experiences in this matter. J. E. S.

New York City.

Views of our readers on this subject would no doubt be appreciated by many who are interested in this matter.—Editor.

My 1912 Automobile

Some Conceptions of What the Ideal Car Should Be

A Brooklynite's Ideal

Editor The Automobile:

The ideal car should have a unit power plant. The motor should have four cylinders cast in pairs, having a bore of 4¾ inches and a stroke of 6½ inches. The valves should be about 2¾ inches in diameter. The motor should be of the T-head type, with the valves enclosed. The valves should have adjustable lifts. There should be a five-bearing crank and cam shaft, the bearings being of bronze with babbitt lining.

The lubrication should be by the automatic splash system, the supply being maintained by a mechanical force-feed lubricator with sight feed on dash.

Ignition should be by Bosch magneto and storage batteries. There should be two sets of spark plugs over valves with an arrangement for cutting off cylinders.

The water should be cooled by a square-tubed honeycomb radiator and a four-bladed fan and circulated by a gear-driven pump.

The clutch should be a multiple disc type running in oil. It should have about sixty plates. There should be a four-speed transmission mounted on ball bearings. Direct speed should be on third.

The car should be shaft-driven with a Timken-Detroit rear axle. Roller bearings should be used with it. The front axle should be of the B. and L. Caster type.

Steering should be by an irreversible worm and sector gear. The steering wheel should be 18 inches in diameter with a corrugated rim.

The frame should be of the best pressed steel. Semi-elliptic springs in front and ¾ in rear. Shock-absorbers should be used.

A 30-gallon gasoline tank should be carried in the rear. The gas should be delivered to a Rayfield carbureter under pressure.

The tires should be guaranteed and should be 36x4½ inches. Dorian rims should be used. The wheel base should be 124 inches.

There should be four large brakes each 17 inches in diameter and with easy adjustments.

The body should be of torpedo design, seating five people. The driver should be able to get in from right side. There should not be any door on left side in the rear. The seats should be very low and slanted a trifle.

The equipment should include a caravan top of light color, an automatic windshield built for the car, and the Gray & Davis lighting system. The Warner speedometer should be used, and with the clock built so as to be flush with the dash. Tires should be carried under rear seat and under front seat should be drawers for tools. There should be trunks running the entire length of the running boards. A compressed air self-starter, Klaxon combination horn, tools, foot rails, jack, etc., should also be included in the equipment.

This car should weigh about 3,200 pounds, and should cost about $3,000.

J. D. Crary, Jr.

Brooklyn, N. Y.

Illustrates Rotary Sleeve

Editor The Automobile:

While others are telling how they would have their ideal car built, I am going to ask for space in your valuable paper to show how I would build the engine, the all-important part of the car.

Of course it will not have poppet valves, as that would not be the latest fashion, so I have selected the rotary sleeve valve and I trust my ideas will be made plain by the accompanying sketches (Figs. 1 and 2).

The sleeve valve is hollow and has parts which uncover portholes in the cylinder wall at the proper time to admit the gas and let out the exhaust; the sleeve also has a number of small holes clustered together at the place where it is joined by the intake and exhaust pipes to admit the gas in intake sleeve and to admit the exhaust gases from the exhaust sleeve into exhaust pipe.

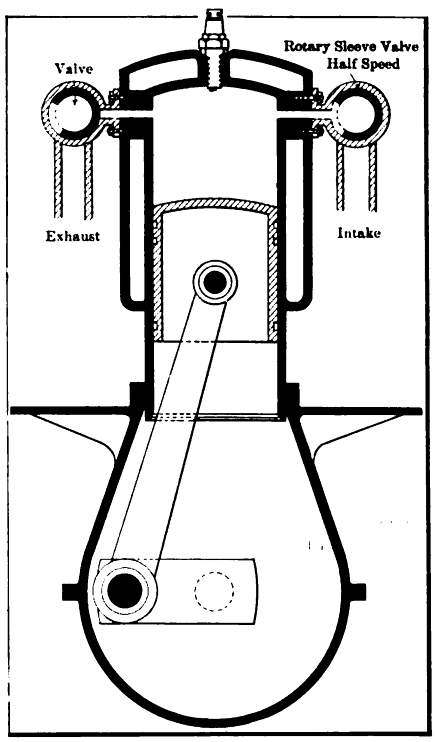

Fig. 1—Section through cylinder with rotary valve

The sleeve valves are operated by silent chain and sprocket or gears direct from crank shaft at one-half the speed of crank shaft. They are taper fit within the casings, run on ball and thrust bearings and are adjustable so that a proper fit can always be made, allowing for heat influences and wear.

This sleeve valve is adaptable to any number of cylinders, is easy to cast and machine; the valve parts being made separate and complete. Cylinders are easy to cast and all the parts are right out where you can get at them and put your hands on them. The pistons can go up in cylinders far enough to cover ports when explosion takes place to relieve shock against sleeve valves. The engine is easy to lubricate, easy to repair and will never leak or need grinding. Exhaust can be water-jacketed if necessary. It does away with a great many parts, complication and noise.

H. Lee Clark.

Canton, Pa.

What a Canadian Wants

Editor The Automobile:

The car should have a four-cylinder T-head motor with a 5-inch bore and a 6-inch stroke, the cylinders being cast in pairs. The valves should be on opposite side of the motor, be interchangeable, and have a diameter of 2¾ inches and enclosed in dust-proof covers.

The ignition should be furnished from a magneto and storage battery with a double distributor, firing two sets of plugs simultaneously on either battery or magneto.

The carbureter should be of the float-feed automatic type with 2-inch mixing chamber, hot water jacketed, a needle valve adjustment provided so as to be controlled from the dash. The clutch should be of the multiple disc type running in oil bath.

The transmission should be of the selective type giving four speeds forward and one reverse, direct drive being on fourth speed. The engine, clutch and gears should comprise a single unit power plant, and should be suspended from three points in the main frame.

It would be desirable to equip the car with a 124-inch wheelbase. The front springs should be 40 inches long and of the semi-elliptic type, and the rear springs 48 inches long of the three-quarter scroll elliptic type.

Tires of 38 x 4½ inches in size should be supplied, fitted to demountable rims, on both front and rear wheels. I prefer a car with right-hand drive, with the gear-shifting lever on the inside of the fore-door. There should be two pedals, the left to disengage the clutch and operate the service brake, the right to take the place of the emergency brake lever; both brakes should operate on the rear hubs. This arrangement would be more convenient and safer, as there would be no need for reaching for emergency brake lever.

The body of the car should be of aluminum where possible and of the straight-line fore-door five-passenger phaeton type, with low-set seats, having high backs and deep upholstery. This type is very comfortable combined with the long wheel base, large wheels and easy-riding springs.

The engine with large valves, ample size carbureter, and positive ignition system would give the car great power.

The equipment should include mohair top, windshield, two additional demountable rims, self-starter, speedometer.

Such a car as I have outlined should sell for about $3,500.

RUPERT S. HAMLIN.

Ottawa, Canada.

Wants Worm Drive

Editor THE AUTOMOBILE:

My ideal automobile is as follows: The wheelbase should be 115 inches, with wheels capable of taking a 36x4-inch tire and with Q. D. rims. The tire pump should be a part of the engine apparatus.

My choice of a motor would be one with rotary or sleeve valves; it would have four cylinders of 4¼-inch bore and 5-inch stroke. The cylinders should be cast in pairs, giving a three-bearing crankshaft. The crankshaft bearings should be of the plain type.

The clutch should be of the multiple-disc type and should be used in connection with a gearset of three speeds: 12, 7 and 4 to 1. The emergency brake should first disengage the clutch and then take up on the drums. The gearset should be located near the clutch and flywheel.

The propeller shaft should be encased in a torque tube and have a worm and gear drive to the rear axle. This would allow the propeller shaft to be aligned with the crankshaft.

The engine base should have hand holes and cover plates for easy examination of the connecting rod bearings, etc. The base should also contain a circulating splash oiling system.

I would specify a magneto for ignition while running and a dry battery set for use

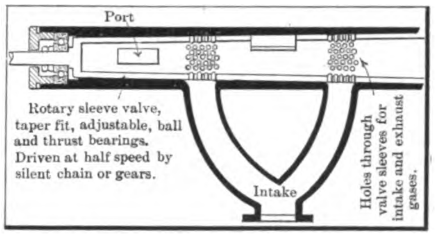

Fig. 2—View of the rotary valve suggested by a reader

in starting. The engine should be self-starting and fitted to the body best suited to the requirements of the owner. This outfit should cost from $1,200 to $1,400.

G. P. McGRAW.

Pierson, Iowa.

Requires Heavy Engine

Editor THE AUTOMOBILE:

The engine should have four cylinders of the L-type cast in pairs, they should be provided with removable cover plates over the water jackets to allow of cleaning. The motor should have a bore of 5 1-2 inches and a stroke of 7 1-2 inches with 2 3-4 inch valves.

The valves should be enclosed so as to exclude grit. This construction will give a full 48.4 horsepower A. L. A. M. and would doubtless develop 60 horsepower on the brake test.

I would specify an offset crank case split in half with side opposite camshaft removable to allow access to and the removal of the crankshaft, connecting rods or pistons whenever necessary without having to take down the engine.

The lubrication should be by positive force feed, by a gear-driven pump to all bearings and splash to connecting rods and pistons, oil contained in tank at side of engine with sight feed on dash.

Ignition should be by two independent Bosch magnetos, with two sets of Bosch spark plugs over valves.

The cooling system should consist of honeycomb radiator with gear-driven fan and water pump.

Selective type of transmission should be used with four speeds forward and reverse, running on large ball bearings with direct drive on third speed and geared 2 1-2 to 1 on direct.

The large diameter multiple disc clutch should be mounted on ball-bearing running in oil with six tension springs equidistant apart to allow taking up of wear.

Drive should be through shaft fitted with two universal joints, and be packed in grease to differential with a torsion rod alongside, and from differential to rear wheels through live axle. Both differential and live axle ought to run on Timken roller bearings.

The front axle should be of I-beam pressed steel, and a full-floating rear axle ought to be installed.

The exhaust should have two systems consisting of an ordinary muffler, and a set of pipes with a cut-out coming through the side of the hood.

Wheels should be 38 inches, of wire construction on Timken roller bearings. These should be shod with 5 1-2-inch tires. All wheels should be fitted with quick-demountable rims.

There should be four large brakes (about 17 x 3 inches) on the rear wheels, two internal, and two external.

The wheelbase should be about 135 inches.

Semi-elliptic springs in front and three-quarter elliptic in rear should be used together with shock-absorbers.

Steering should be by worm-and-sector gear, irreversible type with 19-inch wheel on a 2-inch post.

The equipment should consist of full torpedo type body seating two persons. A 40-gallon gas tank should be mounted at rear of seat with a large opening for filling. A top, Warner Autometer Clock and two extra rims with tires should be carried on the car.

A combination Klaxon horn, engine driven tire pump, jack, complete set of tools, and a self-starter should be installed on the car.

The car should be built of the very best material obtainable. The body should be built low with seats on the floor and tilted, and upholstered with smooth leather. Such a car would cost $4,500 or thereabouts.

A. S. P. O. R. T.

German Valley, N. J.

Raises New Point

Editor THE AUTOMOBILE:

In my opinion the matter of price in buying a car clashes with the ideal car that the purchaser would specify in the majority of cases, for the simple reason that in buying a cheap or medium-priced car the one who is buying the car generally wishes he could afford to buy a dearer and more refined product.

When stating this opinion I do not mean to say by any means that the cheaper cars are not good; but in making any purchase, whether it be automobile or roller skates, one expects more either in beauty of finish or in mechanical refinements when a higher price is paid than otherwise. The lower and medium-priced cars are far in the majority and it is perfectly natural that it should be so when it is considered that the wealthy class are in the minority and that the majority of automobile owners are people who are in merely what is known as fairly comfortable circumstances.

For the reasons that I have given I cannot agree with INTERESTED in his communication in the issue of October 5, when he states that cheapness is a factor in the ideal car.

LOUIS BOURGEOTTE.

New York City.

Little Bits of Motor Wisdom

Pertinent Pointers of Interest to Repairman and Driver

CARE OF TIRES ON THE ROAD—Care of the tires should not be confined to the time when the car is stationary in the garage before starting on a trip, but should also be a matter which will take the attention of the driver while he is on the road; especially if the trip be one of length. An inspection of the tires is generally made by the driver before he starts on a trip. This inspection should not be confined merely to the search for cuts, but also for spots which give evidence of an impending blow-out. These are generally determined by a small bubble-like formation on the surface of the casing.

After having searched for cracks and cuts, these bubbles should be made an object in the search, as they are, if anything, more dangerous than are the cuts, for the cuts will allow water to soak through the casing and cause the fabric to rot, which will be a slow process. A bubble will indicate, on the other hand, that the spot at which it occurs is so much weaker than the rest of the tire that it cannot withstand the pressure of the air within the inner tube sufficiently to hold its proper shape. If these weaknesses are discovered within the shop before the car starts upon the trip it would naturally be the duty of the careful driver, who abhors roadside accidents, to restore the casing to its original strength by cutting and vulcanizing. It will often be the case that the driver is not sufficiently acquainted with the process of vulcanizing to attempt the work himself, so that it will naturally have to be handed over to a repair shop, the work of repairing a blister on the casing being a much more complicated undertaking than the repair of a simple cut.

The inspection of the tire in the shop will disclose the weaknesses which have already progressed far enough to evidence themselves, but the others which are not in so advanced a state will remain hidden; it is these cases and the others which are the result of accident which make the occasional roadside inspection a necessity.

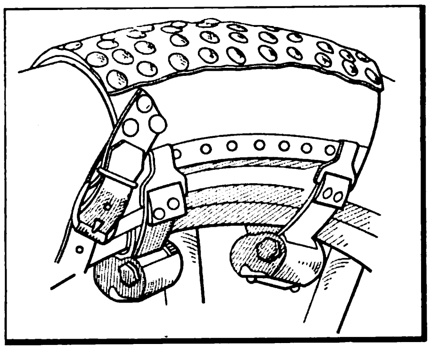

Fig. 1—Showing a tire boot or gaiter

Vulcanizing cannot, of course, be well carried on while the car is standing out on some country road, for the simple reason that the necessities are not as a rule at hand, so that other means will have to be found to either restore the tire to its strength temporarily or to eliminate the chances of a blow-out in another way. The spare rim is the medium through which many meet the exigencies of the occasion, while others, who have, perhaps, used their spare rim, employ the tire boots shown in Fig. 1.

These tire boots are very easily attached and will strengthen the shoe sufficiently to hold it against the impending blow-out until a place can be reached where the permanent repair may be made. In attaching the tire boot it should be very firmly strapped to the tire and then also fastened so that it will be impossible for it to slide longitudinally. There are generally straps fitted to the boot for all these purposes, and the only thing remaining for the driver to do is to tighten them sufficiently. If the boots are firmly fitted their usefulness is increased immeasurably and the possibilities of accidents in spite of the boots are greatly decreased.

MAKING ELECTRIC CONNECTIONS—It will often be found that a poor connection exists when the ignition of the motor is faulty. In making the new connection it should not be done hurriedly even if this minor repair is taking place somewhere along the road. It is easy to forget that a poor connection was made and the trouble will be sure to evidence itself again in a most uncomfortable manner. If the driver is fortunate enough to have detected the trouble without a long search he should be willing to sacrifice the small amount of time necessary to make the repair as it should be made.

The first three steps are depicted in Fig. 2. A pocket knife is used for the purpose of cutting off the outer insulation for about 1¼ inches along each piece of wire to be connected; the remaining insulation is then burnt off by holding a match beneath the wire. After the insulation has been thoroughly removed the knife is again called into action and the wire scraped so that a good connection will not be hindered by dirty wire. The wire will probably be of several strands, and in this case should be twisted between the thumb and forefinger, in the same manner as a mustache is twirled, so that the various strands will not separate from each other during the time that the connection is being made.

The ends of the wires are then laid together in the manner depicted at C in Fig. 2 and twisted over each other as shown. When they are twisted so that the length of the wires in contact is about an inch, the connections should be soldered as illustrated at E in Fig. 3. The joint is then ready to be bound with tape as shown at F. A careful joint such as this will

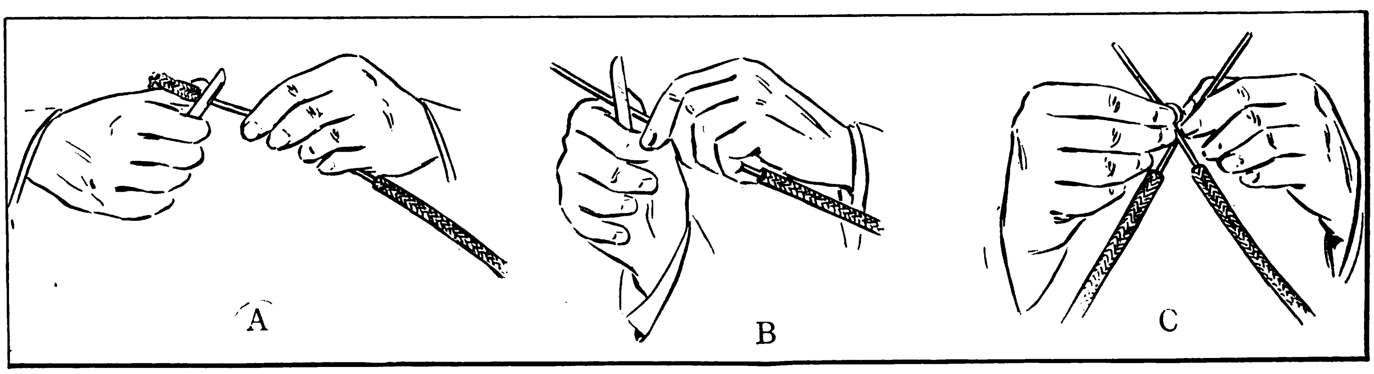

Fig. 2—Illustrating the first three operations in making a careful electric connection

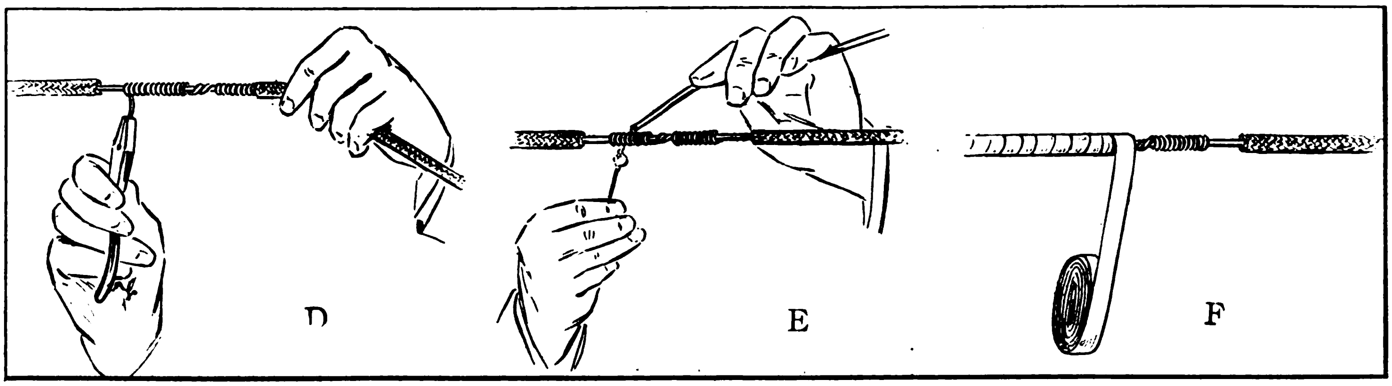

Fig. 3—Depicting the last three operations in making a connection in the wiring

not require much more time than when made carelessly. The difficulties rising from faulty connections are many and are often very hard to detect, especially if they are at the binding posts. The ordinary manner of connecting the wires at the binding posts is merely to form a sort of hook with the end of the wire, place it about the post and then screw the knurled nut down upon it. After a period of vibration the nut will often become loose and since the hook at the end of the wire has nothing left to support it it will leave the binding post and cut off the current. In most cases a casual inspection of the wiring will disclose what has happened, but in other cases the vibrations of the car bring the wire into intermittent contact with the other member of the circuit and the driver is at his wits' end to determine the seat of trouble.

Inspect Universal Joints—The universal joints are often neglected because they are not located where they are a constant reminder to the proprietor of the car, but it is very necessary, if the car is to be maintained in the best possible condition, that they have an occasional inspection. A good rule in the case of a car which is used moderately is to make this a monthly task. It is not necessary always to thoroughly clean these bearings every month, but they should at least have the supply of oil renewed. If this is done every month and the old oil cleaned out by flushing with kerosene before the new oil is put in they should never give any trouble.

There is generally a plug in the housing which can be removed for the purpose of flushing and refilling. When the plug is removed the motor should be turned over slowly while the kerosene is in the casing so that it will be thoroughly flushed out. Cotton waste should not be permitted within the casing as it will be sure to become caught in some irregularity of the metal and be twined about the bearing after the shaft is in motion.

The grease is generally inserted into the housings by means of a grease gun in the case of the rear universal joint, where graphite grease should be used. The front universal joint casing may be filled with transmission oil, or, when the weather is cold, cylinder oil may be used to good advantage. In some of the front universal joint casings a level cock is used and when this fitting is employed the oil should be put in up to the level of the cock. When filling, the cock is left open and oil is poured in until there is a flow from this cock, whereupon the cock is shut off and the casing cover replaced and fitted tightly so that the oil which is thrown about by the whirling shafts will not leak from the casing. In most cases the opening for the insertion of grease is merely sealed by a plug.

A very good practice is to lubricate and clean the wheel bearings, differential and gearset at the same time that the two universal joints are attended to, so that the whole work may be done at once with a saving of labor and material.

Extracting a Pin—There are numerous clever kinks which suggest themselves to those who are mechanically inclined and remarkable cases of ingenuity are frequently discovered among those who have had but little practical experience in the shop. On the other hand, however, little problems will present themselves which, it would seem, should not present the slightest difficulty to the merest child in the mechanical arts. A riveted pin will sometimes defy the misdirected efforts to remove it for a long time and the idea of using the vise to remove it may not occur to the mechanic until he has tried several other ineffectual schemes. The piece may be laid across the jaws of the vise as shown in Fig. 4 and be very easily hammered out by the aid of a punch. In case the end of the pin is riveted over, the end will have to be filed as a rule, although when riveted lightly the burred edge will oppose little resistance to a few light blows of the hammer.

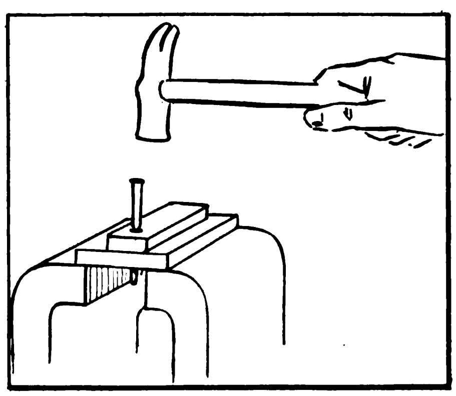

Fig. 4—Method of driving out riveted pin

In case the parts to be disassembled are delicate a block of wood should be inserted between each jaw and the metal so that no damage can be given by the edge of the vise. The punch in this case should be carefully laid upon the pin before being hammered so that it will not be liable to slip off and inflict a gash in the part.

Rapid Demagnetization Required—The core of the primary winding must be of such material that it permits itself to be readily demagnetized when the current passing through the solenoid is cut off. Soft iron possesses the quality of rapid demagnetization to a marked degree and is for that reason universally employed. The diameter of the coil is generally about 3/4 inch and about this there is a winding of some sort of insulating material which separates it from the primary winding.

It has been discovered that the rapidity of demagnetization will be markedly increased if the core is not made of a solid bar of iron but consists of a bundle of soft iron wires about 6 or 7 inches long. This is the customary method of manufacturing the core of the primary coils for use in automobile work where a rapid action of the trembler is required.

Calculating Clearance in Per Cent.—Let Volume of clearance = 13.73 cu. in.

Volume of clearance piston displacement = 44.51.

$$\% \text{ clearance} = \frac{13.73}{13.73 + 44.51} = 23.6$$

This idea will, of course, obtain for any size of motor. All that has to be done is to substitute the right values for those given and then work to the formula.

My Best Repair

Broken Studs

I ONCE had the misfortune to break a stud that united the manifold to the cylinders. It snapped off close to the cylinder casting, so that it was impossible to file a flat on it or turn it out with a pair of pliers. There was no repairer to whom I could go to have it fixed for several miles around and the noise of the exhaust leaking through was very disconcerting.

I stopped at a village blacksmith and obtained the loan of a drill, which, to say the least, was very primitive. None of the drills that he had would go anywhere near the stud, and I did not wish to spoil the thread, as I had no means of cutting another and did not know the thickness of the water jacket.

Consequently I persuaded him to make me a fine drill out of a piece of steel, which I filed down so as to obtain a cutting edge.

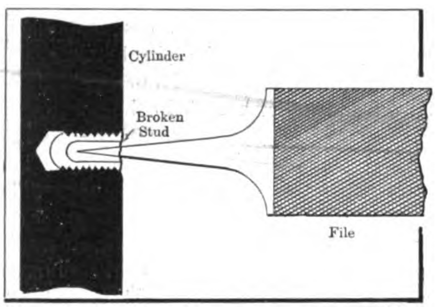

Fig. 1—Method of extracting a broken stud holding the manifold to the cylinders by drilling a hole and using a file

With the aid of the drill I made a small hole in the stud and tapped the tag end of a file in the hole with a hammer, in the manner shown in the illustration, Fig. 1.

Then it was simplicity itself to remove the part. I found it necessary to grind the tag end of the file slightly so as to obtain a good purchase in the hole. Since then I always carry a small drill in my kit and have found it very useful on many occasions. An example of this was given once when I broke a split pin in a shaft over which passed a castellated nut, and after fiddling with pin punches for some time the drill removed the pin in a second.

Montclair, N. J. R. F. C.

Cracked Intake Manifold

For some unaccountable reason the aluminum intake manifold of my motor cracked and though the motor did not stop altogether it lost a lot of power and caused me considerable annoyance. I traced every wire in the ignition system, although I was positive the plugs fired properly, took the carburetor to pieces without disturbing the

Temporary automobile repairs made by the driver or owner while on the road and permanent repairs made in the garage after the run is over, are interesting to all automobile owners.

It may be a spring leaf has broken; a shackle bolt or strap may break; a steering tie rod is bent; the car skids into a curb and bends a steering arm or the starting crank; a throttle or magneto connection breaks owing to vibration; a radiator leak is started by a stone or some other means; a leak in the gasoline tank is discovered; there is a small hole in the gasoline feed line; a brake facing may burn out; a brake connection breaks; a front axle gets slightly sprung; a clutch starts slipping, or any one of a thousand things may happen.

Every automobile owner is interested in knowing how repairs have been made, how long it took to make them, how much they cost, and by whom they were made.

We want you to write in simple language in a letter what repair of this nature you have had to make, how you made it, how long it took you and how much it cost.

You can make with your lead pencil one or two rough sketches indicating the broken or damaged part and showing how the repair was made.

The experience of each reader is interesting to every other reader. Analyze your past experiences and send in one or two of them.

Give your name and address, legibly written. If you do not want your name to appear, make use of a nome de plume.

Editor THE AUTOMOBILE.

manifold and looked at all the valves.

Thinking that the connection of the manifold to the cylinders might be faulty, the gaskets having given out, I took the manifold off and found a decided crack on the side near the motor and consequently out of sight when in the car. Here was my trouble, as by the process of elimination it could be nothing else. I obtained some putty at a hardware store and with the aid of a little insulation tape I bound the fracture around so as to prevent the air from being sucked into the manifold. I cannot describe the difference in the car's running. From sluggish it became vivacious in starting, and would hold on to hills on top speed where before I had been compelled to change.

It is my impression that instead of discarding the manifold as faulty at the factory the makers, or rather some slipshod workman, painted a little shellac over the crack and let it go at that. I took the pipe as soon as I could conveniently spare the car for a few hours and had it welded while I waited. I took the opportunity to have a pair of webs welded on so as to form a support for the carbureter. It is a wonder to me that makers do not support the carbureter by a stay from the base chamber. J. D. R.

OIL CITY, PA.

Leather Contacts — Clutch Slips

The troubles that motorists sometimes have on the road are not always the fault of the maker, but are sometimes due to carelessness of his employees. My case was of the latter variety. The clutch on my car is of the leather cone type and I do not want anything better. I took my new purchase over with pride and proceeded to drive it home, which was about 150 miles from New York. Everything went nicely for 70 or 80 miles when I noticed that she was not pulling so well on hills and the engine was slightly inclined to race.

I put it down to a new leather that had not worked in, so I purchased some fuller's earth at a drug store, and sprinkled a little on the leather. Matters improved somewhat for a few miles, but the trouble again manifested itself. I then washed it with some kerosene to expand the leather and

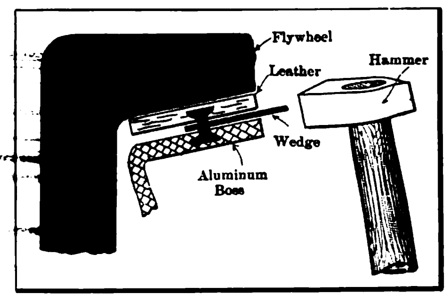

Fig. 3—Forcing a wedge between the aluminum boss and the leather of the clutch to expand the latter, and prevent slipping

afterward with a little gasoline to wash off any dirt that may have been there.

Things had got to that pitch that it was almost impossible to get along at all. I first thought that the floorboards prevented the pedal from coming back far enough, but this was not so.

I then came to the conclusion that it was either a matter of taking the clutch down or faking it to get home. I took the latter idea as being the quickest. I obtained a pair of snips and a piece of tin and cut some short pieces and drove them between the aluminum boss and the leather between the rivets with a hammer in the manner shown in the sketch, Fig. 3. It worked admirably and I got home without any further trouble. I found that the bolts securing the flywheel to the crankshaft boss had been left too long and after the leather had settled, so to speak, these bolts prevented the metal boss of the clutch from sliding in far enough to allow the leather to contact with the flywheel. This I remedied by reversing the bolts, which I found was the correct way for them to be.

KALAMAZOO, MICH. H. P. M.

Modern Road Building Enterprises

FLINT, MICH., Oct. 14—The county road commissioners of this county have been allowed an appropriation which will amount to about $43,500 to be spent next year.

RICHMOND, VA., Oct. 14—The Peninsular Automobile Association has raised $5,000 toward the improvement of the road between Newport News and Richmond, and Richmond has raised $2,500. A larger sum will no doubt be raised and the work continued.

BALTIMORE, MD., Oct. 16—All objections have been removed and the boulevard between Annapolis and Baltimore will now be constructed as rapidly as the work can be pushed through.

OKLAHOMA CITY, OKLA., Oct. 12—About the last week in November there will be a vote taken on the $1,250,000 in bonds to construct the first group of hard surface roads in the State. The plans call for 155 miles of asphalt and 21 miles of crushed stone.

DETROIT, MICH., Oct. 14—A good roads meeting will be held in Monroe on October 17, for the purpose of furthering the original route of the Detroit-Toledo highway. There are rumors that it is proposed to make use of highways which have already been constructed in neighboring towns and thus escape Monroe altogether.

COLUMBUS, O., Oct. 14—At the annual meeting of the Ohio Good Roads Federation it was decided to inaugurate a vigorous campaign to secure a constitutional amendment permitting the issue of bonds for the improvement and construction of State roads.

PHILADELPHIA, PA., Oct. 13—At the recent annual meeting of the Quaker City Motor Club, nominations of officers and members of the board of governors were made for the ensuing year. The nominations created a lively interest as the list of nominees outnumbered the list of vacant offices about five to one.

TOLEDO, O., Oct. 14—Splendid progress is being made by the promoters of the new automobile club for owners of machines in Toledo. It is now certain that a full-fledged organization will be in existence in a very short time.

Adapting the Motor to Farm Uses

(Continued from page 675)

manlike fashion and turning under the stubble and the fertilizers or manure spread on the surface. While the driving wheel tracks in the furrow which the disk is just then forming the right front wheel tracks in the furrow previously made, and this provision, bringing both wheels in the hollow, with the crest between them, prevents the skidding which might otherwise result from the oblique pressure of the disk. The driving wheel has two concentric rims of different widths, so disposed that the wider and smaller rim bears against the untouched soil while the larger and narrower rim follows the bottom of the furrow. On the road only the latter is in action. The small and broad rim is provided with traction ribs which may be either fixed or subject to adjustment.

In the Linard-Hubert motor plough Fig. 4 *a socs percutants* ("with shares that strike") the motor chassis is equipped with a four-cylinder, 20-horsepower motor turning at 400 revolutions per minute, and the plough chassis consists of a simple frame which is mounted at the rear of the motor chassis and from which the plough shares are suspended. By a special mechanism the motor imparts intermittent impulsion into the soil to the shares, actuating them successively, and as the velocity of the impulsions is greatly superior to that of the vehicle's advancement over the soil, the traction of the vehicle is influenced by the work only for brief periods, and the work can go on even if the ground adhesion is imperfect. When the shares are dismounted, the frame of this cultivator plough may be used for many other purposes.—From *Bulletin Official,* August.

GRAND RAPIDS, WIS., Oct. 14—The Grand Rapids Commercial Club has decided to abandon the proposition of bringing the Crowe Motor Car Company, of Detroit, to this city.

SYRACUSE, N. Y., Oct. 14—As the result of a special recruiting campaign the membership of the Automobile Club of Syracuse has increased to 850.

Calendar of Coming Events

Shows

Oct. 7-14..........Chicago, Ill., Show of Chicago Automobile Trade Association.
Jan. 2-11..........New York City, Hotel Astor, Importers' Salon.
Jan. 6-13..........New York City, Madison Square Garden, Twelfth Annual Show, Pleasure Car Division, Automobile Board of Trade.
Jan. 6-20..........New York City, Madison Square Garden, Annual Show, Motor and Accessory Manufacturers.
Jan. 10-17.........New York City, Grand Central Palace, Twelfth Annual Show, National Association of Automobile Manufacturers; also Motor and Accessory Manufacturers.
Jan. 15-20.........New York City, Madison Square Garden, Twelfth Annual Show, Commercial Division, Automobile Board of Trade.
Jan. 22-28.........Providence, R. I., Providence State Armory, Rhode Island Licensed Automobile Dealers' Association, Automobile and Accessories Show.
Feb. 17-24.........Minneapolis, Minn., National Guard Armory and Coliseum, Annual Automobile Show, Minneapolis Automobile Show Association.
Jan. 27-Feb. 10....Chicago Coliseum, Eleventh Annual Automobile Show under the auspices of the National Association of Automobile Manufacturers. Pleasure cars, first week. Commercial vehicles, second week.
Feb. 14-17.........Grand Rapids, Mich., Third Annual Show.
Feb. 19-24.........Hartford, Conn., Annual Show, Automobile Club of Hartford, State Armory.
Week Feb. 22.....Cincinnati, O., Annual Show, Cincinnati Automobile Dealers' Association.
March 2-9.........Boston, Mass., Tenth Annual Show, Boston Automobile Dealers' Association, Inc.

Meetings, Etc.

Nov. 20-24........Richmond, Va., First American Road Congress, under auspices of American Association for Highway Improvement.
Nov. 22...........Road Users' Day, under direction of Touring Club of America.
Jan. 18-20.........New York City, Annual Meeting of the Society of Automobile Engineers.

Race Meets, Hill-Climbs, Etc.

Oct. 9-13..........Denver, Colo., Reliability Run, Denver Motor Club.
Oct. 11-18.........San Francisco, Cal., Reliability Run, Good Roads Assn. of Northern California.
Oct. 13-14.........Peoria, Ill., Track Races, Peoria National Implement and Vehicle Show.
Oct. 14...........Santa Monica, Cal., Road Races.
Oct. 14 (to 26)....New York City, Start of the Annual Glidden Tour, en route for Jacksonville, Fla.
Oct. 30...........Minneapolis, Minn., Hill Climb.
Oct. 20-21.........Sioux City, Iowa, Track Races, Sioux City Automobile Club.
Oct. 21...........Atlanta, Ga., Track Races.
Oct. 21...........White Plains, N. Y., Track Races, Westchester Driving Club.
Oct. 21-22.........Los Angeles, Cal., Track Races, Motordrome.
Oct. 27-Nov. 3.....Chicago, Ill., Thousand-Mile Reliability Run, Chicago Motor Club.
Oct. 28............Newark, N. J., Reliability Run, Newark Motor Club.
Oct. 30............Harrisburg, Pa., Economy Run, Motor Club of Harrisburg.
Oct. 31............Shreveport, La., Track Races, Shreveport Automobile Club.
Nov. 2-4..........Philadelphia Reliability Run, Quaker City Motor Club.
Nov. 3-4..........Columbia, S. C., Track Races, Automobile Club of Columbia.
Nov. 4-6..........Los Angeles-Phoenix Road Race, Maricopa Auto Club.
Nov. 9............Phoenix, Ariz., Track Races, Maricopa Automobile Club.
Nov. 9, 10, 12.....San Antonio, Tex., Track Races, San Antonio Auto Club.
Nov. 27...........Savannah, Ga., Vanderbilt Cup Race, Savannah Automobile Club.
Nov. 30...........Los Angeles, Cal., Track Races, Motordrome.
Nov. 30...........Savannah, Ga., Grand Prize Race, Savannah Automobile Club.
Dec. 25-26.........Los Angeles, Cal., Track Races, Motordrome.
Nov. 3-11.........London, Eng., Olympia Show.

Foreign Fixtures

Oct. 12-22.........Berlin, International Automobile Exhibition.

Baggage Must Be Carried

WHAT would you think of a well-dressed young man living at one of the leading hotels in New York starting out on a Monday morning for the laundry with both coat pockets filled with collars, his pajamas under one arm, his soiled linen under the other arm, his hose in one hand and old handkerchiefs in the other hand? Such a sight would be an absurdity, yet many of our automobile tourists do this identical thing when it comes to going away in their cars for a tour of several days or perhaps a few weeks. The baggage is the bugbear with them; they tie part of it onto the back of the tonneau; they load all that they can into the tonneau until it is so full that the passengers have not room on the floor for their feet; they pile as much as they can onto the running board at the right side and on the left side; they put suitcases between the front fender and the hood on the right side and also on the left side; they put extra oil cans on the floor boards of the front seat; they tie suitcases onto the sides of the tonneau over the fenders; they put some of their surplus clothing under the rear seat cushion and some more of it on the coat rail at the back of the front seat; and with all this done they fill their overcoat pockets, stuff every little pocket in the car doors and fill every spare corner in the car.

It is not very pleasant making a tour in such a car. It might be all right for a short day, with the sun shining and the dust not too bad, but it would be most uncomfortable in a rain storm or on a cold day. The starting off of the Glidden tour was an object lesson in lack of preparedness in carrying baggage on a long tour. On other pages are illustrated the various means of transmuting a pleasure car into something little worse than a truck and little better than a gypsy van.

It was not always the fault of the tourist; part was his and part was also that of the maker of the car body. Car bodies are not well designed for carrying baggage on a tour. There is not enough room to carry baggage commensurate with the number of people traveling in the car. The car body is built to carry people but not to carry their baggage. This is not right. The body must be improved so that it will carry the baggage. What is the use of having a car to travel for weeks at a time but yet not be able to take the necessary baggage. To travel for one or more days or for one or more weeks a goodly amount of baggage must be taken along, and the car builder who fits a body which is entirely inadequate to care for such conditions is not meeting face to face one of the big problems of the car industry to-day.

The baggage-carrying factor must be wrestled with. It must be settled. It cannot be settled by the method described in the opening paragraph of this editorial. How absurd it is to spend hundreds of dollars imparting the finest possible finish to an automobile body and then hang baggage over every attainable part of the car. This is preposterous. A car should have adequate baggage-carrying possibilities and it is not impossible to make a body that has such. One solution is impressing the body designer of the fact that a car body is intended to carry a reasonable amount of baggage as well as a reasonable number of people.

One solution of the baggage-carrying scheme is to use such baggage accessories as are on the market, consisting, as they do, of trunks for the rear of the tonneau or neat cases for the running boards. No matter where the trunk is it should be of neat design and good finish. It is poor judgment to place a 5-cent trunk on a $100 car. The scheme of harmony should be carried out. Another solution is to study space economy in body design. The gasoline tank, in the majority of cars, occupies the entire space under the front seat. If pressure feed were used the tank can be placed under the chassis at the rear. One maker is placing the fuel tank under the center of the chassis at the right side where it is entirely concealed and where it is convenient for refilling. If the space under the front seat were left free it could be used for a score of things. The tools, which are usually carried under the rear seat, can be placed under the front one. These tools should be under the front seat, because, then, they can be obtained and put away again without disturbing everyone in the tonneau.

When the tools are located under the front seat the space beneath the rear seat should be utilized for carrying spare tires and suit cases. It seems folly to suggest carrying all here, but some foreign makers have solved this problem and are able to get two suitcases under the seat and carry two spare tires back of the tonneau. One maker has become still more economical and has designed his top to fold over this compartment. There is plenty of room in the rear of the tonneau for suitcases, tires and other small packages, but you cannot get them into such a space unless the body design is carried out accordingly. It is a question of designing and not an after-thought. When the tailor makes your overcoat he puts in the pockets. They are not added as needed after the coat has been worn half a season. The fact that you do not fill each pocket each time you put the coat on is not any reason why you should not have the pockets. The pockets are useful, they serve their purpose, and when needed they are needed.

So with an automobile, the baggage spaces are needed. You may not make any use of them in trips around town, but the first time you go away to spend a day or so they are very much in demand. Then there is a rallying to the hardware store for rope or leather straps to decorate the outside of the car with traveling necessaries. The 1912 body maker should meet this question face to face. If he cannot entirely solve it he should solve as much of it as he can. If you cannot have the whole, then furnish a part, at least. This work cannot be accomplished at once, it will take a few seasons, perhaps more.

In carrying baggage several points of value should be considered. A suitcase should be protected. As it is at present if the suitcase is carried outside of the body the dust finds its way into the interior, to the damage of all the clothing. If wet weather is encountered there is much damage due to dampness. As it is at present when you go on a tour of several days you run a chance of ruining the car finish with the suitcase or spoiling the suitcase. Neither of these is economical. It should be possible to use a suitcase a few days on a car without injury. Extra tires have always been an eyesore on highly finished cars and should be removed from the side of the car. If the tires have to be carried on the side they should be encased in good covers and not left without any covering at all with the paper wrapping that was on when taken out of the tire depot.

The external appearance of the car has a moral effect on all who see it. When a car starts out loaded for a tour it should tend to excite the desire for touring in the minds of those who cannot go. A well-trimmed car, which looks a tourist in every respect, will do this; but a car with baggage scattered all over it will not attract but actually repel. It will help touring when cars are fitted with bodies built to carry baggage for tours. The very fact that care has been taken to provide such spaces impresses the car owner with the fact that the car is intended for touring. As it is to-day the owner simply thinks of his car as an around-town vehicle and not a cross-country one. The car owners can assist in this work by taking it up with the makers.

Shows Engross Attention

New York City, Oct. 17—Applications for exhibition space at the coming show of the N. A. A. M. at the New Grand Central Palace continue to be received. The show will be held January 10-17 and will no doubt be a great success, as the space remaining is rapidly being decreased. Among the latest applicants are the Decatur Motor Truck Company, Universal Motor Truck Company, Atterbury Motor Car Company, Velie Motor Car Company, Koehler Company, Bergdoll Company, Metz Motor Car Company, Westcott Motor Car Company, King Motor Company, Bushnell Press Company and the Atlantic Motor Truck Company.

Chicago Show Successful

Chicago, Oct. 16—The Fall show of the Chicago Automobile Trade Association, which came to an end Saturday night, was a success far greater than anticipated by its promoters at the beginning of the week. Favored by Indian Summer on all but the last day, the turnout of the prospects was surprising and as a result many of the dealers down the row actually made sales that were not anticipated. The country dealers, too, took a great interest in the affair and some of the large branches like Ford, Buick, Studebaker, Hupmobile and Overland had their agents come in and look over the 1912 models.

There only was one feature that slipped a cog. That was the trackless trolley, made up of demonstrating cars which were supposed to carry spectators up and down the row. The idea was all right in theory but apparently did not work out well, the people being puzzled as to how to get tickets. Joy riders took advantage of the opportunity to a certain extent and toward the latter end of the week some of the dealers pulled their cars out of the line and controlled them themselves. However, the fundamental idea seems all right and doubtless another year the details can be worked out better and the trackless trolley made really useful.

Outside of the Chicago fire celebration on Monday, the feature of the week was the truck parade which was held Friday night. The parade was organized at a day's notice but despite this there were more than 200 vehicles in line, the majority of which were furnished by the big mercantile houses of Chicago, which took a great interest in the turnout. The show was put on with the object of stimulating trade at this particular season, and, judging from the numbers who attended the salesrooms during the week, it was a big success.

New Sanctions Granted

New York City, Oct. 17—A telegraphic application for a sanction covering a tour from Denver to New York has been received by the contest board of the A. A. A. It will probably be granted at an early date according to advices here. The matter has been turned over to Ralph W. Smith, of Denver, Colo., who is one of the twelve members of the contest board, and will be decided by him.

Part of the route between these two cities was covered in the Glidden tour of 1909 and there is no reason why the tour should not prove a success since conditions are very good for intermediary points. The date of the tour is from October 26 to November 7. The tour will be held by the Denver Chamber of Commerce.

Sanction has been granted for a series of races to be held over the Los Angeles motordrome on October 21 and 22. There are a number of cars which entered in the Santa Monica race which will participate in the events. The race is held under the auspices of the Los Angeles Motor Dealers' Association.

Kansas City at Peace

Kansas City, Mo., Oct. 16—Special telegram—Kansas City automobile dealers have at last consolidated. After 2 years of wrangling, dealers of both organizations met here to-night and formed a new association which they named the Kansas City Motor Car Dealers' Association. This is the culmination of the bitterest fight ever known in the motor world. Two shows a year have been held and thousands of dollars have been spent by the dealers of each association to outdo the other; many attempts have been made to consolidate both associations but up until to-night they have met with defeat. By unanimous vote one big automobile show was decided upon, the date being set immediately after the Chicago show.

The following officers were elected: J. Frank Witwer, of the Witwer Motor Car Company, president; W. E. Mallory, of the Jackson Motor Company, vice-president; R. C. Greenlease, of the Greenlease Motor Car Company, secretary; and H. G. Kirkland, of the Overland Company, treasurer. The show committee follows: T. S. Dey, Geo. A. Bond, C. B. Riggs, S. F. Scott and E. S. Hunnewell.

This amicable solution of the situation is a most desirable one as the different dealers and branches, as well as the industry, have suffered because of the unnecessary rivalry during the last couple of years.

Saurer-Mack Combine Completed

NEW YORK, Oct. 18—The uniting of the Mack and Saurer truck interests, which was announced in these pages some weeks ago, has been perfected, the new organization, an incorporation of Delaware, being known as the International Motor Company, with a capital of $10,000,000. This new incorporation will have its head offices at 30 Church street, New York City, and will have the entire management and supervision of The Mack Bros. Motor Car Company, Allentown, Pa., and the Saurer Motor Truck Company, Plainfield, N. J. The manufacture of Mack and Saurer trucks will be carried on at these respective plants, the factories being conducted as distinct organizations. It is expected that the output for the coming year will be approximately 2,000 trucks of different types and load capacities. The present sales branches of both Mack and Saurer will become the branches and agencies of the International Motor Company, which organization will conduct in all of the principal cities service stations for both makes of trucks. These stations will include inspection and maintenance systems.

Officers and directors of the International Motor Company are: President, C. B. Coleman; Chairman of the Board, W. D. Sargent; Vice-President, J. M. Mack; Treasurer, S. C. Richardson; Secretary, Vernon Monroe. Directors are: Otis H. Cutler, President American Car & Foundry Co.; Benjamin Story, Jr., Vice-President of the Bankers Trust Co.; Arthur H. Lockett, Pomroy Bros., bankers; Hunter Marston, Blair & Co., bankers; Charles H. Sabin, Vice-President Guarantee Trust Co.; George B. Case, of White & Case, attorneys; William G. Pearce, Vice-President American Brake Shoe & Foundry Co.; C. P. Coleman, President Saurer Motor Truck Co.; W. D. Sargent, President Reading Steel Castings Co.; Herbert H. Dean, Edward B. Smith & Co., bankers; John M. Mack, President Mack Bros. Motor Car Co.; Joseph S. Mack, Treasurer Mack Bros. Motor Car Co.; Montgomery Hare, attorney; Warren A. Wilbur, President E. B. Wilbur Trust Co.; Harry W. Davis, Secretary Delaware Trust Co.; Martin E. Kern, Vice-President Mack Bros. Motor Car Co. The general offices of the International Motor Car Company will be at 30 Church street, New York City.

Denver Electric Parade and Reliability

DENVER, COL., Oct. 14—The opening feature of the Second Annual Electric Show of the Colorado Electric Club, which opened here this evening, was a big parade of electric vehicles exclusively. Never before in America has there been such a parade and the enthusiasm it created augurs well for its adoption by electric clubs in many other sections of this country. It was an electric parade in every sense of the word, even the policemen, who cleared the way, rode in electric runabouts and the bands appeared in huge electric band wagons. Many of Denver's most prominent people entered their cars, many of which were beautifully decorated.

Handsome prizes were awarded to the first eight cars in the coupé and open runabout classes. Mrs. Charles A. Murnan's coupé, which was covered with a profusion of imitation mountain columbines, the heart of each one being a tiny incandescent light, won first place in its class. Mrs. W. P. Carstarphen, Jr., wife of W. P. Carstarphen, president of the Colorado Electric Club, presented the best open runabout. The body of the car was draped in white and poised in front of the driver was a large star outlined with electric lights.

DENVER, COLO., Oct. 17—Special Telegram—The winner of the 880-mile Denver reliability tour held here last week is still in doubt. A protest has been filed against the decision of the referee in awarding first place to the Flanders roadster, which was announced to-day as winner, with only 17 points against it. The Ford was awarded second, 19 points; and Cadillac, third, 23 points. The Ford protested the decision on the ground that the technical committee did not inspect the Flanders properly. The decision of the judges was delayed because of the thorough mechanical tests given the cars after finishing the tour and the final result now is delayed indefinitely because of the absence of the refere from the city. The twelve cars left Denver Monday, October 9, and returned Friday after covering 880 miles of prairie and mountain country in Colorado and Wyoming. The route covered fine selling districts and the excellent showing of the cars under the severe conditions means a great impetus to rural trade. The tourists were welcomed enthusiastically at all points, the run was a success in every way.

Car	Driver	Penalty
Flanders	L. M. Slater	17
Ford	William Thorney	19
Cadillac	Bert Hall	23
Ford	Fred Alkire	35
Regal	J. E. Barker	54
Everett	M. B. Fetcher	59
Flanders	Leroy Ward	74
Mitchell	A. J. Wilson	84
Reo	Jas. McDonald	103
Elmore	Geo. Williams	104
Maxwell	Geo. McIntosh	104
Buick	R. E. Young	Withdrawn

Wagner to Drive a Fiat

Louis Wagner, one-timer winner of the Vanderbilt cup and winner of the first American grand prize race, has been selected by the Fiat Company to drive a Fiat in the coming grand prize race in place of Felice Nazzaro, originally selected.

National Wins Santa Monica

(*Continued from page 661*)

The cylinder sizes of the different cars in the four different races are as follows, the order of cars being the same as in the tabulations given on pages 660 and 661. All cars were four-cylinder types:

Car	Driver	Bore (inches)	Stroke (inches)
National	Herrick	5	5 11-16
Marmon	Patschke	4 3-4	7
Marmon	Dawson	4 3-4	7
National	Merz	5	5 11-16
Pope	Dingley	4 3-4	5 1-2
Stutz	Lewis	4 3-4	5 1-2
Marmon	Keen	4 23-64	5
Marmon	J. Nikrent	4 23-64	5
Mercer	Hanshue	4 3-4	5
Buick	L. Nikrent	3 3-4	3 3-4
Ford	Charles	3 3-4	4
E-M-F	Seibel	4	4 1-2

The official times for the nine contestants in the small race for cars with motors under 23 cubic inches were received too late to appear in the general tabulation. This race had four contestants that finished, a Buick, a Ford, an E-M-F and a Flanders. The Buick, driven by Nikrent, traveled the 101 miles at an average speed of 59.20 miles per hour; the Ford at 57.21 miles per hour, and the E-M-F at 52.30 miles per hour. The total running time of the Buick was 103 minutes and 21.70 seconds; the Ford's time was 105 minutes 22.45 seconds, and the E-M-F time 115 minutes and 54.20 seconds. Soules, driving a Flanders, completed the race, but his time is not known; Hanshue, in a Reo, made 10 laps; Fleming, in a Locomobile, ran 10 laps; Dequelin, in a Sunset, made 8 laps; Anthony, in a Regal, traveled 5 laps, and Smith, in a Maxwell, 2 laps.

World's Records Broken at Peoria

PEORIA, ILL., Oct. 14—In concluding the two-day race at the Peoria track, held as one of the attractions at the National Implement and Vehicle Show, the Marmon Wasp and Hotchkiss Whirlwind lowered the Illinois State record for 5 miles on a 1-mile circular track very substantially. The former record, made on the Hawthorne track at Chicago, was 4:70 for the 5 miles. Heineman, driving the Wasp, made the five laps in 4:33 and Judy Kilpatrick, driving the Hotchkiss, lowered the Wasp's time by 1 second.

The only accident of the two-day meet came in the last lap of the last race on the final day of the meeting. The big Hotchkiss car, driven by Kilpatrick, was driven into the fence on the 1-4-mile turn by Raimey in his Cino. Neither driver nor car was badly injured.

On the first day of the meet, October 13, John Raimey, driving the Cino racer, set two world's records for a 1-mile, flat, circular track in the 10-mile, class E, non-stock race for cars of 300 cubic inches piston displacement and under, the feature of the opening day's motor race card at the National Vehicle and Implement Show here this afternoon. With a standing start he made the first lap in 1:03, a new world's record for cars of that size. He pulled down another world's mark when he completed the 10 miles in 9:56 2-5. He finished a winner by 3 seconds over a field of eight fast cars. Raimey also won a 5-mile, class C event, for cars of 231-300 cubic inches piston displacement.

In the time trials Judy Kilpatrick in his 200-horsepower Hotchkiss nosed out Heineman in the Marmon Wasp, negotiating the mile in :55 2-5. The Wasp was a second slower. Cino car finished third in :56 flat.

The summaries for both days are as follows:

SUMMARIES OCTOBER 14

Time Trials, 1 Mile

Car	Driver	Time
Hotchkiss	Kilpatrick	0:55 2-5
Marmon Wasp	Heineman	0:55 3-5
Cino	Raimey	0:56
Staver-Chicago	Monckmeier	1:00 1-5
Interstate	Fouts	1:01 2-5
Little Case Giant	Heineman	1:02

5-Mile, Class C, 231 to 300 Cubic Inches

Cino	Raimey	4:59 4-5
Staver-Chicago	Monckmeier	5:03 3-5
Little Case Giant	Heineman	5:03 4-5
Staver-Chicago	Knudson	5:08

2-Mile, Novelty, Australian Pursuit, Stock Cars

Staver-Chicago	Monckmeier	5:08 1-5
Case "6"	Jaggersberger	5:16

10-Mile, Class E, 300 Cubic Inches and Under

Cino	Raimey	9.56 2-5
Abbott-Detroit	Roberts	9:59
Staver-Chicago	Monckmeier	10:00 1-5
Staver-Chicago	Knudson	10:35

3-Mile, Class E, Handicap

Marmon Wasp	Heineman	3:04
Little Case Giant	Maxwell	3:20 2-5

10-Mile, Class C, 301 to 450 Cubic Inches

Velie	Stickney	10:38 1-5
Interstate	Fouts	11:24

SUMMARIES OCTOBER 14

Time Trial, 1 Mile

Marmon Wasp	Heineman	0:54 4-5
Cino	Raimey	0:56 3-5
Hotchkiss	Kilpatrick	0:57 1-5
Abbott-Detroit	Roberts	0:57 3-5
Velie	Stickney	1:00 3-5
Interstate	Walker	1:02 1-5
Little Case Giant	Heineman	1:02 4-5

Buick Match Race, 3 Miles

Minneapolis to Hold Hill Climb

MINNEAPOLIS, MINN., Oct. 15—Another change has been made in the date for the coming hill-climb and the sanction which was applied for last week affixes the time for Thursday, October 26, at 1:30 p.m. Arrangements have been completed and permission has been secured to hold the contest on the Columbia Heights hill leading off Central avenue. The hill is three miles long.

S. L. Stone, for the past three years assistant to J. B. Eccleston, sales manager of the Oakland Motor Car Company, Pontiac, Mich., has been transferred to Buffalo, where he becomes general manager of the Centaur Motor Company, of that city, dealers of Oakland cars in western New York and Pennsylvania.

The Newton-Humphreyville Company, Newark, N. J., were appointed Thomas dealers by Manager C. S. Henshaw, of the New York branch, the past week, and will handle that car in central New Jersey.

S.A.E. Visit is Gaining

NEW YORK, Oct. 18—Foreign manufacturers are manifesting an active interest in the intending visit of members of the Society of Automobile Engineers to Europe. Many of them have expressed a willingness to open their establishments to the inspection of the party which leaves New York November 1. The latest invitation is from the famous house of Lemoine, in Paris, which is perhaps the leading manufacturer of motor vehicle axles and forgings in Europe. The proprietors have asked the officials of the S. A. E. to include a visit to the plant and an inspection of the various processes of axle construction in the program during the stay of the members in Paris.

While in London the S. A. E. party will inspect the workings of one of the largest garages handling public service vehicles. This is of unusual present interest on account of the financial success of the great London motor bus and motor cab services which is attributable to efficient methods of garage management.

Detroit Building Operations Brisk

DETROIT, MICH., Oct. 16—As further evidence of the prosperous condition of the automobile industry, the Hudson company has broken ground for a large addition to its extensive plant on Jefferson avenue completed only a year ago; and two other companies, the Hupp Corporation and the Hupp Motor Car Co., will begin the erection of new fectory buildings in the immediate future.

The Hudson addition will connect with the east end of the present plant. It will be 530 feet long, 60 feet wide and two stories high, and will conform, in type of construction and in its external appearance, to the rest of the establishment. Steel and concrete are to be used almost exclusively in the construction. The extension will give the company 63,600 additional square feet of floor space. It is to be ready for occupancy by January 1.

The Hupp Corporation has awarded the contracts for its new factory building and power house at Lycaste street and the Michigan Central Railroad and work is to be rushed to have the structure finished in the minimum of time.

As a site for a complete new plant, the Hupp Motor Car Company has acquired 7 acres of land at Mount Elliott and Milwaukee avenues, adjacent to the new Belt Line Railway and opposite the plant of the Grabowsky Power Wagon Company. The purchase price is said to have been about $40,000. Plans are being prepared for a plant that will triple the capacity of the company's present factory, at Jefferson and Concord avenues. These quarters were outgrown several months ago and it was found necessary to lease other buildings.

Work is progressing so rapidly on the new Ford buildings, which will double the present capacity of the big plant, that they will be finished by December 1, fully a month earlier than time called for in the contracts, according to the present outlook. In this connection, it transpires that the John R. Kime mills, of Buffalo, which do most of the pressed steel work for the Ford company, and which are controlled by the latter, will be moved here when the extensions are completed. This information comes direct from Henry Ford, president of the company. "We are also putting in a new 5,000 horsepower gas engine to replace the 1,600 horsepower engine we are now using," said Mr. Ford to the representative of THE AUTOMOBILE. "We intend to produce our own gas for this engine."

Local car makers are greatly interested in the outcome of plans now under way for the establishment of a mammoth steel plant on a 50-acre site west of the city, on the River Rogue. The interests behind M. A. Hanna & Co., of Cleveland, are backing the project. The same interests control the Detroit Iron & Steel Co., which has a large plant on Zug island, in the Detroit river, for the production of steel in the raw state. The new plant, if the plans go through, will be operated in conjunction with the Zug island enterprise, taking over the raw steel and turning it out a finished product for all manufacturing purposes. The concern will be known as the Michigan Steel Co. and will be capitalized at $2,500,000. The Union Trust Co., of this city, and Peabody, Houghteling & Co., of Chicago, have agreed to underwrite the bonds that are to be issued. The establishment of a steel plant here would mean a great deal to the automobile industry of the town in the way of quicker deliveries. It would also mean a big saving in freight rates.

The organization of the new export bureau of the Detroit Board of Commerce was perfected at a largely-attended meeting of representative manufacturers, last week, and the bureau is planning a vigorous campaign for the extension of Detroit's export trade. The work will be in the hands of the same committee that had charge of the preliminary details, F. E. Fisher, of the Studebaker Corporation, representing the motor car interests, as previously announced.

A recommendation by the special tax commission appointed by Governor Osborn to investigate the question of taxation, that corporations be taxed on their intangible values, has caused some alarm among the car manufacturers, who are already making ready to oppose this plan when the commission's report is taken up for discussion in a series of public hearings at Lansing, in the near future. The car makers declare that the proposed plan is confiscatory.

Accessory Organization Grows

NEW YORK, N. Y., Oct. 14.—At a recent meeting of the Motor and Accessory Manufacturers held at headquarters in this city, twenty-five new members were enrolled, representing different interests in the automobile accessory field. This brings the total membership up to 247.

The following are the applications received into membership:

Automobile Supply Manufacturing Company, 220 Taaffe Place, Brooklyn, N. Y.

The Batavia Rubber Company, Batavia, N. Y.

Bower Roller Bearing Company, Detroit, Mich.

The Buda Company, Harvey, Ill.

Carnegie Steel Company, Carnegie Building, Pittsburg, Pa.

Detroit Electric Appliance Company, 264 Jefferson avenue, E., Detroit, Mich.

Doehler Die Casting Company, 187 West 9th street, Brooklyn, N. Y.

The Eagle Company, 98 Warren street, Newark, N. J.

The Esterline Company, Lafayette, Ind.

Falls Machine Company, Sheboygan Falls, Wis.

Federal Rubber Mfg. Company, Cudahy, Wis.

The Hess Spring & Axle Company, Carthage, O.

International Acheson Graphite Company, Niagara Falls, N. Y.

Jacobson-Brandow Company, 122 Columbus avenue, Pittsfield, Mass.

The G. Piel Company, 13th street and Boulevard, Long Island City, N. Y.

The Simms Magneto Co., 1780 Broadway, New York City.

The Start-Lite Company, 1502 Michigan avenue, Chicago, Ill.

Stutz Auto Parts Company, 221 West 10th street, Indianapolis, Ind.

The United Rim Company, Second National Bldg., Akron, O

Universal Tire Protector Company, Angola, Ind.

Universal Wind Shield Company, 1607-9-11 Prairie avenue, Chicago, Ill.

Voorhees Rubber Mfg. Company, 18 Bostwick avenue, Jersey City, N. J.

Waukesha Motor Company, St. Paul avenue, Waukesha, Wis.

Widmer Machine Works, 144th street and S. Boulevard, New York City.

Wolverine Lubricants Company, 80 Broad street, New York City.

Wilson Heads American Manufacturing

NEW ALBANY, IND., Oct. 16.—George H. Wilson has been elected to the presidency of the American Automobile Manufacturing Company, of New Albany, Ind. He succeeds Berton B. Bales, who retired several weeks ago. This concern has decided to broaden the scope of its products and in the future will manufacture a complete line of pleasure cars, consisting of runabouts, roadsters, touring cars, coupés and limousines.

Introduction of Power Wagons

By Hayden Eames

It seems to be a habit of the practical mind to try to stretch its own specialty to the solution of every problem it encounters, whether obviously fitted for it or not. For many years this tendency, directly or indirectly, delayed the work of introduction of power wagons more perhaps than any other. Those most interested in the introdution of the power wagon during these years were engineers; very few others were interested at all, and, in consequence, took the engineers' point of view on faith. For a matter of 10 years, hardly a month went by that we were not treated to the information that such and such an engineer had solved the power wagon question, whereas, as far as the engineer was concerned, it was already solved, as there is ample evidence to prove the superiority of the power wagon over all other kinds of road transportation, at least as long as 10 years ago. Whatever improvements the intervening time or the future may have made or will offer, the mere engineering problem could properly be considered to have been solved when the new method afforded superior convenience and economy over then existing methods without corresponding sacrifice.

The peculiar mental bias cited in the opening phrase, however, concentrated the attention of those interested upon the search for some engineering solution, and they were correspondingly diverted from any attempt to remove the true impediments to the introduction of the power wagon during that period, which were almost exclusively administrative, and psychological, and in a less degree financial. In view of the large number of former inventions which are publicly known to have gone through the same experience, the difficulty of diverting the attention of those interested as well as the public from the engineering question seems amazing when regarded in retrospect.

While the introduction of the power wagon has made some progress during the period named, it is still conservative to say that the surface has not been scratched. Power wagon failures are still being reported by people who are trying to use the new machine in the old way; who, unconsciously, are limiting the capacity of the power wagon by the practices of draft-animal days. The first electric pleasure vehicle I ever saw was supplied with a whip socket, for which the body-maker's only excuse was "Because we had always been in the habit of putting them on." A recent alleged failure of power wagons reported to me was almost as hopeless of cure as though the owner had insisted on putting oat-bins into his machine shop; in fact, the cause of failure was somewhat analogous. It is this that we have to contend with. It is mainly to overcome this mental attitude, directly or indirectly, that the Electric Vehicle Association of America was created—of course, as a means to another end, but, nevertheless, that is the direction in which its weapons have got to be directed if it is really to be of any service to its projectors. Unfortunately, it is not only going to be necessary to directly educate owners and prospective users of power wagons, but their employes, even to the drivers, who have in most cases got to modify their points of view and methods before the introduction of power wagons can be expected to be general.

Like much other labor-saving machinery, especially in the transportation field, the power wagon speeds the men up all along the line. The operators, although much fewer for a given product, have to work harder and faster, but almost invariably obtain their compensation from shorter hours, perhaps not in proportion, but still to an agreeable extent. The increased speed is the first thing the driver feels. It takes him some little time to find his own advantage.

A good illustration lies in a story which was told me by an Adams Express agent in Buffalo some 8 or 9 years ago. At that point and at that time, the Adams Express Company had the first really successful installation of electric vehicles. Owing to a poor selection of the size of the vehicles in relation to the routes covered and the service to be done, the station was not as economical as it could have been made, but it was at that time an exceedingly well-operated station, and in all probability was at that time, in spite of the above-mentioned handicap, delivering express packages more cheaply than it was being done anywhere else in the United States by any means whatsoever. When the wagons were first introduced, the drivers immediately felt the exactions of the greater speed; they felt themselves speeded up, and they were loud in their denunciations of the whole scheme. They rejoiced in every accident that occurred and took delight in the misfit electrical conditions under which, at first, the vehicles were charged. At the time I speak of, the whole station had changed. The drivers had discovered that instead of being dragged back from the last package on distant routes at a very slow rate by a tired horse, the electric express wagon now running light brought them back at even a faster rate than that at which it had been running during the day. As one of them said to me: "I can deliver all my packages now, and get home a half hour sooner than I used to." At that time, the express agent offered to buy a new team with brass-trimmed harness for any one of the electric wagon operators that would drive it, but it was rejected with scorn.

All this education takes time, and hardly anybody is addressing himself to try to bring it about.

Perhaps the commonest of all bad practices is that of applying the power wagon to a delivery route previously operated by a horse wagon of the same size, and limiting it thereto. The difference in the actual cost of operation between a given size of horse wagon and a gizen size of power wagon is seldom in favor of the latter, and this is true, also, of the first cost of the complete unit. The principal economical virtue of the power wagon lies in its character of labor-saving machine. Under almost all conditions the price of drivers is the largest single item of expense. Taking the station hands into consideration, the payroll is always the largest single item of expense.

Efficiency in Delivery

The problem of the successful user of the power wagon then lies in the question of "How much goods can I deliver per man per day?" or, "How much work can I do with a man per day?"

It does not seem to take an Isaac Newton to realize that if the work of a man operating the new machine is arbitrarily limited to only what he can do with the old, nothing is gained. In all regular delivery systems, the problem is not only to lay out the routes to fit the new machine, but to select the machine sizes so that the largest possible machine that can be fully loaded will completely empty itself over a selected route in a man's day's work. This extremely simple mathematical thought seems to be almost incomprehensible to the majority of power wagon users. In some express companies, and others, whose principal business is city transportation, certain routes have become a positive institution, and, although usually originally of an entirely arbitrary selection, are assumed to be as immutable as the value of Pi. This sounds like a joke, but it is anything but a joke to those of us who have been frequently called upon to demonstrate the superiority of power wagons over draft-animals. Those who have not had the experience will be perfectly surprised at the frequent high grade of intelligence which declines to rid itself of the inherent necessity of operating on these time-honored routes.

We are, however, occasionally treated to a refreshing case of independence and directness in the substitution of power wagons for horse service.

In the Fall of 1901, the Adams Express agent in Pittsburgh put in service at East Liberty a light electric express wagon, and in doing so gave instructions to the agent at that point, against the latter's protest, that he should lay off all four of his horse wagons, and do his work with the electric, that he (the Pittsburgh agent) would decide later whether he would allow him any of the horse wagons back or not.

This was certainly taking the bull by the horns; but, as the East Liberty agent's job was at stake, the result justified the risk, and only one wagon of the four was put back into service, and that only as an extra. Of course, the intention of this barnyard approach could easily have been defeated had the size and speed of the wagon been unsuitable to the particular service to be performed.

A good example of what it means to speed up, not only the operators, but the daily routine and methods, is afforded by the ordinary practices of our great express companies when horses were a rule with them.

I have before me a careful plotting of ten established routes of different express companies in New York City made in the spring of 1902. You will probably be surprised to discover that from the time the horses left the barn in the morning until they got back at night, the teams were standing still 40.4 per cent. of the time, the maximum idleness on any one route being 64.25 per cent., the minimum 27.25 per cent. At least 50 per cent of this is due to the fact that the gait of the man matched the gait of the horse. The draft-animal belongs to a slow age, and the man who drove him as a rule adapted himself to it.

Man Takes Horse's Gait

If any one is in doubt as to the reality of this effect, let him observe the Egyptian plowman with his water Buffalo. The ordinary plowman is slow enough, but the Egyptian's movements suggest the chameleon. The ordinary draft-animal operator grades up from this on the way to the operators of machines. But the accessory facilities have also been accommodated to the draft-animal, and are, correspondingly, impeding its successor. The methods of loading and unloading and of handling packages, the shipping room arrangements and routine, and even the unnecessary time, assumed to be necessary, even with the existing facilities, are all adapted to the gait set by the horse, and all tend to deprive the machine owner of his advantage; and, remember, these speeds are not set to what the horse can do or necessarily actually does, but what he *may* do. Long practice has subconsciously led to their adjustment to the uncertainties of the horse in spite of the goad of competition. If you have to allow a half hour's leeway in 25 per cent of the cases in which a horse has to make a 2 hours' trip, what is the use of trying to save 15 minutes of a half hour's loading time?

This, roughly, illustrates the subconscious mental process by which all these measures accommodate themselves to the horse, and may indicate, generally, why they have all got to be changed before the power wagon will be generally acceptable without question. Those who have been through the experience cannot fail to recall the immediate effect of the use of the power wagon toward remedying this condition. The difficulty is to get the first one purchased and properly used.

I have before me a plot of the far-East Brooklyn route of the New York Transfer Company, both with horse service, and with electric vehicles. This involved the operation of what is known as a route-wagon, and no opportunity whatever was afforded at the time to modify the route, or take any other direct advantage of a labor-saving character of the power wagon. During the trip the team stood still 30 per cent of the time, but the power wagon stood perfectly still only 22¼ per cent of the time. The actual difference between the idle periods of the two outputs was three-quarters of an hour, but the power wagon completed the service one and one-half hours before the team. Of course this wouldn't do.

The experiment was not made for the purpose of introduction in that instant, but, in combination with other available routes, indicated to the demonstrator at once the immense saving that could have been accomplished had the education of the drivers, and the speeding of the package handling, the proper arrangement of shipping rooms, and wagon interiors, to that end, and the reconciliation of wagon capacities and route arrangements been immediately begun. But, perhaps, it is too much to expect that the development of special mechanical facilities for loading and unloading will precede rather than follow the general introduction of the new method.

System a Great Essential

The reality of the impediment which present handling facilities interposes to the introduction of power wagons can be illustrated by a case I once came across of a high grade dry goods company in one of our largest cities, whose installation of electric vehicles could not be made to pay. Examination developed the fact that no effort was made to crate or handle the packages in the waiting room with any reference whatever to the respective routes upon which they were to be delivered, and that the routes were laid out with equal disregard to the shortest possible empty haul; following their practice with draft-animals, the wagons were driven to the opening points of the routes, and, extraordinary as it may seem, the packages were all taken out of the wagons, and spread along the beds of grass between the curb and sidewalk. Some of the wagons carried one boy, and some two boys—each with a large canvas bag. Each boy pawed over the pile of packages and selected and put in his bag the packages belonging to the block that he was to cover, and those that were left the driver took back into the wagon and drove to the point at which the boys were respectively expected to finish their bags. Rather than this, the firm should have abolished its entire wagon system and employed boys with bags to carry the packages to the destinations on public trolley cars.

To the credit of the owners I must say that they finally looked into it, and the difficulty was properly remedied with correspondingly successful result. This was, of course, an extreme case, and unusual in the use of the boys, and the sorting of the packages on the ground; but the shipping room arrangements were by no means unusual. In fact, inadequate loading or unloading facilities are almost universal. The simple convenience of a ready-loaded crate to slip into the wagon upon arrival is most uncommon, and such suggestions are almost invariably resisted—not for any reason, but because we haven't been accustomed to do so. It sometimes happens in large shops that packages of a certain large classification are of a size and character which admit of their delivery through chutes to the shipping room. It is almost invariably the case that by a slight change in the arrangements, the sorting of these packages according to wagon routes can be made once and for all on the floor where and when they are put in the chutes. But, as far as I know, it has heretofore proved impossible to induce anybody to do this, although I have yet to hear a valid objection offered to it in any case, and yet the delivery manager of such an organization often calls himself a business man, although he unhesitatingly keeps the most expensive unit of his investment standing idle, apparently, for no other object than to relieve the strain on his own ingenuity.

Many of these requirements could be made to improve the horse service if the horse himself had the endurance to stand it—a point that is frequently overlooked. As has often been said, there is no watt-meter on the horse, and, in consequence, he is generally worked more or less beyond his normal capacity, the loads and routes being more or less subconsciously selected to that end. To save this loading time, therefore, means to cut down the horse's rest, without which he cannot do the work assigned to him, but the power wagon needs no rest in the same sense, and it is a large enough investment to make it desirable to conserve this time.

In considering this general question of reducing delays and loading times, it is often overlooked that the day's mileage is a rough measure of the work performed by a unit in a given service. An hour's delay on a 5-ton horse truck, averaging say 2½ miles an hour, may be a large percentage of a day's work in that unit, but measured in dollars it represents only a third of the loss represented by a similar period of idleness in a 5-ton power wagon whose average running speed is 7½ miles per hour.

It is very hard to persuade the average user that the idle periods in the day's work in any way affect a comparison of the draft-animal and power wagon.

The reactionary effect of external conditions goes deeper, and is far more nearly universal than the mere lack of facilities in individual establishments. For example:

The Alley Limitations

The dimensions of many of the down-town alleys in Chicago put a definite limit on the truck dimensions that can be used therein, and nearly all trucks working in that part of the city load or unload in the alleys. The peculiar arrangement of the railroad freight yards in Chicago curtails the efficiency of all methods of highway transportation to such a degree as to greatly dwarf the question of their relative advantages. Those who have investigated this particular case closely state that, it is no exception to the rules that the conditions can be perfectly well met by a rearrangement of these yards with direct reference to the use of automobiles with a probable improvement of 150 or 200 per cent in their loading and unloading capacity. It is reported that the railroads themselves are alive to the situation, and are approaching the solution in a more or less dilatory manner with an entire ignorance of the expert knowledge that is available on this subject in the automobile field.

There are many analogous cases throughout the country; many of them can probably be partially met by special portable loading apparatus of one kind or another applied to the trucks themselves. Next to the increase of factor of safety on operating cost to be obtained by improvement in tire maintenance on the heavier trucks, there is perhaps no single field in which the designing engineer, strictly so-called, could play as large a part in developing this business as right in this field of portable loading apparatus and the design of trucks with reference to special service. This is one of the few departments of automobile knowledge in which there is anything yet to be learned from draft-animal practice, or, rather from the practices that existed during the draft-animal period.

Fruit Handling Very Poor

Up to date the handling of fresh small fruits at automobile speeds has almost invariably entailed loss, and it is ridiculous to suppose that a little ingenuity properly applied would fail to immediately meet this case to which the improvement in speed and certainty offered by the power wagon gives the fruit handler a most obvious gain.

Nearly all the cotton in the Gulf ports, and throughout the South, is handled by negro roustabouts. It is fairly cheap and hard to beat for economy, but it is uncertain and sometimes too slow.

The condition has been partly met by the extension of railroad spurs; but about 2 years ago I knew of a very considerable order for electric 5-ton trucks that was lost because portable jib-cranes could not be applied to them in season to meet the conditions.

More could, of course, be said on this subject, but the examples are sufficiently indicative of the class. In the work of development in this direction, there is still a little to be learned from the practice which prevailed in draft-animal vehicles.

Mechanical ignorance on the part of prospective users, of course, has got to be expected. At least in the electric field no one is in so fine a position to cope with this as the central stations, and many of them are doing yeomen's service in this direction; but we all remember the time when it was otherwise.

The first considerable installation of electric vehicles in this country was almost ruined because the Central Station manager in that particular instance looked upon the vehicle user as legitimate prey. It was an interesting thing to walk into the charging station at night and see a long row of red-hot cast-iron rheostats through each of which a vehicle battery was being charged in two groups in parallel and to know that the current was being obtained from a 110-volt d.c. circuit which was being metered at the customer's expense nearly three-quarters of a mile away. Even a persistent horse user cannot fail to sometimes discover something. He may have a nephew just from college. At all events, this enlightened proceeding caused the user to put in his own gas engine and generator, and, in consequence, cut the monthly cost of current per vehicle from $38.00 to $5.50.

It is hard to believe to-day that such a company, or such people, or such action could have belonged to an organization which is probably to-day doing more far-sighted work in the introduction of power wagons than any association anywhere, and many of whose members were even at that time actively alive to the prospect.

There are, of course, many minor considerations which tend to retard power wagon introduction, and some of them are of a very isolated character. For example: One user of electric livery wagons in New York still uses many horses, and he probably will as long as there is a sale for high grade coach horses, because he raises them and uses his wagons to break them in. This particular firm needs no instructions from anybody. They are as well informed on the economy of delivery, and as well organized, and as unprejudiced, as any wagon user we have come in contact with.

Then there is always the reactionary or interested delivery manager. I have in mind a case where electric trucks came to grief very largely, but not entirely, because the man in charge of them received a personal compensation for every horse wagon he was obliged to employ in excess of the electric installation. As a result of this situation an electric truck averaging about 7½ miles an hour round trip by cyclometer, found itself unable to deliver any more goods per day than a horse vehicle of the same capacity averaging 2½ miles per hour round trip by cyclometer. Whenever, as in this case, it looks as though the laws of nature were suspended to the detriment of the power wagon, it is a pretty certain indication that something of this kind is to be looked for. But apart from these minor, but almost universal, considerations which occur in endless variety, the principal obstacles will be found to be practically limited to those discussed more at length in the above paper.

Public Education Is Needed

The whole question of the rapid introduction of the power wagon to-day is one of public education. We have no right to look for any engineering advance so overwhelming as to relieve this condition in time to be of any great service in the work. The general lines along which experience has indicated this education to be necessary, I have endeavored to set forth above. No associations, no corporations, no individuals are in such a position to force this education as the central stations; and no one whatever, except possibly the team users, is likely to reap as great an ultimate profit by it. The liberal manner in which this central station business has been conducted during the last few years, and the local newspaper advertising involved thereby, means the availability of the press for educational purposes to a degree even greater than that justified by the public interest in the question.

The association seems to be thoroughly alive to this situation, and we have a right to hope that the next year will see results.

A few of the motor buses transporting passengers to and from Chicago depots

COLUMBUS, O.—Shields & Wiseman have opened a garage and repair shop at 241 West Fourth avenue, in this city.

COLUMBUS, O.—O. G. Roberts & Co., 933 East Gay street, have taken the central Ohio agency for the Stearns for 1912.

URBANA, O.—The Only Garage of Urbana, O., has taken the agency in Champaign county for the Ford 1912.

WHEELING, W. VA.—W. W. Price, proprietor of a garage in McCulloch street, will have an agency in this city for the Metz cars.

CANTON, O.—Monnett & Sacher, Canton, O., have taken the 1912 agencies for the Ford, Oldsmobile, Rambler, and Everitt lines for that territory.

OAKLAND, CAL.—Frank R. Fageol, distributor of Rambler cars in Alameda County has opened a handsome new salesroom on Telegraph avenue.

PHILADELPHIA, PA.—An announcement is made of the removal of the United States Motor Company to its new quarters at 216-218 Broad street.

PORTLAND, ORE.—H. L. Keats of this city has secured another agency. His latest acquisition is the Chase commercial vehicle, for which he has the northwest distribution.

HAGERSTOWN, MD.—The Hagerstown Garage Company, will handle the line of 1912 Pullman cars. The company has recently built a large garage on the main street of Hagerstown.

COLUMBUS, O.—A change in the management of the High-Seventh Garage, located at High street and Seventh avenue, was made recently when Norman M. Johnston assumed the management, succeeding J. W. Fritz.

COLUMBUS, O.—R. C. Westcott, 972-976 North High street, has arranged for the 1912 agency for the Regal. The territory covers seven counties in central Ohio, a portion of which will be covered by subagencies.

PORT HURON, MICH.—George Yokom's new garage on Military street, when completed, will be able to accommodate 300 cars. The building will be 50x100 feet and will be of concrete and brick.

PORTLAND, ORE.—Edward E. Gerlinger, of the Stoddard-Dayton Auto Company, has secured the distribution for this city and the adjacent territory on the Pathfinder car. In addition to these two cars he will handle the Federal truck.

PORTLAND, ORE.—The Oregon Brush Auto Company, local agents for the Brush line, and the Landy Auto Company, Portland agents for the Garford cars and the foreign Napier, have recently leased new quarters at 31 Alder street.

CLEBURNE, TEX.—The material for the erection of the new factory that is to be built here for the manufacture of automobiles, by H. E. Luck and associates, has arrived on the ground and the work of putting it in place is to be pushed.

COLUMBUS, O.—J. P. Adamson & Company, 35 West Mound street, Columbus, O., has taken the 1912 agency for the Dart delivery wagon, manufactured at Waterloo, Iowa. The territory embraces ten counties in the central part of the State.

BOSTON, MASS.—The United States Motors Company has taken over the Stoddard-Dayton branch. The management will be in charge of Frank J. Tyler, E. H. Lucas will have charge of the retail department, and E. P. Weber of the wholesale department.

WICHITA FALLS, TEX.—The Wichita Motor Company has received the machinery for the factory that it is erecting here to manufacture automobiles. The mechanics that are to be employed in the plant have arrived from Detroit, Mich. The company will at present devote its plant exclusively to the manufacture of auto trucks.

PRINEVILLE, ORE.—H. C. Farris, formerly of Moline, Kan., has recently made partnership arrangements with J. F. Jacker of this city. This company will conduct an express business in the vicinity of Prineville, Ore. Two two-ton Kelly trucks have been installed and will be used to transfer freight, baggage and express from Madras, Opal City, Redmond and other railroad points on the Oregon Central to Prineville.

BALTIMORE, MD.—The Lord Baltimore Motor Car Company, 1523-25 Retreat street, is making preparations to move the motor truck plant from the monumental city and will probably locate in York, Pa. Jacob Baumann, general superintendent, and John Luntz, Jr., proprietor of the factory, were in York last Saturday looking over a number of sites and interesting capitalists in a project to move the plant here. Messrs. Baumann and Luntz left Baltimore Friday morning at 11 o'clock and arrived in York at 4:30 o'clock in the afternoon in a three-ton motor truck via the Baltimore turnpike. The men experienced some bad roads on the trip especially between Cockeysville and Parkton, where the pike had been torn up for a distance of about 10 miles. The men made a stop of about an hour to repair the fan on the truck and an hour and a half at Parkton for dinner. The entire distance was made on high gear and the actual running time was about 3 hours, or at the rate of 19 miles per hour.

NEW ALBANY, IND.—The Borgerding Motor Car Company will sell the Ford in this city.

LOUISVILLE, KY.—J. M. Robinson-Norton & Company, have taken the agency for the Motor Wagon.

YORK, PA.—H. S. Nagle, of Wilkes-Barre, has taken the agency for 1912 line of Pullman cars.

KALAMAZOO, MICH.—Arthur Fiske and Harry Parker have taken the agency for the Lion automobile.

CHARLEROI, PA.—The Spencer Auto Garage has signed up the Franklin dealership for the coming season in this locality.

WASHINGTON, D. C.—After extensive alterations the Buick Motor Company has opened new salesrooms at 1028 Connecticut avenue, N. W.

TACOMA, WASH.—John N. Ball has recently announced the acquisition of the western Washington territory on the Columbia car, with headquarters in this city.

INDIANAPOLIS, IND.—Brandt Brothers, who have been agents for the Lozier in Indianapolis and vicinity for some time, have also taken the agency for the Hupp-Yeats electrics.

PHILADELPHIA, PA.—The Eastman Motor Truck Company has established temporary quarters at 1141 South Broad street, for distribution in Philadelphia and vicinity of the Wilcox Truck.

SEATTLE, WASH.—Realizing that the Pacific Northwest is a rich field for the commercial truck, the Mais Motor Truck Company, is about to establish the Northwest headquarters in Seattle.

WASHINGTON, D. C.—The Wilson Company, agents for the Cole and Krit, has leased the building at 918 Fourteenth street, N. W., and after extensive improvements, will take possession.

BALTIMORE, MD.—Plans are being prepared for the removal into new quarters by C. R. Mizner, Baltimore representative for the Oldsmobile. The new quarters, consisting of an up-to-date showroom and machine shop, are located at 1419 North Charles street.

MACON, GA.—Plans have been perfected for the transfer to this city of the Howard Automobile Company of Jackson, Mich. General Manager J. E. Keith of this company has announced that work will begin in a very short time upon a new factory to cost $200,000.

SEATTLE, WASH.—As the result of a visit of Chas. P. Henderson, general manager of the Henderson Sales Company, to Seattle, negotiations were completed with the F. H. Barshar Company, of 1107 East Pike street to handle the Cole products in Seattle and western Washington.

COLUMBUS, O.—Alleging debts in excess of $1,000 a petition has been filed against the Radio Manufacturing Company of Columbus, O., asking that the company be declared bankrupt. The Radio Manufacturing Company was recently formed to manufacture automobile parts and accessories.

SEATTLE, WASH.—Charles R. Williams, who is well known to the automobile fraternity through his 2 years' connection with the Northwest branch of the Winton Motor Car Company in Seattle, has recently established the Auto Brokerage Company, at 307 East Pike street.

TOLEDO, O.—The Willys-Overland Company, this week through its attorney Rathbun Fuller, filed with the city council of Toledo, a petition asking for the vacation of a number of streets and alleys in Cycledale addition. The company is now in possession of this entire addition to the city and as soon as the streets and alleys are vacated will erect a number of large additions to its plant.

WASHINGTON, D. C.—Uncle Sam is in the market for 2 motor-driven combination fire engine and hose wagons to be used in the Panama canal zone. Bids for furnishing the fire apparatus will be opened by the Isthmian Canal Commission in Washington, on October 30. Rigid specifications for the machines in question have been drawn up and it is stipulated the machines must conform in every particular with the specifications.

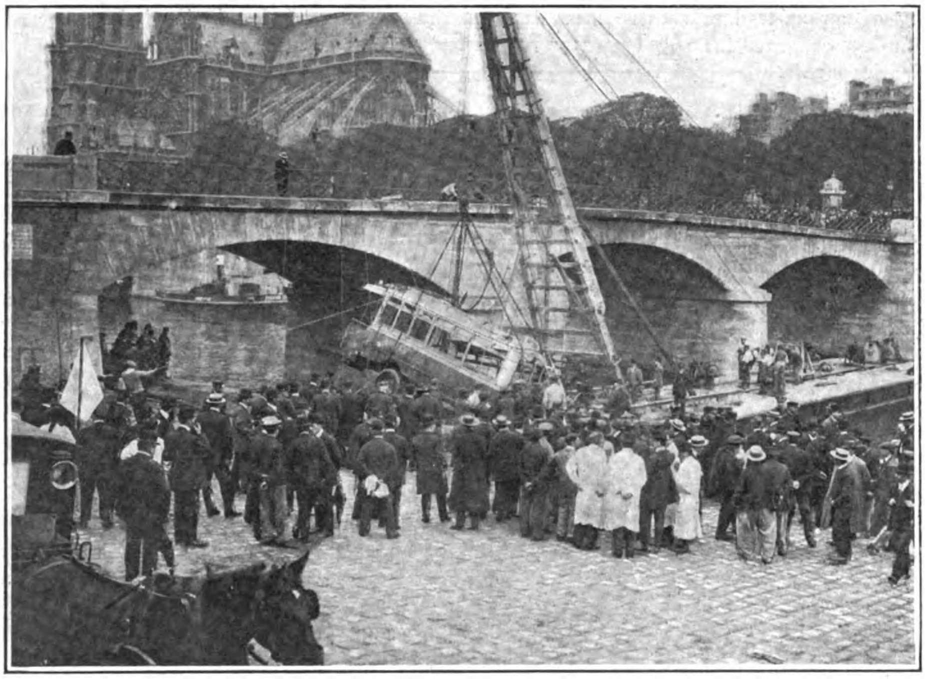
BALTIMORE, MD.—Plans have been made by the Mar Del Mobile Company for an extension of The Garage, Mt. Royal avenue and Charles street. The proposed addition will be 62 x 120 feet, which, with the present building, will give the garage a floor space of 100,000 square feet. This addition will afford a separate room for furnishing gasoline for motor cars in which a number of machines can be supplied simultaneously and a repair room with machinery and appliances.

INDIANAPOLIS, IND.—The Manufacturers' Bureau of Indiana, which includes in its membership 1,200 manufacturing concerns of the State, has taken up the question of organizing an employers' mutual liability insurance company. Companies writing employers' liability insurance in Indiana have advanced their rates 40 per cent. since January 1, owing to recent changes in the employers' liability law. The bureau has appointed a committee to report within 60 days some plan for forming a mutual company.

NEW YORK, N. Y.—Mr. A. Massenat, who has represented the Panhard and Levassor Company in this country for many years, formally announced his retirement from active control. Mr. Gustave Prost, who has for some time been connected with the concern, will take active control. He has been with the American Branch of Panhard and Levassor for seven years. Howard S. Hamilton will occupy the position of assistant manager and will have charge of the sales department, assisted by Herbert K. Levick.

KOKOMO, IND.—The Kokomo Rubber Company has been reorganized, F. I. Willis of Indianapolis, and G. H. Hamilton, until recently New York agent for the Continental Rubber Co., having bought stock in the concern. Officers of the reorganized company are: President, D. C. Spraker; vice-president F. I. Willis; treasurer, D. L. Spraker; secretary, William F. Langdon

The selling force of the Flanders company as it met at the New York headquarters



The recent automobile accident in Paris—hoisting up the auto bus which fell into the Seine

and sales manager, G. H. Hamilton. A reorganization of the Hearsey-Willis Company, of Indianapolis, has also been found necessary, F. I. Willis, who has been secretary and treasurer, becoming vice-president. Robert H. Colburn, has been elected secretary and treasurer of the company.

CHILLICOTHE, O.—The ArBenz Car Company is the new name recently adopted by the Scioto Auto Car Company.

MONTGOMERY, ALA.—The Drennan Motor Car Company of Jefferson County, has increased its capital stock from $5,000 to $50,000.

DETROIT, MICH.—E. J. Miles has been placed in charge of the experimental department of the Studebaker Corporation. He is a metallurgist of large experience.

CLEVELAND, O.—The Judd Automobile Company, 1206 Huron Road, has added to its general garage and salesroom a tire repair shop known as the Judd Tire Company.

DETROIT, MICH.—Joseph E. Warren has associated himself with the Metzger Motor Car Company and will be chief of district managers, under sales manager W. C. Hood.

MILWAUKEE, WIS.—The Smith-Hoppe Auto Company, 114 Mason street, has been appointed state agent for the R. C. H. car. The firm now represents the Hupp-Yeats electric, Oakland and Oldsmobile.

MEMPHIS, TENN.—H. R. Stone was appointed receiver of the Hazen Automobile Company by Chancellor Francis Fentress. A bill filed against the company by the Security Bank and Trust Company was declared a general creditor's bill.

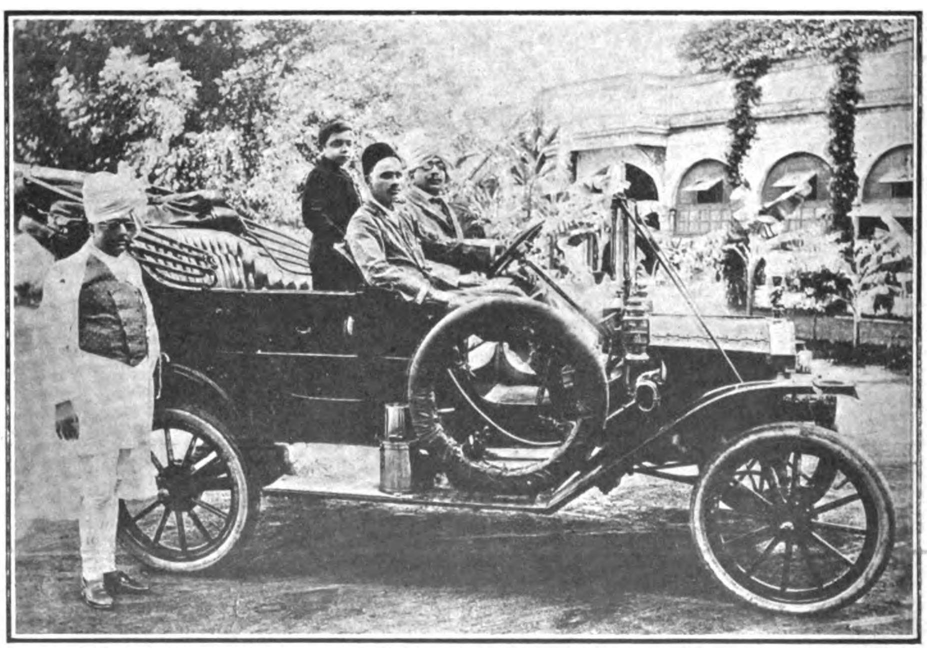
DETROIT, MICH.—The Goodfellow Tire Company has given a trust mortgage to Austin L. Richardson, as trustee, to secure creditors with claims aggregating $6,000. The mortgage covers the concern's plant at Woodward avenue and the Boulevard.

DETROIT, MICH.—The entry of the Ford Motor Company into the manufacture of light delivery wagons is one more example of the turning of attention to makers of commercial vehicles. The Ford delivery wagon is built on the model T chassis and uses the left-hand control as in the touring car.

CITY OF MEXICO, MEX.—It is reported that a syndicate of Americans, headed by L. H. Morrison, formerly of Indianapolis, will establish a large plant in Mexico for the manufacture of automobiles. Application for a concession for the proposed plant will be made to the federal government. The factory will be located either in this city or in Monterey, it is stated. The demand for automobiles in this country is rapidly increasing. At present many of the cars are brought from Europe.

MILWAUKEE, WIS.—A number of Milwaukee dealers took advantage of the opportunity offered by the holding of the International Dairy Show in Milwaukee last week to make exhibits for the benefit of dairymen and agriculturists. Among those who had exhibits was George W. Browne, State agent for the Overland; the Milwaukee branch of the Buick Motor Co.; Bates-Odenbrett Automobile Co., Abbott-Detroit, and the Charles Abresch Co., Halladay and Colby. The Abresch-Cramer Auto Truck Co. exhibited a line of commercial vehicles.

RACINE, WIS.—The Mitchell-Lewis Motor Co., of this city, has elected to come within the provisions of the new workmen's compensation or industrial insurance act passed by the last Wisconsin Legislature. The company employs more than 2,000 workmen. The law eliminates litigation and the incident expenses of suits and the industrial commission fixes the rates of compensation for injury and death from accidents in the line of duty. Motor car manufacturers as a class receive the benefit of exceptionally low rates in the schedule recently prepared by the commission, as the occupation is considered less hazardous than most other industries. The Mitchell-Lewis Co. is the first Racine industry to apply for the rights under the new law, which is optional with employer as well as employe.



The prince of Phaumagar, India, enjoys riding in a Ford which is driven by a native chauffeur

DETROIT, MICH.—A service department has been established by the recently organized General Motors Truck Company, with T. P. Myers in charge as general service manager.

SYRACUSE, N. Y.—The Syracuse Motor Car Company has the agency for the Ford output in this city and has just received a new style delivery wagon, it being a closed car of 20 horsepower and having a capacity of 700 pounds.

AKRON, O.—A meeting of Swinehart branch managers, salesmen and agents was held September 29 and 30, at the office of the factory. There were more than forty in attendance. Plans and the policy for the ensuing year were discussed and agreed upon.

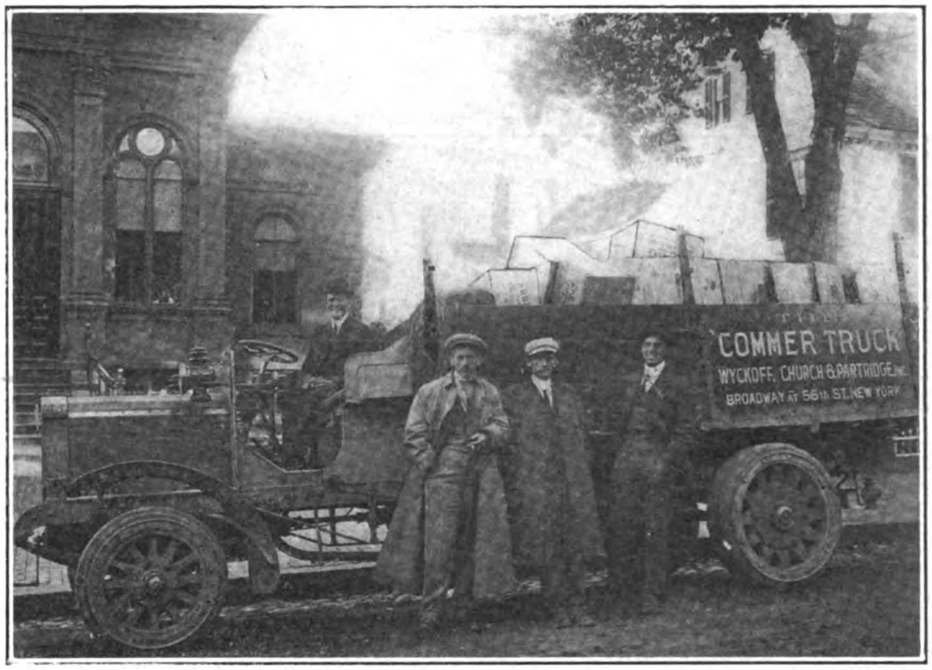
DETROIT, MICH.—S. L. Stone has tendered his resignation as assistant sales manager of the Oakland Motor Car Company, of Pontiac, to become general manager of the Centaur Motor Company, of Buffalo, which handles Oakland cars in western New York and Pennsylvania.

MILWAUKEE, WIS.—Leslie D. Flint has become associated with the Wisconsin Auto Sales Company, distributors for the Westcott, National, Herreshoff and Cutting. Mr. Flint will be in charge of the Westcott sales in Minnesota, Iowa, the Dakotas and Montana, with headquarters in Minneapolis.

JEFFERSON, WIS.—The Kenzler-Waverly Motor Company, a consolidation of the Kenzler-Waverly Motorcycle Company, of Cambridge, Wis., and the Waverly Motor Manufacturing Company, of Milwaukee, Wis., has accepted the proposition of the Jefferson Promoters' club to locate the consolidated works in this city. The plant will be in operation by December 1.

KENOSHA, WIS.—The Purdy Garage Company has been incorporated here to succeed to the business of the Kent Motor Car Company, which was recently purchased by Frederick Purdy. The Kent garage on Church street will henceforth be known as the Purdy Garage. C. H. Nellis, who was associated with the Kent brothers has joined the Purdy company.

CHICAGO, ILL.—The Chicago Motor Transportation Company, a $3,000,000 corporation, has dispensed with its horse-drawn 'buses between the depots and the retail section of the city and has introduced motor 'buses, each of which has accommodation for eighteen passengers besides the driver. These are pay-as-you-enter 'buses with a side entrance on the right and an exit in rear. The fare from the depots to any of the large stores is 10 cents. This is in strong contrast with a fare of 50 cents for horse-drawn cab service. The new 'buses operate on a regular time schedule over a definite route. The 'bus bodies are built on 1 1-2-ton White chassis.



The 4½-ton Commer truck which made a fine economy showing during the recent Boston truck contest

DETROIT, MICH.—The Studebaker Corporation entertained dealers from New York and the New England States during the past week, general manager Flanders acting as host.

SHERMAN, TEX.—F. D. Welch of Amarillo and P. M. Shelton of Grayson county have formed a partnership and opened the Sherman Automobile and Vulcanizing Company at 207 East Houston street.

Automobile Incorporations

AUTOMOBILES AND PARTS

BOSTON, MASS.—Amplex Motor Co. of New England; capital, $25,000; to deal in automobiles. Incorporators: I. B. Spafford, Wm. Turner, Wm. B. Foster.

BROOKLYN, N. Y.—Osgood Motor Car Co.; capital, $10,000; to make and deal in automobiles and supplies. Incorporator: Samuel H. Miskind.

CHICAGO, ILL.—South Shore Garage Co.; capital, $12,000; to deal in taxicabs and automobiles. Incorporators: Chas. M. Mudge, L. C. Zward, E. A. Fleming.

EVERGREEN, ALA.—Evergreen Motor Car Co.; capital, $2,000; to sell motor vehicles. Incorporators: C. P. Deming, H. W. Dunn and R. L. Whitcomb.

Fort Wayne, Ind.—Fort Wayne Auto Motor Co.; increased capital from $50,000 to $100,000.

GRAND RAPIDS, MICH.—Cogswell Motor Car Co.; capital, $10,000; to make automobiles and parts.

LAFAYETTEVILLE, N. C.—Consolidated Motor Co.; capital, $25,000; to make and deal in automobiles. Incorporators: H. Lutterloh, I. U. McKethan.

LINTON, IND.—Linton Garage Co.; capital, $10,000; to sell automobiles Incorporators: A. T. Custer, G. C. Porter, T. J. Holden.

NEW YORK CITY—Paul Lacroix Automobile Co.; capital, $10,000; to make and sell motor vehicles. Incorporators: Paul Lacroix, Harry U. Kibbe, Harvey T. Andrews.

NEW YORK CITY—Harger Steam Truck Co.; capital, $1,000,000; to manufacture and sell all kinds of vehicles. Incorporators: John S. Harger, Walter S. Wheeler, George F. Conis, James L. Weir, Gilbert E. Ofeldt.

NOWATA, OKLA.—Nowata Motor Car Co.; capital, $2,500; to sell automobiles. Incorporators: Walter K. Campbell, George Gordon.

OSWEGO, N. Y.—Motor Specialties Co.; capital, $175,000; to make engines and automobiles. Incorporators: Arthur Lovell, Howard H. Williams, H. V. Walsh.

PENDLETON, IND.—Forse Manufacturing Co., manufacturer of parts, increased capital from $25,000 to $40,000.

PETERSBURG, VA.—Overland Sales Co.; capital, $5,000; to sell automobiles. Incorporators: T. J. Burgess, D. P. Weeks, D. H. Burgess.

PHILADELPHIA, PA.—Wm. H. Godshall Co.; capital, $15,000; to make automobiles.

TOLEDO, OHIO—Ford Bros. Auto Sales Co.; capital, $10,000. Incorporator: Guy R. Ford.

WICHITA FALLS, TEXAS—Wichita Motor Co.; to manufacture automobile trucks.

AUTOMOBILE GARAGES, ACCESSORIES

BUFFALO, N. Y.—James G. Barclay, Inc.; capital, $25,000; to manufacture and sell accessories. Incorporators: James G. Barclay, Estella Barclay, George M. Kohl.

CAMDEN, N. J.—Eureka Double Resilient Tire Manufacturing Co.; capital, $25,000; to make automobile tires. Incorporators: Gideon S. Adams, Harry Fox, John B. Fox, Edwin S. Orr, George Clements..

CHICAGO, ILL.—Chicago Motor Omnibus Co.; capital, $1,000; to operate omnibuses. Incorporators: Henry P. Schandler, J. M. Johnston, K. Cornwell.

CHICAGO, ILL.—University Taxi Service Co.; capital, $2,500; to operate taxicabs. Incorporators: Frank H. Drury, W. Perry Hahn, Walter D. Launder.

CLEVELAND, OHIO—Broadway Garage & Livery Co.; capital, $10,000. Incorporator: Frank Paprock.

DONALDSONVILLE, LA.—Donaldsonville Garage & Automobile Supply Co., Ltd.; capital, $10,000; to do garage and accessories business. Incorporators: James P. Kock, A. A. Sarradet, Adolph Netter.

JERSEY CITY, N. J.—Sterling Top & Equipment Co.; capital, $50,000; to manufacture automobile equipment. Incorporators: Frank Grundy, Wm. C. Rands, George Copp.

NEW YORK CITY—Kelly-Springfield Rubber Tire Co.; capital, $10,000; to deal in rubber tires. Incorporators: Albert O. Briggs, Chas. W. Stapleton, Richard Condon.

PEORIA, ILL.—C. W. Haas Tire Seal Co.; capital, $50,000; to make automobile tires and rubber goods. Incorporators: C. W. Haas, R. C. Uckens, Emmet C. May.

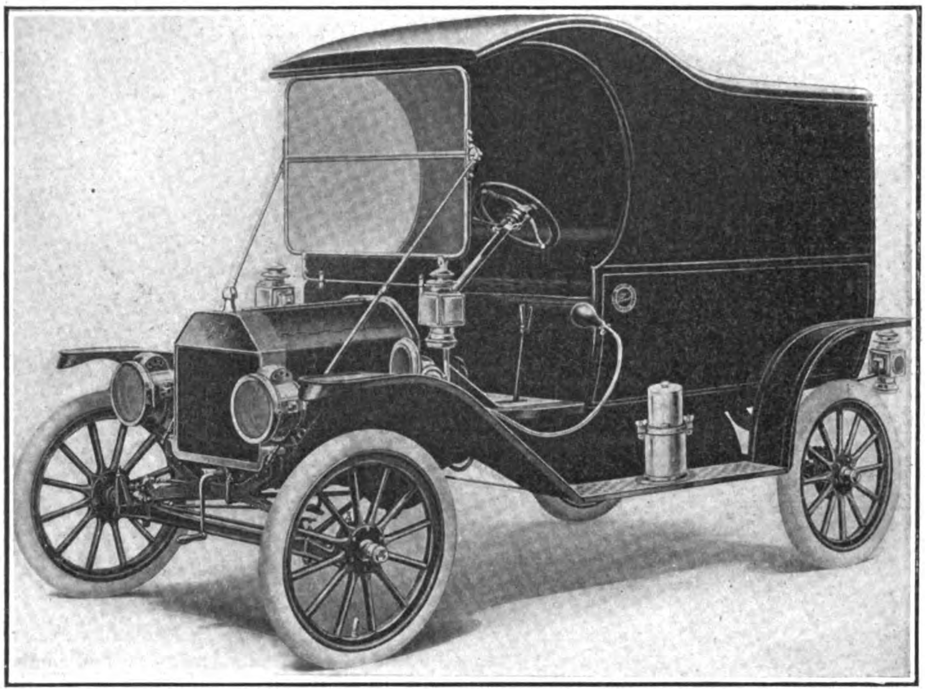
RICHMOND, VA.—Louis Bremm Estate; capital, $7,000; to build garage.

SAN DIEGO, CAL.—Savage Tire Co.; capital, $1,000,000; to manufacture steel automobile tires.

ST. LOUIS, MO.—Wrought Iron Range Co.; capital, $3,000; to build garage.

SHERMAN, TEX.—Sherman Automobile & Vulcanizing Co. Incorporators: F. D. Welch, P. M. Shelton.

OF INTEREST to the INDUSTRY



The new type of 700-pound delivery wagon constructed by the Ford Motor Company for the 1912 season

INDIANAPOLIS, IND.—Cole 30-40 automobiles will be handled by a number of new agencies among which are the Cole Motor Company, of Wichita, Kan., Ohnhaus Automobile Company, Fort Wayne, Ind., The Norcross Garage, Worcester, Mass., Central Auto Company Terre Haute, Ind., Curtiss Scofield, Newark, N. Y., Baker Bros. Motor Car Company, Buffalo, N. Y., The Penn Auto Company, Scranton, Pa., Burke Motor Car Company, Chattanooga, Tenn., C. A. Winter, Wellsville, Kan., Fred Bihl, 220 Dolorosa street, San Antonio, Tex., and The Philadelphia Motor Company, Philadelphia, Pa.

BALTIMORE, MD.—The A. G. Alford Sporting Goods Company, 212 East Baltimore street, has the exclusive agency for Ajax tires.

BALTIMORE, MD.—Among the latest cars added to the local field is the Cutting. The agency for this district has been placed with the Rice Garage.

FALL RIVER, MASS.—T. N. Paquin & Sons, South Main street, Fall River, Mass., have been appointed Kissel agents for Fall River and locality.

NEW BEDFORD, MASS.—A. E. Perron, 900 Belleville avenue, has been appointed selling agent for the Kissel cars and trucks for New Bedford and vicinity.

PROVIDENCE, R. I.—The Kissel Kar Company has been appointed selling agent for the Kissel line of cars and motor trucks for the city of Providence and vicinity.

KANSAS CITY, MO.—The J. A. Davis Motor Car Company has taken the agency for the Thomas line. Mr. Davis has been connected with President Chalfant of the Thomas company for over eight years.

AKRON, OHIO—Fred Kast has been appointed manager of the Cleveland branch of the Firestone Tire & Rubber Company. Mr. Kast is an Akron man and has for some time been at the Chicago branch of the same concern.

DETROIT, MICH.—The Ford Motor Company has recently established branches at Memphis, Tenn.; Los Angeles, Cal.; San Francisco, Cal.: and Vancouver, B. C. These cities will be Ford headquarters in the respective territories.

PROVIDENCE, R. I.—The Rhode Island Licensed Automobile Dealers have announced the date for the coming Providence show, which will be held in the Providence State Armory, from January 22 to 28. The main drill hall, having an area of 38,000 square feet, will be used to display pleasure cars, and half as much space will be devoted to commercials.

AKRON, OHIO—At the annual convention of the Firestone Tire & Rubber Company, which was recently held in this city, announcement was made that the factory which has just been completed at a cost of $1,250,000 will be devoted to the manufacture of tires while the old plant will be used in making rims.

NASHVILLE, IND.—Dr. F. L. Musselman. of Trafalgar, Ind., who recently purchased a sanitarium here, is planning to operate a motor 'bus line from Nashville to Bloomington, Columbus and Franklin, as Nashville is without railroad connections. A general motor car passenger carrying business will be conducted along this route.

BALTIMORE, MD.—Harry N. Baetjer and G. Ridgely Sappington have been appointed receivers for the Pullman-Shaffer Motorcar Company in the United States District Court here. The petition for the appointment of receivers was filed by the Chesapeake Tire and Rubber Company and the Baltimore Buggy Top Company.

CHICAGO, ILL.—The Cadillac Automobile Company, local representative of the Cadillac, has decided to erect a new five-story building at the northwest corner of Michigan avenue and Twenty-third street, opposite the Thomas branch. It is expected the new building will be completed by January. The lot is 75 by 165 feet and the Cadillac has a 20-year lease. The investment will total $275,000.

FINDLAY, OHIO—Another big plant in the Middle West will be added to the chain of properties constituting the United States Motor Company by the establishing of a special factory to manufacture parts for the Maxwell-Briscoe Motor Company, the Columbia Motor Company, the Dayton Motor Car Company, the Brush Runabout Company and the Alden-Sampson Manufacturing Company. A representative has already visited Toledo.

PHILADELPHIA—In the purchase of fifty Packard trucks by the Acme Tea Company there is recorded what is said to be the largest single order for motor vehicles ever placed in the United States if not in the world. The order was booked by the Packard Motor Car Company of Philadelphia. It calls for thirty three-ton trucks and twenty of the one and one-half to two-ton size. The purchase represents an investment of about $150,000.

BOSTON, MASS.—Charles G. Andrews and M. A. Dykeman have formed a partnership named Andrews, Dykeman & Company, to handle the Moon cars in the Hub. Mr. Andrews has handled the Moon as a sub-agency, but the new firm will have the entire New England territory. Salesrooms have been secured in the motor mart, Park square, formerly used by the Alco and Stoddard-Dayton agencies. Mr. Dykeman has sold, among others, Stevens-Duryea cars.

PITTSFIELD, MASS.—A special stockholders' meeting of the Jacobson-Brandow Company voted to increase the stock from $25,000 to $95,000, and it was decided to have five instead of three directors. Douglass P. Wesson, of the Smith & Wesson Company, Springfield, Mass., was elected a director and Harry G. Tucker, formerly with the Curtis Publishing Company, was also elected a director. The officers of the company are as follows: E. B. Jacobson, president and general manager; Douglass P. Wesson, vice-president; Harry G. Tucker, treasurer.

PATENTS GONE TO ISSUE

ENGINE-STARTER.—An apparatus operating by means of an air and fuel pump.

This device (Fig. 1), which is used in combination with an internal combustion engine and a source of fuel, contains an air pump which is connected to the engine and a fuel-measuring device connected to the source of fuel. The pump consists of a cylinder, piston and a manually operable plunger connected with the piston. The fuel measuring device is in shape of a valve having abutments which co-operate when the plunger is at its inward position, so that the valve may be turned by the plunger. The valve is adapted to discharge into the connections between engine cylinder and fuel supply.

No. 1,005,541—to Edward A. Halbleib, Rochester, N. Y., assignor to Northeast Electric Company, Rochester, N. Y. Granted October 10, 1911; filed December 16, 1910.

LAMP-DIMMING DEVICE.—Burner is movable by hydraulic pressure.

The construction protected by this patent is a combination of a lamp and reflector with a burner normally located opposite the reflector. The burner has a laterally projecting member, and by means of a fluid forced against this member the burner may be moved from its position opposite the light reflector. Means are also provided to limit the movement of the burner from its normal position.

No. 1,005,197—to Warren A. Greenlaw, Melrose, Mass. Granted October 10, 1911; filed January 3, 1911.

RUNNING-GEAR.—A method of chassis suspension for motor vehicles.

2. This patent refers to the combination of a frame, a front axle, an upper connecting member on the under side of the frame and a lower connecting member having its center housed within the upper member and its ends arranged over the ends of the axle. Through the centers of the members a sleeve is so inserted as to pivotally connect same, springs being arranged between the ends of the lower member and the axle, and bumpers between the upper and lower connecting members; there are also springs provided on the bumpers mentioned.

No. 1,005,171—to David M. Dearing, Jackson, Mich. Granted October 10, 1911; filed November 12, 1909.

LIFTING JACK.—Worm wheels and friction device are combined in jack construction.

3. This jack (Fig. 4) contains a standard in which a vertical lifting screw may be raised or lowered. A worm wheel is rigidly secured to the screw. A removable hanger is adapted to be mounted on the lifting cylinder or standard, and it carries a horizontally disposed worm which is operated by a crankshaft. The hanger also carries a friction device adapted to engage the crankshaft when the shaft is rotated in one direction.

No. 1,005,479—to Herrman A. Schatz, Chappaqua, N. Y., assignor to Acme Ball Bearing Company, Chappaqua, N. Y. Granted October 10, 1911; filed January 17, 1908.

CARBURETER.—Having two fuel reservoirs.

4. The carbureter (Fig. 5) to which this patent refers contains a main reservoir, a mixing chamber adapted to communicate therewith, a fluid inlet to the reservoir and a mixture outlet from the mixing chamber. An auxiliary reservoir is provided which has communications with the main reservoir and the mixing chamber; the auxiliary reservoir has an air inlet adapted to discharge air beneath the fluid level therein. There is provided a main air valve and a port of exterior of the air valve adapted to deliver a supply of air and fluid from the auxiliary reservoir to the outlet.

No. 1,005,491—to Alfred Weiland, Philadelphia, Pa. Granted October 10, 1911; filed January 21, 1909.

COMBINED SIGNAL AND SIGN DISPLAY LAMP.—System for automobile tail lamps.

1. The patent relates to a frame for holding individual interchangeable letter or number plates, comprising ends, top and bottom having parallel inwardly projecting flanges at their opposite front and rear edges forming longitudinal slideways for the plates, the top being provided with an opening at one end to admit one plate at a time into the slideway, a method of securing the closing means in place over the opening.

No. 1,005,306—to Almor Manor Puckett, San Antonio, Tex. Granted October 12, 1911; filed December 1, 1910.

INTERNAL COMBUSTION ENGINE.—Construction of the Diesel compressed-air ignition type.

1. The patent relates to the combination, in an engine of the type mentioned, with the engine cylinder, of a combustion chamber in which is arranged an atomizer nozzle containing a cut-off valve, which is normally held in closed position. A pump is provided to force a liquid fuel through the nozzle past the cut-off valve; an overflow valve is also provided, as well as an operating lever for the pump actuated from the engine shaft. On a stud is mounted adjustably an eccentric, on which again is mounted a regulating lever adapted to control the overflow valve. A link connects the regulating lever with the one controlling the pump, whereby overflow valve and pump are operated according to the speed of the engine.

No. 1,005,457—to Friedrich Oberhaensli, Bregenz, Austria. Granted October 10, 1911; filed November 28, 1910.

Newest Ideas Among the Accessories

Rapid Engine Cleaner

THE cleaner depicted in Fig. 3 serves for removing grease and dirt from parts of the automobile accessible or otherwise. One gallon of the cleaning fluid, which may be kerosene, gasoline or

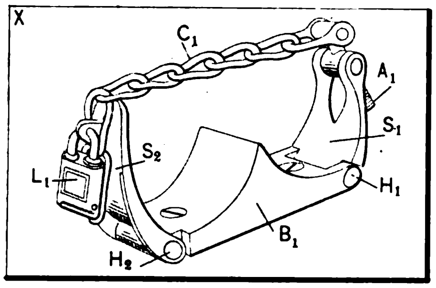

Fig. 1—B-A tire lock

tar oil, is filled into the tank through the filler hole ordinarily closed by means of filler cap F1, which is put in place after this operation. The tank is 20 inches high and has about 7 inches diameter. Then the pump P1 is worked, the air being led to the top of the tank where it presses on the liquid. This operation is continued until the gauge G1 on the top of the tank shows about 90 or 100 pounds. There is no difficulty in pumping up to this pressure in about five minutes, after which the tank is ready for use. If now the two cocks C1 and C2 are opened, the compressed air in the tank forces the oil up through the tube T1 and then through the hose H1 to the nozzle N1, where it is expelled in the form of a solid and fine but powerful jet. This will be efficacious in removing dirt, etc., if directed against the object to be cleaned. The

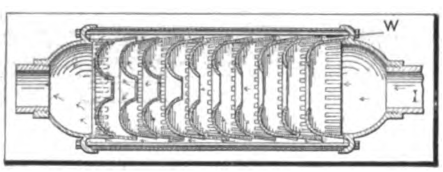

Fig. 4—Miller multi-chamber muffler

Rapid Auto Engine Cleaner is handled by Asch & Co., 1777 Broadway, New York City.

B-A Tire Lock

The device shown in Fig. 1 is the new tire lock made by the B-A Specialty Co., New York City, and marketed by Asch & Co., of 1777 Broadway, in the same city. Referring to the illustration, it is seen that the lock consists of a cast steel base B1 having a central divide to accommodate two tires. To this base two drop-forged shackles S1 and S2 are hinged at H1 and H2, and chain C1, which is of hardened steel, is fixed to S1 by means of the adjustable link A1. This chain is laid over the tires carried in the lock, and fixed to shackle S2 by padlock L1. The chain is long enough to accommodate any size of tires; the lock is finished in hard rubber.

Acme Torsion Springs

The Acme torsion springs, shown in Fig. 2, are designed to prevent road shocks and vibration from being transmitted to chassis,

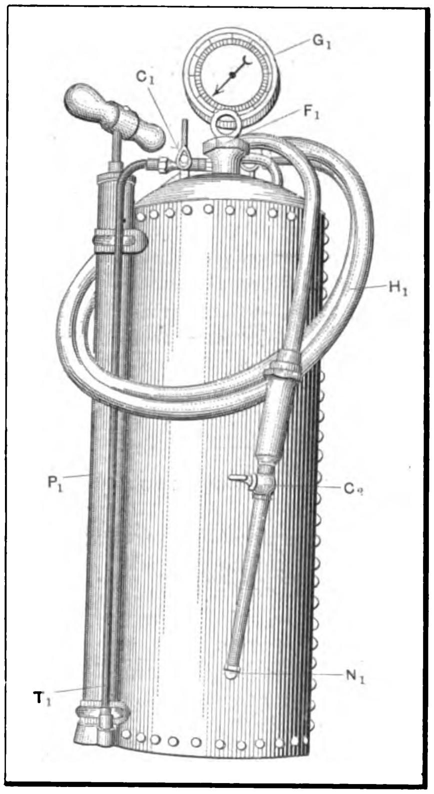

Fig. 3—Rapid engine cleaner

engine and body of the car, and to thereby relieve the tires of the shock absorbing service that is very frequently placed upon them. In the illustration Acme coiled springs are shown applied to the rear springs of the car, in place of the links connecting the leaf springs to the chassis frame. This work is easily done while the automobile is raised up on jacks, and the same bolts which hold the connecting links secure the torsion springs to the frame. It is necessary to lubricate the bolts copiously lest they suffer from the vast amount of work they have to do. The springs, which are manufactured by the Acme Torsion Spring Co., of Boston, Mass., are handled in the Metropolitan district by Frank Halpin, 9 Church street, New York City.

The Miller Muffler

The Miller muffler, shown in Figs. 4 and 5, is of the multi-chamber type and of cylindrical form. The exhaust gases of the motor enter on one end and after passing through eleven separate

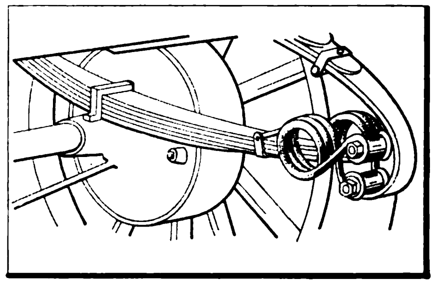

Fig. 2—Acme torsion spring

chambers leave at the other. The chambers are all of the same diameter, and stamped of steel in the shape of cups. As Fig. 4 shows, the entrance of each individual chamber is larger than its exit, so that part of the gases entering a chamber is bound to strike the rounded portion of the opposite wall, which is highly polished and imparts to the gases a whirling motion. This principle of operation is illustrated in Fig. 5, and the construction of the chambers forces the gases to leave them through the lateral passages and flow to the muffler outlet along the wall W (Fig. 4), because the central chamber outlets do not permit of passing of all the exhaust through them.

The whirling motion in the chambers serves to cool and expand the gases, and thereby to use up the inherent energy of the exhaust. Since the curved portions of

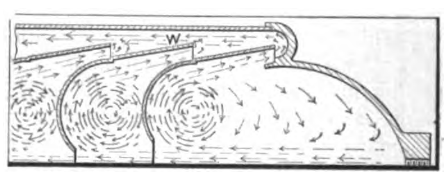

Fig. 5—Part section of Miller muffler

the chambers increase in size as the muffler outlet end is approached, the whirling motion would be continually increased but for the diminished velocity of the gases. The whirling effect is accompanied by a suction created in the chambers which tends to draw the exhaust into the muffler, thereby offsetting, to some extent, the back pressure caused by the same. In the last chamber no central opening is provided so that all the gas finally has to take the path leading along the muffler wall. The Miller muffler is manufactured by the Miller Silencer Company, Captain J. M. Miller, of 25 The Victoria, Washington, D. C.

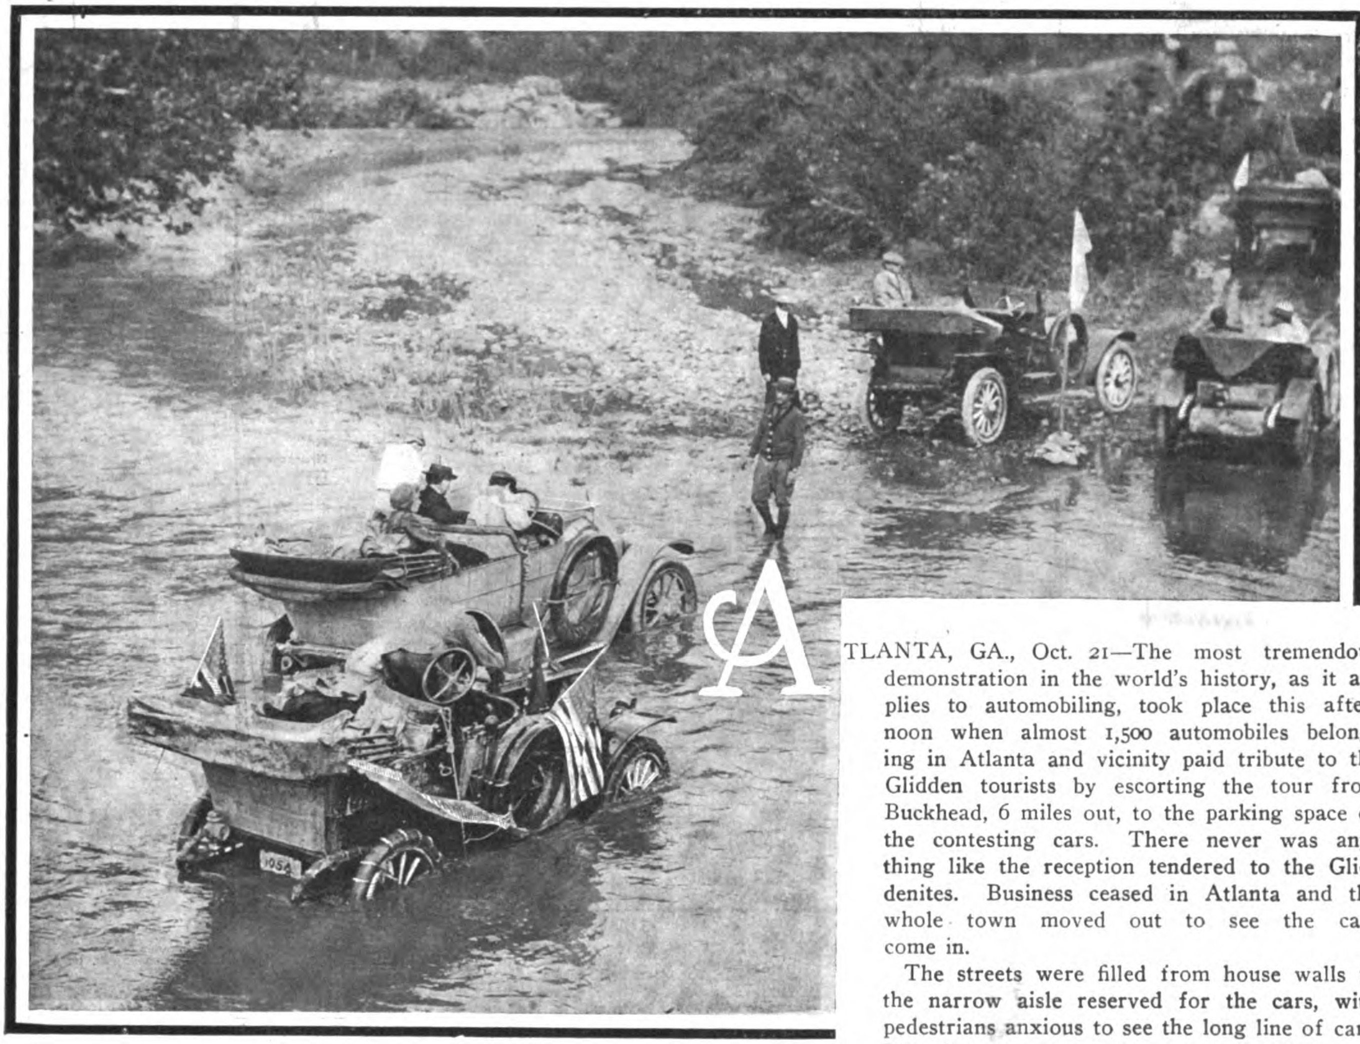
Maxwells Alone Perfect in Glidden



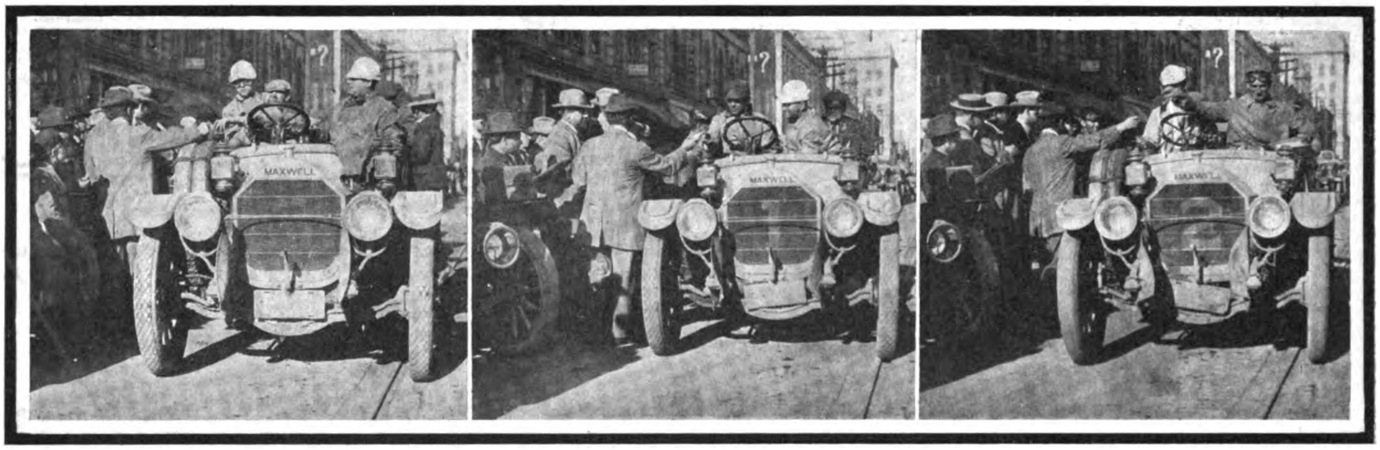
THE FORD OVER BACK CREEK STALLED A SCORE OF CARS

ATLANTA, GA., Oct. 21—The most tremendous demonstration in the world's history, as it applies to automobiling, took place this afternoon when almost 1,500 automobiles belonging in Atlanta and vicinity paid tribute to the Glidden tourists by escorting the tour from Buckhead, 6 miles out, to the parking space of the contesting cars. There never was anything like the reception tendered to the Gliddenites. Business ceased in Atlanta and the whole town moved out to see the cars come in.

The streets were filled from house walls to the narrow aisle reserved for the cars, with pedestrians anxious to see the long line of cars. The Atlanta newspapers devoted their whole front pages to the affair in preparing this city for the advent of the tourists.

It was a magnificent sight down Peachtree street with the Glidden cars moving sedately between solid masses of cheering citizens. On the other hand it was cruelly hard upon the cars themselves. They had just finished a long run in warm weather like July in New York, and many of them were short of water when they checked in. The course was long, and naturally the cars had to proceed at a slow rate with frequent stops and starts. The immediate result was that several of the contesting cars seized pistons and experienced overheating during the parade. The final results are problematical, but it is reasonably certain that several of the clean-score cars will suffer from the parade when they get into the deep Florida sands that are promised for Wednesday and Thursday.

The roads to-day were only fair. In South Carolina and in Georgia, on both sides of Commerce, the highway is largely unimproved, save for considerable grading. The schedule was not hard and only six cars suffered penalties. The chief of these will fall upon Oldsmobile No. 60, which broke its steering yoke and right front spindle north of Commerce. The car had just crossed a bridge and plunged into a chuck-hole. In trying to extricate it, the steering gear gave way. Case car 71 suffered much



The Tarrytown Maxwell team, which was the only trio that had reached Atlanta without being penalized

tire trouble all day and was not reported to-night. Oldsmobile 65 lost its clean score to-day, being delayed 17 minutes by tire trouble. The other penalizations were inconsequential.

It was a hard day on tires from start to finish, owing to the loose surface and lack of traction in numerous spots.

The Maxwell Tarrytown team retained its lead with a clean score for all cars composing it. Save for some minor adjustments that will be made on Tuesday's running time all the cars finished the day in just as good apparent condition as when they left New York. Just how much they were affected by the

‡Not reported at Atlanta night control.

The long line of cars stopped at Lexington, Va., to allow the tourists to inspect Washington and Lee College

parade through Atlanta remains for the Florida sands to tell. The Stevens team and the Cadillac team added nothing to their demerits and the Fords maintained their status. The Oldsmobile team is out of the running, although it is likely that all three cars will finish the tour.

Aside from the Maxwell factory team, the other clean scores are the following: Maxwell 4, American 5, Stevens 11, Mitchell 19, Thomas 22, Cadillac 32, Stevens 39, Cadillac 40, Ford 44, Ford 45, Cadillac 48, Columbia 49, Flanders 54, Mitchell 73.

Atlanta is taking more than a curious interest in the tour and the tourists. Upon arrival at headquarters in the Georgian Terrace Hotel, a magnificent new hostelry, the members of the tour were presented with engraved invitations from nine of the chief social and professional organizations of the city to make themselves at home in the various club quarters.

There was a dinner to-night at the Piedmont Club and on Monday there will be a barbecue and theater party, beside quite a number of less formal entertainments.

It has been estimated so far that the souvenirs, such as toilet accessories, cold-cream, tobacco and other small articles that have been heaped upon the tourists along the route, cost their purchasers not less than $2,000. They have been of real use. For instance, before reaching Charlotte a package was handed to each member of the tour containing toilet soap, talcum powder, toilet water and tooth-paste, all the gift of the local Y. M. C. A. Equally appropriate were a number of the other gifts.

After the fierce runs of mid-week, the last two days have been rather easy and quite monotonous.

One feature of the tour which is attracting deserved favorable comment is the work of the official cars. The Reo pilot cars have performed their work in a manner that leaves nothing to be desired, while the Cunningham pacemaker has met the severe test imposed upon it without flinching. Even the Chalmers press car, handicapped as it is with many pounds of over-fed newspaper men, has finished each day's run well up ahead of the line. The trio of baggage trucks—Marathon, Reo and Federal—are seldom far behind when the night control is reached.

60 Miles Through the Night

WINSTON-SALEM, Oct. 18.—Yesterday's wild race from Natural Bridge to Roanoke over seething roads and through a deluge of driven rain was discounted in its spectacular features by the night ride at top speed that featured to-day's run. Definite penalties were charged against 23 contesting cars, while seven failed to put in an appearance at night control up to the time the official report was made up.

The deluge of yesterday was so great that it was doubtful whether the cars would start at all during the day, but about 10 o'clock the word was given that the cars would be allowed to proceed as far as Rocky Mount without being checked out until arrival at that place. The difficulty lay in the condition of Back Creek, five miles from Roanoke, which was swollen to flood size. The cars forded this stream on their own power in large measure, but about twenty of them were stalled in midstream through the short-circuiting of magnetos and the flooding of carbureters. The column finally reached Rocky Mount around 4 o'clock and it was discovered that the checking out station had been moved along about 9 miles. The route up into the Blue Ridge was wonderfully beautiful everywhere except under the wheels of the cars. The hills were steep over Lynville Mountain and beyond, and except for short stretches the road was so bad that the cars barely crawled. The checking out station was 40 miles from Roanoke and 20 miles north of Martinsville, where noon-control was to have been established. Those 20 miles added the finishing touches to the majority of the clean scores, for they were all but impassable on account of the slippery going. Martinsville was reached just as night was falling. One by one the big blazing stars came out and the shadows from the wild woods swallowed up the moonless road.

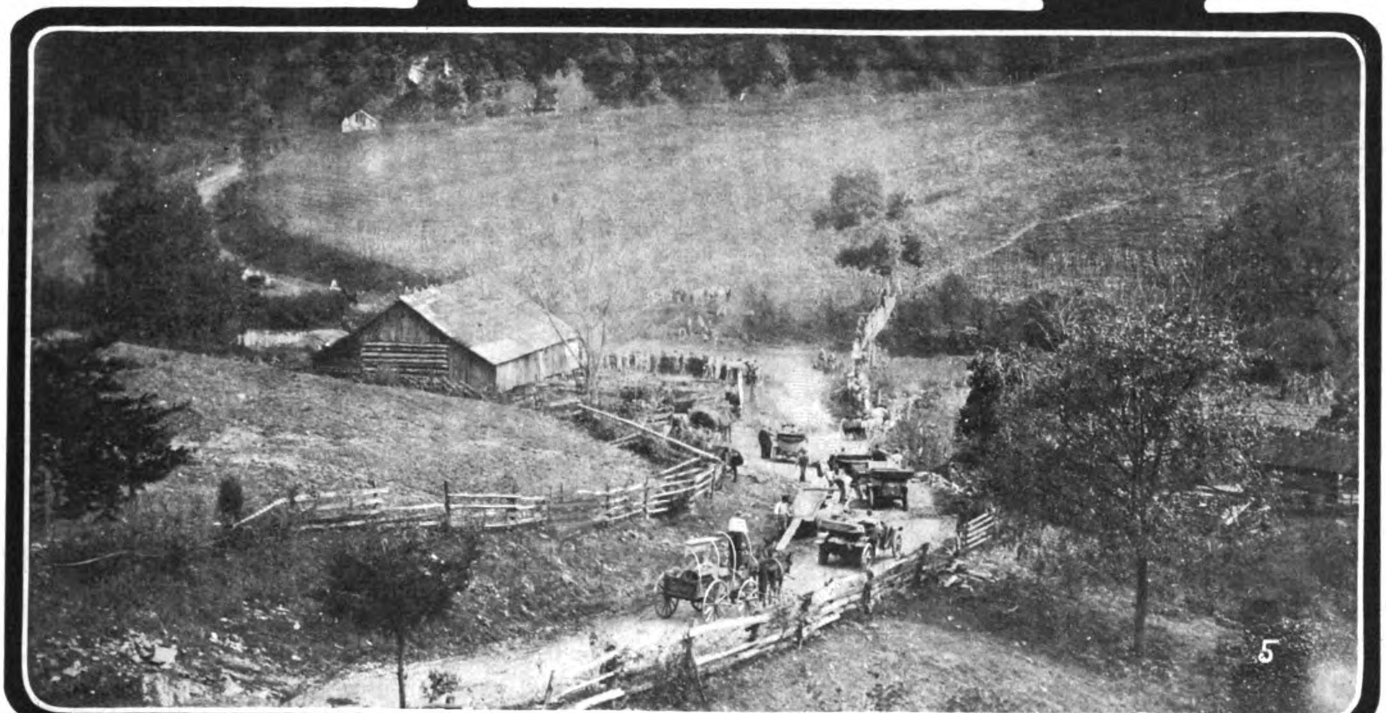
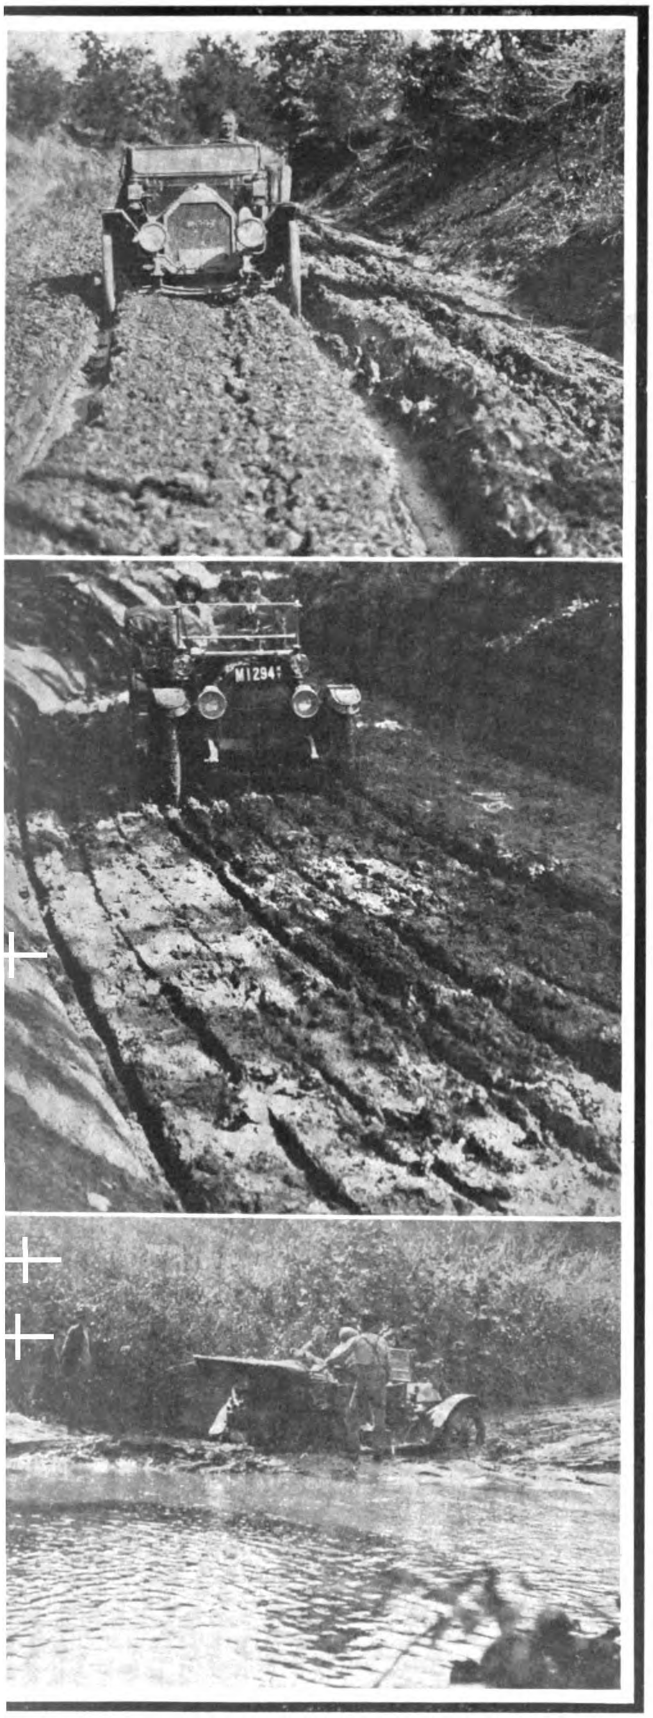
Continued Rains, Gave the Tourists Untold Trouble



5—Waiting on the hill for their turn to rush the diagonal ford
7—The cars that were stuck came out finally under two-mule power

6—Velie press car caught when only a few feet from the shore
8—After getting on the far bank the mule tractor came in handy



In the above pictures are given a few evidences of the manner which some sections of the South look after their roads. In ie top illustration Krit No. 70 is seen negotiating a particularly id stretch. There were miles and miles of roads no better than iat shown in the middle picture. The conditions outlined in the wer illustration are to be attributed to the excessive rains, the ect of water shown being merely an undrained road hollow. 'ow it impeded the cars is evident from the picture.

All around the horizon the peaks of the Blue Ridge loomed into the purple night and the breath of the trees supplied the inspiration for the marvelous run that followed into Winston-Salem. Sixty miles to the South lay the North Caroline city that was designated as night control and few of the tourists had ever been over the road in daytime, to say nothing of night.

The majority of the cars had from 2 to 3 hours left on their running schedule when they reached Martinsville and it was certain that scores would be decimated. But among the caravan were many drivers who would not say die and of these there are still a few with perfect scores.

It was a fierce drive over rough dark roads for full 20 miles and then the pike grew better and better until the spellbound passengers realized that they were whirling along at better than 30 miles an hour with grinning death just beyond the radiators. There were a few minor accidents but nothing of much moment, and to the astonishment of many a portion of the Glidden caravan finally reached control. There is a saying that the Lord is good to Glidden tourists and the members of the present run are willing to subscribe to that sentiment.

Despite the lateness of the hour, the whole city of Winston-Salem was out to welcome the travelers. Two bands played industriously and inside official headquarters at the Hotel Zinzendorf a galaxy of feminine beauty was gathered to personally welcome each new arrival. The drivers and in fact many of the passengers were treated as if they were heroes returning from a winning battle. At midnight Governor Smith made an address in which he voiced his well-known sentiment: "To Hades with the tariff; give us good country schools and good roads."

Some idea of the hardships encountered by the tourists to-day may be had from the statement that Governor Mann, who evidently knew what was ahead, side-stepped the tour through his State. If he had been within earshot of some of the tourists at the end of the day he would have in all probability registered a vow to get busy on good roads work at once. It is doubtful if the spectacle of 80 automobiles being dragged through muddy streams with the aid of Virginia mules will have a beneficial effect upon automobilists who contemplate traveling southward in the near future. Even the rickety old foot-bridge that was swung across Back Creek, where the cars were compelled to cross a diagonal ford, was in sympathy with the occasion, for while a crowd of automobilists were strung across it watching the passage of the cars through the turbid yellow waters, the flimsy structure emitted several warning cracks, and there was a lively stampede for either shore, according to which was nearer. Two men went through the rotten wood, but were grabbed by those nearest them and hauled up onto the bridge again. The passage of the ford by the 80 cars occupied at least five hours, and after getting through the contestants were compelled to negotiate 50 miles of as poor roads as can be found in these United States.

Nos. 6, 8, 17, 20, 42, 50 and 53 did not report at night control before midnight. Among the penalizations were: No. 7, 18 points; No. 10, 12; No. 14, 152 (making total of 1,133); No. 15, 130; No. 16, 57; No. 18, 10 (making total of 970); No. 21, 23; No. 26, 81; No. 31, 249; No. 33, 13 (making total of 100); No. 35, 228; No. 37, 3; No. 41, 33 (making total of 54); No. 46, 42 (making total of 46); No. 56, 153; No. 58, 34 (making total of 43); No. 59, 60 (making total of 65); No. 60, 81 (making total of 85); No. 63, 104; No. 64, 104; No. 66, 9 (making total of 19); No. 71, 117 (making total of 412).

Maxwells Assume Lead

CHARLOTTE, N. C., Oct. 19.—The trip from Winston-Salem to Charlotte, N. C., proved to be the most pleasant so far from a weather point of view. The start from the busy manufacturing center of Winston-Salem was most auspicious and it was seen by at least 1,000 college and school-girls who lined the sidewalks to witness the performance. The roads generally proved to be excellent as far as High Point, which by the way is a manufacturing center for furniture rivalling Grand Rapids. But when the Davidson County line was reached there was a different road story to tell. Davidson County is located in a rich cotton growing belt and is quite a distributing and collecting point for that staple, but its roads are neglected. Most of the penalizations that accrued to-day resulted from the bad condition of the highway near Lexington. North of Salisbury where the road passes out of Davidson county there is a startling change for the better, and from Salisbury to Charlotte the roads are fair to good, with some short stretches that rival anything in New York state.

The contest narrowed down sharply after Winston-Salem and the Maxwell factory team showed out in front with a clear lead in the race for the Glidden Trophy. All the cars, Nos. 1, 2 and 3, have clean scores, the team being the only one left in that category. Next in order comes the Stevens-Duryea team, consisting of cars 11, 39 and 66. The latter is demerited 19 points and the other two are clean. The Jacksonville Cadillac team is third with 23 demerits. This team consists of numbers 32, 40 and 47. The Oldsmobile team is fourth and the Ford team fifth. The others are so far out of it that they are not considered to have a chance.

The Metz team was heavily penalized for the run into Winston-Salem, one car breaking a wheel and suffering other injuries so severe as to necessitate its withdrawal. Both of the other members were late getting in and the team is out of the running. E-M-F 42 has withdrawn as the result of another broken axle. This car was equipped with a new kind of solid tires that did not lend themselves to touring over mountain roads. The only difficulty experienced by the car was due to the jolting of the solid tires.

The route of the tour carries the column through a series of receptions that are hearty and hospitable to a degree. At Charlotte open house was held at the Manufacturers' Club and at Salisbury the civic organizations did everything possible to make the noon stop pleasant.

To-day the town boosters were scattered all along the route, and each contingent seemed to be exerting itself to outdo the others in pressing gifts upon the travelers. Pipes and tobacco were furnished by one Winston-Salem firm. Other firms gave soap and vanity mirrors—these latter for the ladies only, of course—buttons, badges, flags, illustrated booklets, and other articles designed to extol the merits of their several towns. Many of the villages through which the tour passed had welcoming banners stretched across the roadway, each inscribed with hearty greeting. To-day's experience was a welcome one after the hardships encountered on yesterday's mud plug.

Nos. 16 and 72 had not reported at midnight. Penalties inflicted to-day included: No. 10, 14; No. 14, 1,000 (out); No. 15, 24 (making total of 154); No. 19, 21; No. 33, 62; No. 37, 11 (making total of 14); No. 53, 21 (making total of 612); No. 59, 58 (making total of 123); No. 60, 26 (making total of 111); No. 70, 45.

Seventh Day Uneventful

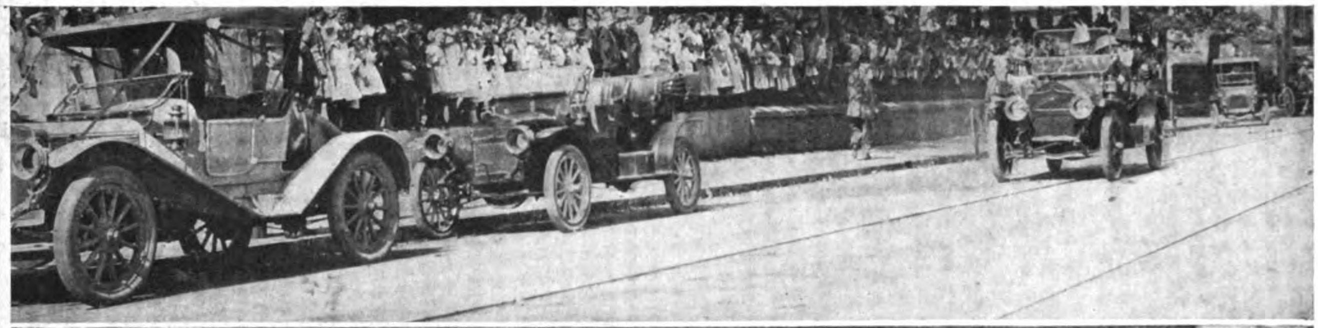
ANDERSON, S. C., Oct. 20.—The seventh day of the tour ended in the center of the cotton belt of the southeast. It is said that the territory tributary to Anderson raises a bale per capita for its population and that the giant mills use something over 30,000 bales more than the territory produces. The run was uneventful and the scenery did not possess the wild charm of the Virginia mountains, but the roads were excellent nearly all the way.

Like nearly all the towns used for night controls so far, the hotel accommodations for such a large party were inadequate. They were all right as far as they went, but did not extend any noticeable distance.

The Maxwell team maintained its lead and neither of the two teams nearest the front received any demerits. The Oldsmobile team, however, fell back a little and is now behind the Fords.

South Carolina furnished a pleasant surprise to the tourists

The above illustrations will give some indication of the hardships encountered by the contestants on the Glidden tour. In the upper picture is shown the Flanders No. 63 stuck in a 12-foot sandy rut, necessitating hard work on the part of the whole crew in order to extricate it. Rain persisted for nearly a week and every depression in the road formed a miniature lake. Nearing Atlanta the tourists encountered some excellent roads which were kept in shape by gangs of convicts.



Crowds of school children welcomed the Gliddenites on their arrival at Roanoke
The fire department at Natural Bridge, Va., is the proud possessor of a motor hose wagon, which came out to welcome the travelers

in the matter of roads. They had been led to expect that this state was far behind North Carolina in that respect. But the run of 160 miles from Charlotte to this place was over the finest dirt and macadam roads that have yet been encountered below Mason & Dixon's line. A couple of spills were the only features of the day's run. These were due to the speeding proclivities of a couple of Atlantans, who were evidenty so tickled at geeting on good roads once more that they could not help whooping things up a little. Anderson will never get far on its ability to take care of transient travelers, the accommodations here being so meager that in not a few instances a half dozen men were compelled to bunk together in one crowded compartment, which contained little or no facilities for removing the stains of travel.

Where the cars were parked overnight at Staunton, Va.

At midnight to-night Nos. 15 and 16 had failed to report. Among the penalized cars were: No. 7, which accumulated 9 demerits; No. 60, 39, and No. 71, 8.

From Atlanta to Cordele

CORDELE, GA., Oct. 24—The run to-day from Atlanta was over astonishingly good roads that have been built within the past year to a very large extent. For most of the distance of 167 miles the cars traveled over highways that seemed almost like boulevards when compared with the fairly good roads of the latter part of last week. Georgia is evidently alive to the value of good roads, and has accomplished a vast amount of work along these lines since the vogue of the automobile in the South.

When the cars reached Macon, 100 miles south of Atlanta by the national highway route, which was scheduled for the noon stop, the town was in holiday dress, and the streets were lined with thousands of citizens cheering the tourists as they entered the city.

One section of road encountered today attracted no end of favorable comment. Leaving Macon the tourists encountered 15 miles of broad macadam road leading across low, swampy ground, that under ordinary conditions, before the road was built, would have tested the cars to their utmost. This stretch of road is broad enough for four cars traveling abreast.

Case car No. 71, which reported so late at Atlanta Saturday night that it failed to get on the official report blanks and was ruled out unofficially, was back in the run to-day and received the only penalization imposed. It was nine minutes late getting into Macon.

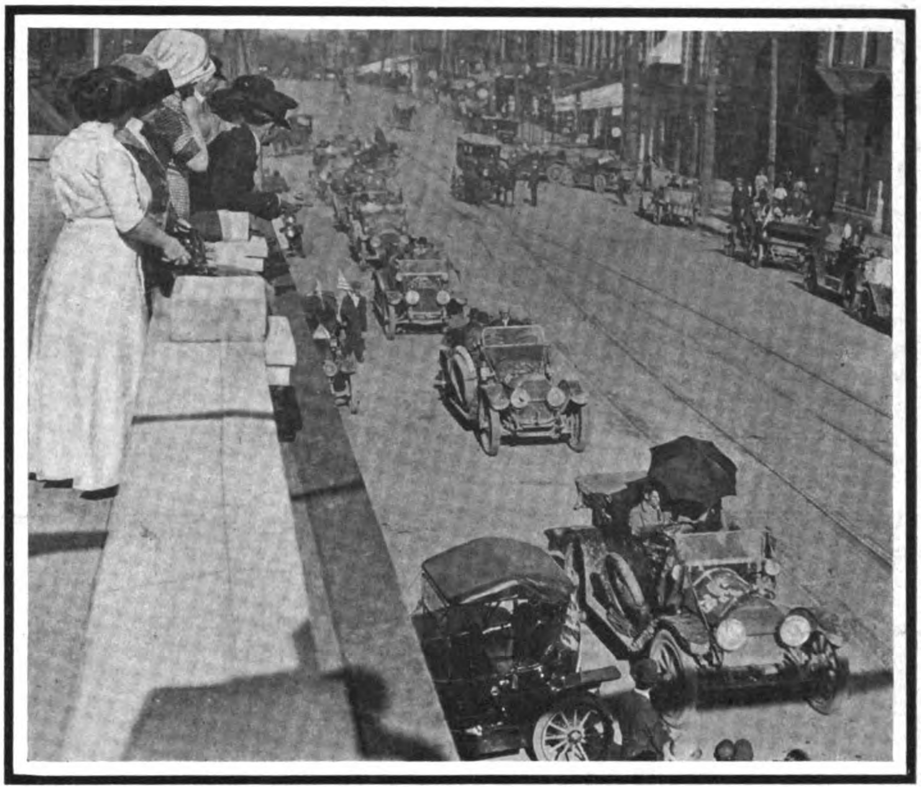
Pierce-Arrow No. 64, owned by E. Rivers, of Atlanta, was withdrawn by its owner who contracted a heavy cold during the rains of last week and on the advice of his physician abandoned the run.

White gasoline car No. 46, owned by Julian Howard of Jacksonville, failed to arrive here at midnight. Report has it that it is ditched somewhere near Barnesville, Ga., with a broken axle. Those in charge of the car have wired that they will be able to effect repairs in time to join the tour to-morrow.

What looked like an ugly accident occurred just before Macon was reached when Cadillac car No. 47 went over a railroad right-of-way into a 6-foot ditch. It was pulled out by a non-contestant and made the noon control all right.

Considering its size, Griffin, Ga., accorded the tour one of the heartiest receptions given it along the route. Such was the opinion of the tourists, at least; but their minds were disabused later on when they discovered that the uproar in the streets of the small town was due to the fact that a wandering circus had pitched its tents there for the day and thousands of people from the surrounding country had poured into the town to witness the parade preceding the performance. It is quite possible that the Griffinites were unaware of the passage of the Gliddenites till their arrival. During the afternoon the travelers were greatly entertained by witnessing the operation of manufacturing turpentine at one of the roadside camps.

One of the contestants in the tour, Capt. W. J. Hillman, of Live Oak, Fla., who is engaged in the turpentine business, gave an impromptu lecture on the various processes that proved decidedly interesting.



Checking in at the noon control at Salisbury, S. C.

This city to-night is ablaze with electric lights specially strung to celebrate the honor accorded Cordele by placing it on the itinerary as an over-night stop. All the leading clubs supplied the tourists with visitors' cards and placed their club houses at the disposal of the visitors.

All told, the participants of the tour feel perfectly content in respect of the welcome they have hitherto met all along their route.

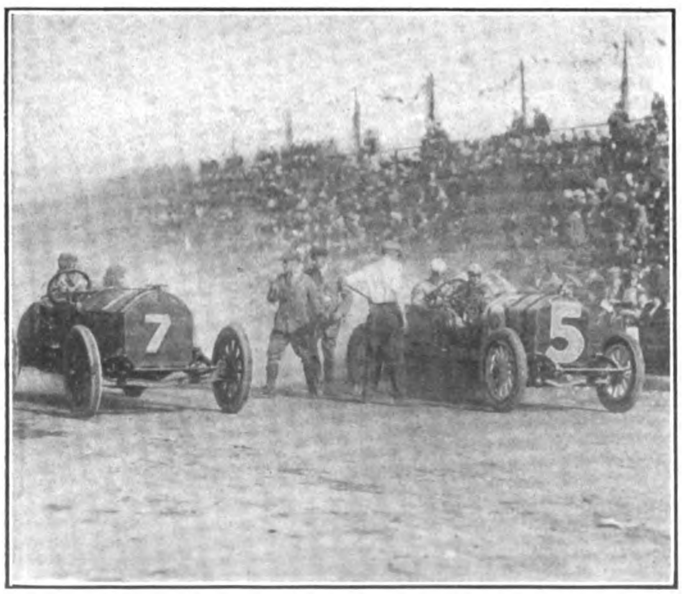
Line-up for the medium and heavy car events in the recent Santa Monica races, showing grand stand and timer's pavilion

Fast Time Marked Los Angeles Meet

LOS ANGELES, CAL., Oct. 22—The usual fast time marked the two-day speedway motordrome meet. Five thousand people saw Saturday's sport and 10,000 crowded the pie-pan to-day. The feature Sunday was the match race between Tetzlaff in a Fiat and Lee Oldfield in a second Fiat. Tetzlaff won two straight 2-mile heats in 1:18.57, and 1:17.9. These cars also hooked up in the two 5-mile free-for-all events. Tetzlaff won the first in 3:19.25. Oldfield was 4 seconds behind. The Inter-State, with H. Endicott driving, took third. In the second free-for-all Oldfield beat Tetzlaff in 3:20.33. Dingley in the Pope was third.



Start of the 301 to 450 class in the recent Santa Monica races

The 5-mile race for cars under 600 cubic inches piston displacement was easy for Bert Dingley. The Schacht also had an easy time winning the 10-mile 231-300 class, and the 25-mile race for the same class. Tetzlaff and Dingley fought out the free-for-alls Saturday. Both 5-mile races were fights, the Pope finishing a close second each time. Hanshue in the Mercer was an easy winner in the 10 and 25-mile races for his class. Dingley won the handicap, Saturday, and was beaten by Endicott in the Inter-State Sunday. Endicott had 13 seconds in 5 miles. Summaries:

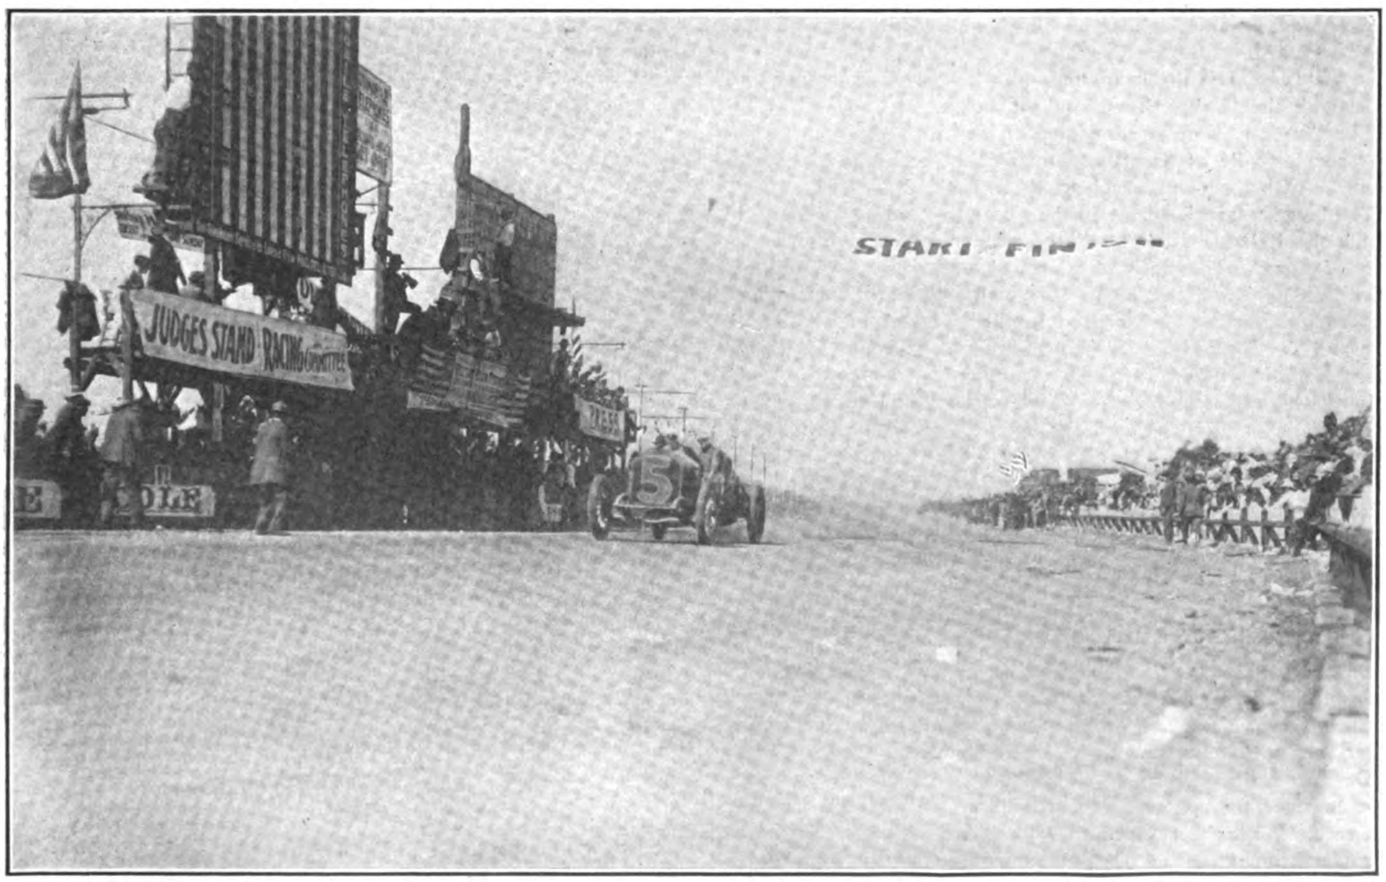
Herrick in a National beating world's record in Santa Monica race

Sealed Handicap at Long Island Club

The Long Island Automobile Club's first contest for the Schimpf Trophy will be held on Saturday, October 28, 1911, starting from the Club House, 920 Union street, at 1 p. m. At the suggestion of the Board of Governors, the first contest will be an easy one, practically a club run, with the award a matter of chance. The restriction in regard to the amateur status of drivers has been eliminated from the deed of gift and any member of the Club in good standing, who drives his own car, is eligible. There will be no restriction as to passengers to be carried by the cars.



Merz in the National at the finish of the 301 to 450 class race at Santa Monica, winning first place and averaging 74.42 miles an hour

REVISED OFFICIAL RECORD OF TRUCKS IN SAN FRANCISCO'S RECENT TWO-DAY TEST
